P. W. Henry, vice-president of the American International Corporation, evidenced the absolute necessity of curtailing the manufacture of certain products if the Government is to carry out its war program. The Government should work on the public and emphasize the need of its limiting its purchases to bare necessities in order that the Government may have at its command the men and material necessary to produce the articles it requires. To this patriotic appeal should be added a system of taxation so drastic as to compel every individual to curtail his expenditures for non-essentials. This would not mean the cessation of the manufacture of non-essentials, for these factories could still continue their business for export, which is necessary in order to stabilize exchange. There would be a slump, of course, but every manufacturer of this class must expect to have his plant put on part time sooner or later, and it behooves him to get in touch with the Government to find out for what articles needed in the war his plant is particularly adapted. He, knowing his business, should take the initiative in bringing the Government and himself together on a mutually satisfactory basis.

Wm. Hamlin Childs, president of The Barrett Company, declared that there is no such thing as a non-essential industry. The non-essentials will be taken care of by arrangement between the parties interested—in other words, they will take care of themselves. A good many plants will do different things from what they have done before, but they must be preserved to go back to their old conditions after the war is over. He did not believe there was a class of men whose spirit was more energetic for the public good than the manufacturers of this country, and they should offer, and continue to offer, their advice to the country until this question of the industries is settled right.

Frank Mossberg cited the case of industries which were willing to take on Government manufacture, but found it difficult to get the work. Many of the small manufacturers were not in the position to go to Washington to secure an order, and therefore, if the case of these could be brought to the attention of the Government, something might be accomplished.

He mentioned that in southern Massachusetts some 10,000 people were employed in the jewelry industry. He did not know what would become of these people if their factories were closed down. He thought that if, on the other hand, they were given other lines of work which would be of service to the Government they would work harder than before. That would surely be much better than stopping their work entirely.

C. R. McMillen, vice-president of the Union Bag & Paper Corp., suggested more earnest consideration of the need of industrial coöperation as the means to the economic betterment of business. He considered that all business may be divided into three classes—directly essential, indirectly essential and non-essential. All productive business is essential, and every idle dollar or person capable of productivity is a burden on the nation. Labor employed in semi-essential or purely non-essential business may be unfitted for the production of essentials, and if unemployed becomes a carrying charge, a cost, to the nation. It would be well for the Government to issue bulletins indicating kinds of experience or labor, materials, buildings, plants, machines, tools, etc., wanted, so that all resources may be utilized where and in what manner they are most needed.

J. R. Haas, secretary and treasurer of Loft, Inc., New York, entered an interesting argument for the classing of confectionery as an essential since it was a food. He said that in 1906, when the pure-food law was framed, candy was included in its operation, and that in the city of New York the Department of Health maintains a pure-food division which inspects candy factories, classing their product as food.

Erik V. Oberg made an able presentation of the manner in which the problem of the non-essential industries had been handled in England. In that country they have not forbidden any kind of business; on the contrary, all kinds of business have been encouraged to go on exactly as in peace time, provided they can do so without taking material necessary for war purposes. Such manufacturers cannot get iron and steel, nor practically any other metals, so that in the iron and steel industries very little is being done except war work.

Mr. Oberg also described how England had handled the labor problem under the War Munitions Act, not a paragraph of which but was not first agreed to by the Government officials, the manufacturers' associations and the labor officials in joint conference.

Ellis L. Howland, one of the editors of *The Journal of Commerce*, wrote that the answer to the question what are non-essential industries depended entirely on the viewpoint of the judge. No man who has worked hard to create a working entity which has served the public likes to be told it is non-essential. It is not in normal times, but when our national needs are distorted it may be truly dispensable as compared with the one thing needful. The decision must rest with one power, the Government, and with its superior opportunities for knowing all angles of the situation, hasty condemnation of its decrees is not to be encouraged. Once a decision is rendered, however, common sense ought to dictate that any upheaval of normal conditions should be made partial rather than total. With business men sharing in the responsibility of necessary adaptation, better results will be obtained than when inexperienced dictation prevails and practical opposition stands in the way.

He believed the best way to win the war was first to arouse and inspire the patriotism of the business man, coördinate him with the Government, get to a common understanding and above all a mutual respect and confidence, and then let the business man carve out his details as he will.

Sterling H. Bunnell said that it is impossible to win the war without hardship. It is not to avoid loss of profits by the manufacturer and his organization that any should protest against the limitation of the work of any plant or industry, but rather it is to avoid reducing the output of the United States. We need every ounce of effort of every citizen. The authorities should never stop a man's work in one line without putting him instantly into another job more necessary. This condition is an ideal impossible of full attainment, but its attainment is worthy of a strong and continued effort. Let us think of the situation as needing not the limitation of non-essential activities. In this way every plant and every organization available for any part of the essential work of the United States should be utilized, and then the few remaining non-essential industries could safely be left to take care of themselves.

D. D. Jackson, professor of chemical engineering, Columbia University, said he wished to correct the impression that the Government has forgotten the colleges, and has considered them non-essential. As a matter of fact the Government has asked the scientific schools to pick out one-third of their men and have them enlist and then return to the college to complete their scientific courses.

As an example of what might usually be considered a non-essential he mentioned photography. He said that under the auspices of the War Department a war school of photography had been established at Columbia, and was turning out a hundred men a month for foreign service. He thought there was no question but what every line of business could be modified so as to be applied directly or indirectly to war work.

At this point the chairman called for a brief, sharp discussion of what the engineer was going to do in this matter of the industries.

Spencer Miller, in responding to the request, said it seemed to him that so far the meeting had been somewhat one-sided. He vigorously assailed some certain things as non-essentials, and said that if we did not school our appetites and eliminate these we would lose the war and would deserve to!

He suggested a higher degree of specialization on behalf of our manufacturers. One manufacturer should not make more than one thing, and should let other manufacturers take the responsibility for making other things. If they would do that they would be efficient and could do essential things.

Finley R. Porter called attention to a situation which he thought ought to be looked into in connection with the matters under discussion. He said that at the outset of the war he tendered the Government the free use of his factory which is making automobiles, but while his offer was courteously acknowledged it had never been accepted. The Government apparently takes the attitude it wants work in large quantities. He knew of dozens—he might say hundreds—of factories that cannot possibly get work from the Government. Mr. Miller promised Mr. Porter that he would see he got some of it.

Charles W. Barnaby said his impression of the object of the meeting was that it was to arrive at the best means by which each individual manufacturer of non-essentials might switch over to essentials. He himself was connected with the mechanical side of the ship-equipment industry. They had plenty of work, and he imagined most of the shipbuilders had; and he thought that any manufacturers in the East who were prepared to make parts of engines and similar articles could get plenty of work from the shipyards if they only went after it or let the shipyards know where to go after them.

E. J. Hubaux, an American of Belgian birth, referred very feelingly to the manner in which the peoples of the stricken countries have had to revise their ideas of essentials and non-

essentials. He said that while it was quite true that certain things, like food and clothing, were essentials, they were so only when used sparingly—just enough, no more. He thought we should draw a lesson from Belgium, where if they have sufficient bread to eat so as to keep body and soul together, that is enough for them.

Our aim is to win the war quickly, and everyone must co-operate. If the jewelers cannot make jewelry they can make something else—time fuses for shrapnel or precision parts for torpedoes; those who are used to making pleasure automobiles can make motor trucks or aeroplane parts.

F. A. Clawson, formerly associated with the Imperial Munitions Board of Canada, thought the point of view taken by that board was worth bringing out, and that was that there was no manufacturer in Canada who was too small but what he could be made use of. In one instance the Canadian Pacific Railway Company was given a contract for manufacturing complete shells, and instead of doing all the work themselves they got other plants in the vicinity to do whatever they could to help out. One company they went to, the Northern Electric Co., of Montreal, had only five or six lathes! He urged the Society to bring this possibility to the attention of the Government.

He considered it of little use to argue whether there are non-essential industries—there are lots of them. The main point is to win the war. If the Germans win there will be neither essentials nor non-essentials!

Andrew M. Coyle thought that what we can do to bring our industries into better correlation than they are, with the least disadvantage to those that are non-essential and with the quickest results, is to get the small industries, like the automobile factory mentioned by Mr. Porter, into action and service by some system drawn up by a committee which this Society would recommend, and then bring the matter before the officers of the Government.

Selby Haar said that since this was a Local Section meeting, matters would be simplified if everyone who had something to suggest would write to the Secretary, who would see that the proper action was taken.

Secretary Rice said he wished, if possible, to convert the impulses of the meeting into action, and he suggested that each industry represented should form its war committee. They should then have a representative from this committee get in touch with either Mr. Waddill Catchings, representing the U. S. Chamber of Commerce in this work, or Mr. George N. Peek, representing the War Industries Board, and form a clearing house through these officials so that the non-essential industries should get a chance to manufacture the things the Government needs. He thought that by this means the end sought would be attained.

W. Herman Greul said that Mr. Rice had given the suggestion that should lead into definite action, and he therefore moved that the Council of the Society be recommended to appoint a committee to take definite action toward aiding in the solution of the problem of the readjustment of the industries, leaving it to the committee to determine how best to carry out its work, but following somewhat along the line suggested by the Secretary of creating a body to do something the Government, apparently, cannot do.

The motion was heartily seconded by Mr. Miller, who observed, however, that too much expectation should not be placed upon the ability of such a committee to make a very great impression at Washington, where the officials were already overburdened with thousands of suggestions. After a brief discussion, Mr. Greul's motion was carried unanimously.

FUEL CONSERVATION

With Special Reference to the Saving of Coal in Connecticut, as Outlined by Prof. L. P. Breckenridge, of Yale University, and O. P. Hood, of the U. S. Bureau of Mines

A CONSIDERATION of one of the country's vital war problems dominated the first meeting of the newly organized Connecticut Section, held under the auspices of the New Haven Branch on November 14 last. An account of the meeting appeared in the December 1917 issue of The Journal. There were two sessions, both devoted to the subject of fuel conservation. At the afternoon session Prof. L. P. Breckenridge, Mem.Am.Soc.M.E., delivered a paper on the Problem of Fuel Conservation, in which he presented some very interesting data on the production of coal throughout the world and also, in more detail, the production in the several states of this country. He illustrated his remarks by charts which he later exhibited at the Annual Meeting of the Society and which were published in the January issue of The Journal. The paper called forth discussion from Professors Seward, Perry and Barker, and Messrs. R. J. S. Pigott and A. J. German. Mr. T. W. Russell, fuel administrator for Connecticut, also participated. The following resolution was adopted:

Voted, That the Connecticut Section of The American Society of Mechanical Engineers instruct the chairmen of its several branches to name a committee on fuel saving for their respective localities.

At the evening session Mr. O. P. Hood, chief mechanical engineer of the U. S. Bureau of Mines, Washington, D. C., presented a paper entitled Fuel Conservation by the Bureau of Mines, followed by a number of slides of the new Bureau of Mines Building at Pittsburgh. His address was discussed by Prof. E. H. Lockwood, Mem.Am.Soc.M.E., Mr. C. H. Bromley, Mem.Am.Soc.M.E., Mr. F. O. Wells, Mem.Am.Soc.M.E., and Professor Breckenridge.

The meeting closed with an address by the then President of the Society, Dr. Ira N. Hollis, on the part the engineer is destined to play in the twentieth century in the service of mankind.

Extended abstracts of the papers and discussions follow.

THE PROBLEM OF COAL CONSERVATION

By L. P. Breckenridge, New Haven, Conn.

Member of the Society

(Abstract of paper)

THE importance of fuel conservation is evident to all. We in the Connecticut Section of The American Society of Mechanical Engineers, who represent the five largest and

most important cities of the state of Connecticut, might well spend some time reviewing some of the features of the problem to see if we cannot think of some plan by which we can save coal.

First, let us consider general methods. The continued improvements in boiler-plant equipment have meant a great deal in the economical use of coal, but when improvements in equipment can no longer be made, the employment of better methods of firing and operating must be considered. Better methods of operating mean economical use of steam, for a very large proportion of coal is used in the making of steam. Practically all railroad coal, all steamboat coal and all public-utilities coal makes steam.

The whole question of the economical use of steam has been before the mechanical engineer for forty years, and methods have constantly been devised whereby steam can be saved. But the manufacturers have not taken this question into sufficient consideration for the reason that coal has always been cheap and, in the operation of certain industries, has entered into the cost accounts in very small quantities. But at the present time, when the price of coal has gone up and the quality is so uncertain, and when equipment which was suitable for a fixed quality of coal must serve for a fluctuating quality, the economical use of steam will of necessity have to be given much more consideration.

The question of using power economically is a very complex one, in that it is so intimately connected with the question of heating, and thus it is very difficult to say just what should or should not be done. All the large public-utility concerns are today manufacturing power for much less than ten years ago. This they are able to do on account of the careful attention and study that has been given to the economical use of power. It is fair to say that power generated in the larger stations has usually been manufactured at a much less cost per unit of output than that generated in the smaller individual plants, especially at times when the question of heating the buildings is not of prime importance.

It has been suggested that one way of saving coal is by substituting another fuel. But the question is, What fuel? All the oil that we have is needed, and gas is scarce; wood is a luxury for it costs from $8 to $12 a cord, and there is little else left.

The matter of not allowing coal to be used for non-essential purposes has been suggested. But how can one list the purposes for which coal should not be used and for which it should be used? For example, the Government has stated that if lights in cities were dispensed with, 250,000 tons of coal would be saved for the entire United States. And yet there is no one city that uses over one per cent of its coal for illumination purposes. Such an action might have a psychological effect and, if so, much is gained. It is not so much a question of saving the coal because it costs but because we cannot get it. One-third of the tonnage carried on our railroads is coal. Forty-three per cent of the tonnage that comes into New England is coal. Thus we should first devise means of *getting* coal, and then later the question of using it for essential purposes can be taken up.

This brief consideration of the general methods of coal conservation will help us to devise a plan whereby coal can be saved in Connecticut. The five branches of the Connecticut Section of The American Society of Mechanical Engineers represent five very important industrial cities. As a possible suggestion the chairman of each of these branches could appoint a fuel-saving committee consisting of three members who are familiar with the situation in their respective localities. These committees should put themselves into such a position that they could help, if asked, and would coöperate with the Government committees working on the same problem. For example, the New Haven committee might be asked to make a census of the industries in New Haven in order to secure figures as to how much coal they are using and to ascertain if they care to have some one come to their plants to look over their problem.

Again, a publication of the requirements of the fuel problem might be undertaken. A vast store of valuable material has been compiled by the Bureau of Mines and is available on application.

DISCUSSION

H. L. Seward emphasized the importance of keeping records in order to save coal, especially in the smaller plants. The large plants keep good records, and are more careful about such things, but for the sake of the smaller plants such records should be installed. No record system will be of much use unless one knows just what things to record. Some simple form can be devised on which can be stated the amount of fuel and water used. The total amount of coal can easily be recorded by counting wheelbarrow loads. When the daily forms are studied, the amount of coal used, the ratio of water to coal for a particular plant, and the operating conditions, can be easily ascertained.

Any system of records is bound to increase the responsibility of the man operating the plant. If he signs a report as to the basis of operation and repairs made, he knows that just where the responsibility begins and where it ends can be easily checked.

Perry Barker believed that in connection with the conservation of fuel in factories equipped with steam boilers, the question of the fuel loss which occurs in the operation is a matter which should receive attention, and which will ultimately show what saving can be made.

In the distribution of heat in the operation of a steam boiler, first, a large percentage of heat comes off in gas and is absorbed by the boiler; second, there is a large loss of heat up the stack during combustion; third, there is the loss due to unburned gas; fourth, there is the loss of combustible material in ashes and the material removed from the grates, and lastly, there is the loss due to radiation from the boiler.

These losses can be divided into, first, necessary losses, and second, those which can be controlled. The gases have to leave the boiler at a temperature at least as high as that of the steam in the boiler. All heat above that temperature can be cut down. By a brief computation it can readily be seen that there is a great loss of energy in a boiler plant; only about fifty per cent of the heat in the fuel goes into the boiler, and fifty per cent is lost. Seventy-five per cent of that fifty per cent could be controlled. Simple methods either in changing the form of operation or changing the equipment have reduced it 10 to 50 per cent in certain cases.

The three principal controllable losses are loss of heat up the stack, the loss due to unburned gases, and loss in the ashpit.

In considering the stack loss and the unburned-gas loss, the process of combustion should be reviewed. Coal is thrown into the fire and products are distilled off and pass through the furnace. They are burned with the air that comes through the grate or over the fire, and should go out of the stack at the boiler temperature. However, if in their passage through the furnace they do not come into contact with sufficient air or are

improperly mixed, or have their temperature suddenly reduced, they leave in an unburned condition. This is an incomplete combustion, not that of mixing gases and air, but the incomplete combustion due to the gases passing up the fuel bed. This is the well-known water-gas reaction. The carbon dioxide formed in the fuel bed passes forward, is reduced to carbon monoxide, and that in turn passes through the furnace. This sounds somewhat foreign to boiler operation, but it is surprising to find that on careful analysis many cases which were believed to be due to insufficient air supply are due more directly to the process outlined above. By examining the composition of the average fuel gases, we see that there is a possible fuel loss of over 16 per cent. Figures on the analysis of gases through the furnace show the combustion loss to be six-tenths of one per cent.

What can be done to control the loss of heat in boiler operation? The three different elements concerned are: first, the type of fuel used; second, the firing efficiency, and third, the design and equipment. In these times we cannot complain about the kind of fuel. The fuel is very inferior, but it is all we can get. Some New England plants are adapting themselves to the use of the coal they now have to use, and it is a patriotic duty as well as a necessity.

As to firing efficiency and equipment, these are very poor times to go into the market for new boiler equipment. Boiler and heating changes which can be effected in any plant are purely a matter of expediency. In a plant where the boilers were run ordinarily with about 10 per cent carbon dioxide, there was a fuel loss of about 4 to 5 per cent. The boilers were raised about 2 ft. and some arches put in, and they have since maintained continuously 14 per cent carbon dioxide with no trace of unburned gas.

Another element which makes for poor boiler efficiency and which can be easily reduced is leaks and dirty water receptacles. Those are the places to look for trouble when the temperatures are high. The question of air leaks in the boiler setting is another item which of course has received the attention of all. As good an instrument as can be found in the small plant for testing this is a lighted candle passed over the outside of the boiler once a week.

In conclusion, coöperation between management, engineers and firemen is one essential feature in the conservation of fuel. There are hundreds of engineers who are ready and willing to report the conditions under which their fuel is used if they have the proper backing of the management and the available material by which they can interpret the results which they obtained.

R. J. S. Pigott said that the fuel situation had simmered down to a question of boiler operation and better methods of combustion. In this section of the country the best way to insure this is to use the underfeed-stoking method. During the last five or six years the use of this has grown with leaps and bounds, the reason being the much better method of combustion which is obtained. The old feeds on such coal as we now obtain would be even less satisfactory. As an instance of what the difference is, Mr. Pigott said he knew of a station that changed to underfeeds on some boilers and whose coal factor dropped 12 per cent as soon as the change was made. The station was one of the best-operated ones in the country, but it could not compete with the underfeed.

Two of the principal features of the system are that there is a proper mixture of air and a higher temperature during the period of combustion. The air is blown through the fire so it has a chance to mix with the gas on its way to the surface of the fire, and the lumps of coal act as a mixer. Then in its further passage it maintains a higher temperature while combustion is going on, and the use of equipment resolves itself into a matter of extensions, and the only way we can put in suitable equipment now is to put in extensions. We must turn to the underfeed stoker, and for industrials, at least, great consideration should be given to turbines and making use of low-pressure steam instead of high-pressure. There is no engineering excuse for the use of high-pressure steam in power plants such as we find all over the New England states. Most of our operations could be carried on with low-pressure plants as well as with high-pressure plants.

We find operation after operation run on high-pressure that can very well be put on low-pressure steam. We find dry kilns and other operations allowed to run over the Saturday and Sunday rest periods, thus wasting the steam. In one plant in Bridgeport the over-pressure load on Sunday is maintained and wasted. The use of steam in other connections can be made equally wasteful. The use of steam engines in shops should be discouraged; it is much better to develop all the power in a central station than to have the engines scattered all over the shop.

A. J. German believed that at very slight expense coal can be burned more economically in a furnace by sloping the brick wall of the furnace instead of having it straight. By having the wall straight it becomes very hot, and all the gases that are coming up, instead of having a free passage, strike the wall and ignite. The condition of the combustion can be improved very simply in this manner.

Another way of saving coal is to try to find the number of boilers that can most economically carry the various loads. Take a factory load that is fairly constant during the day and is less constant at night. There are a number of boilers in the factory, and the question is, How many are the most economical? That must be found out by testing the whole plant, and the best thing to do is to start with the full number of boilers and cut down one boiler, then run through the week and average the coal used. Then cut down another boiler, and so on, until the number you can run most economically to carry the varying load is found.

T. W. Russell, State Conservator of Coal for Connecticut, said that every communication from Washington on the general situation is to the effect that there will be enough coal to go around provided the maximum possible amount is mined, and then the largest possible efforts made in the way of economy and efficiency. Here at this end of the line there is nothing we can do to increase the production at the mines. The increase at the mines is rather sharply fixed by the physical limitation of the number of coal cars, and the underlying cause of possible fuel trouble in this country is the physical shortage of coal cars. Therefore it seems at this end of the line we must devote our efforts toward securing more equal distribution of coal, and that the greatest efforts and most fruitful efforts can be put in along the line of increasing the efficiency of every pound burned.

Mr. Russell agreed heartily with the suggestion made by Professor Breckenridge that committees be appointed from the Section to work toward the increasing of efficiency. The state administration office has given considerable time to this question. It has almost completed the appointments for the state committee on coal conservation under the chairmanship of Mr. Charles G. Bell.

The Connecticut Section can do much during the coming months. The poor coal dealers have been filling out blanks much more than they have been endorsing checks during the

past two months. The Federal Trade Commission has made a survey in order to get a number of facts from each of the coal dealers. But in our work there is, unfortunately, an absolute necessity for us to come back to these men for almost the same information they have already given to the Commission. This information is buried away in Washington so far as any immediate availability for us is concerned, and it is very much quicker to write to Mr. Pigott at Bridgeport than to write to the Federal Trade Commission for it. I hope it may be possible to unify matters so that there will be no duplication of work.

The coördination of work should be considered very seriously. There are a number of organizations that are interested and are working more or less independently, but we must not have too many committees and too many blanks to do good work. Instead of having a local committee of The American Society of Mechanical Engineers in New Haven and a local committee of the Chamber of Commerce, and possibly a few other local committees, it would be more logical and more efficient to have all the work coördinated.

FUEL CONSERVATION BY THE BUREAU OF MINES

By O. P. HOOD,[1] PITTSBURGH, PA.

Member of the Society

(Abstract of address)

I HAVE been asked to speak about the Bureau of Mines and what it is doing for the conservation of coal. The function of the Bureau is not always understood. We have certain limitations—as far as the fuel of the Bureau of Mines goes, we are limited to the fuels belonging to or for the use of the United States Government. Instead of being a research laboratory for the general public, we must perform that function indirectly. The work of the Bureau of Mines is primarily for Uncle Sam, himself a fuel user. As a user of something like eight million dollars' worth of coal a year in normal times, the Government has a somewhat varied fuel problem.

At the beginning of the war our director asked me what the Bureau could do to adapt itself to the particular situation. Was there a new gospel to be preached? Was there something new and startling that ought to be brought out? My reply was that it was the same old gospel that had to be preached, that it was only a question of different values and different emphasis, but that our problems were exactly the same problems that we had been working on for years.

The Bureau is taking the stand just at present, as every engineer would, that this is not the time to try new experiments, and to look for relief from some new invention, or from some new way of doing things, but we must draw on the well-known and well-tried methods. If each one of us operating a power plant or having anything to do with the fuel problem would do as well as we know how to do without any further instruction, without any more technical information, we could save about ten per cent of our fuel. Perhaps we cannot save that a year from now. People are getting busy; the higher price of coal has forced them to take this gospel more seriously than they have before, and so the problems of the Bureau of Mines are not so essentially different in these war times.

Formerly we were trying to make war on waste, trying to find out the fundamental principles involved in the use of coal and to get people to believe that what we found out was so. The emphasis, however, of the work has been greatly changed. The Bureau believes, or has believed, that educational methods were in the long run the sure methods. There is a growing sentiment which comes to the ears of the Bureau from a great many directions that under the present condition of things some power must be used. It is only a veiled reference to the "big stick." It seems manifestly unjust, if we are to be limited in fuel, that in the same industry two plants, one of which is using its coal inefficiently and the other efficiently, should be treated in exactly the same way and given the same amount of coal. It seems as though there should be some distinction. It would mean going into the plants and finding out the facts. We who have tried to find out facts about a very simple plant know what it costs, know what a tremendous job it is, and how poorly equipped most plants are to give out facts with regard to their coal consumption. The educational processes are of immediate value, at any rate, although they may not be the only means which may have to be applied. These processes must be speeded up; they must be carried on with a magnitude which we have never conceived of before.

General publicity and the creation of an atmosphere which will be favorable to fuel economy, rather than against it, will help in that it will apply to about 20 per cent of the coal mined, and about 20 per cent of the coal is domestic coal. We must influence about twenty million people in order to save a piece of that 20 per cent. Suppose that they could save 10 per cent of it, that means 10 per cent of 20 per cent, which is, roughly, 2 per cent of the whole. To interest that twenty million people means publicity, placards, advertising, and all of the methods the Food Administration employed, for example.

About 63 per cent of the coal mined is used for producing steam. It is used by probably a quarter of a million firemen, and if we could influence and train that quarter of a million men to do their best, we would be doing a valuable thing. In order to reach that quarter of a million firemen who have the coal on their shovels, educational methods on a large scale must be used again. Like all good teaching, this cannot be done by correspondence-school methods, and at long range. It cannot be done by talking about fuel economy as an art. It is a practice. You may read about the fundamental principles on which it is based, but ultimately you must be taught by the hand, and taught at the furnace in just the same way that blacksmithing is taught at the anvil.

The particular work of the Bureau perhaps can be divided into three main headings. There is the purely research work, the attempt to find out things which we did not know before. For that purpose laboratories have been provided. The work has been going on for a good many years, but it is not going on as vigorously today as we could wish. The Bureau is faced with exactly the same conditions that every employer of labor is facing. We are losing our men, we are breaking in new men, and we no sooner get them broken in than they leave us to go to somebody else, and the solution of our problem is thus interfered with. Above all, the Bureau is adapting itself to the new problems which are being presented to it because of the exigencies of the war. A new plant is just being completed in Pittsburgh, and it represents in round numbers about a million dollars. The plant is given up very largely to fuel work, and it is the exponent of the fuel end of the Bureau of Mines.

Another line of work in the Bureau is the purchasing of coal under contract. The Bureau is known to a great many through this activity more than any other, perhaps, in that

[1] Mechanical Engineer, U. S. Bureau of Mines

the Bureau has stood for the purchase of coal on specifications drawn on the basis of B.t.u. It is almost needless to say that under the present conditions the contract has gone glimmering. We no longer think of B.t.u.—we have gracefully retired for the time being, but we will come back stronger than ever when this trouble is over. Fundamentally, the basis is right, but the country is faced with a situation which we have had only once before: namely, we have a sellers' market instead of a buyers' market, and it is only a buyers' market that can talk about B.t.u.

I looked at an analysis the day before yesterday of coal delivered to a Government building. It had 26 per cent ash and 23 per cent moisture. Of course, we realize that the pressure to increase the quantity of coal mined has been severe, and that in the speeding-up process anything black has been called coal. Coals which run around 8 per cent in ash in normal times are now running in the neighborhood of 12 to 15 per cent in ash, and if that extra 5, 6 or 7 per cent ash in the coal applies to all of the coal mined, it means that the apparent increased production in coal is not an increase in coal, but an increase in ash.

Professor Breckenridge's experiments at the St. Louis Exposition seemed to show that in the coals used out there, for every 1 per cent of ash increase in the coal the efficiency of the good coal was reduced about 1½ per cent. There is no absolute figure for that—it will vary anywhere up to 2 or 3 per cent. But suppose there is 7 per cent increase in ash and 10½ per cent decrease in efficiency due to the ash, it can easily be seen what that means to the coal problem.

It can be seen that when one of the great central-station managers made the statement that to produce the same effect his plant was compelled to burn something like 20 per cent more of the stuff they were delivering as coal than they used to burn, it is a serious thing.

Our mining people are beginning to realize this, and they are going to do better. The miner himself has not realized that he was tying up a good many coal cars to haul ash, and that many of his efforts were vain in giving us that stuff.

There is another phase of the Bureau's work. The fuel work of the Bureau was intended to apply to coals belonging to or for the use of the United States Government. We are well aware that if they have any gospel to preach we ought to practise it at home or in our own plants. In the Government plants in general there should be some reasonably high degree of efficiency. There are a number of Government organizations that are very efficient in their steam practice, among them the Navy and Treasury Departments. But there are some organizations of the Government that treat the coal problem just the same as they would the wrapping-paper problem. Coal was cheap, of course it had to be bought, and there was little or no strong organization at the head of the engineering side.

The Bureau of Mines acts as a consulting engineer to the other Government bureaus when they call on us for help in that way. That keeps a number of men busy. For example, over a year ago the Assistant Secretary of the Interior, who had the Bureau of Mines as part of his charge, came to the conclusion that it was not a wise and economical thing to send anthracite coal to Montana, Idaho, Colorado and New Mexico in order to heat the Indian schools; that most people who live out there had to burn local fuels, and he could not see why the Indian schools could not do the same thing. Blanket orders were issued that no anthracite coal was to go west of the Mississippi or north of Kansas. It was proved conclusively that they could not keep a fire over night unless they had anthracite coal. The Bureau had never thought before of trying to contradict this, but now we bought an ordinary hot-blast stove. We had small supplies of coal from all over the world there at the plant, and we proceeded to prove, to ourselves, at any rate, just what kind of a heat curve we could get if we would learn how to use that ordinary hot-blast stove, which we could recommend to an Indian school. I cannot reproduce the curve for you, but you will be interested to know that it is not so very much of a trick to learn how to use those western coals from North Dakota and Wyoming so they can keep a fire just as well as you can in an anthracite burner. Further than that, one can get a temperature curve from the heating surface of the stove that compares very well with anthracite burners. In other words, the Bureau knows that it is just a matter of knowing how.

The Bureau of Mines has to do with the conservation of its own fuel and its own plants for the Government service. Lately there has been a change in accent in the Bureau's work. It was perfectly evident that this was the psychological moment for the propagation of right doctrines; that this was the time when fuel problems must be discussed on a sound physical and economical basis. The air is full of fuel fallacies. As an illustration, I was in Tennessee about a month ago looking over a number of plants there, and I ran across a number of instances where they were following the fallacy that what you need is to get the fire up close to the boiler so it will absorb heat. What was the use of having the boiler way off from the flames? They wanted the flames to hug the boiler!

In all this work there is going to be a large amount of publicity on fuel matters which will help to eliminate the most glaring of the fuel fallacies and will educate the public in the proper facts of the matter.

Just what can the Bureau do in publicity work at this time? It is limited in its funds and it cannot send out literature broadcast. If one wants anything the Bureau has, one must write and ask for it, and can have just one copy. Now it is evident that we cannot carry on a great fuel propaganda under such circumstances.

A number of organizations in Washington believe it is their duty to feature fuel propaganda. It is perfectly natural, perhaps, to expect that the Fuel Administration should do that, and almost equally evident that the Bureau of Mines should do something of the sort. The Geological Survey has been doing something of the sort for years in its particular field, and so has the Chamber of Commerce. The Food Administration is in the fuel game for perfectly good reasons. The Department of Agriculture in its domestic-economy work, which applies directly to the farmer's wife, is considering the question.

In this time of stress the engineering societies ought to do something in this field. The members of these societies have the technical information to give that will set the thing going correctly. It is desirable that in some way the technical information given out shall be consistent. It is not desirable to have anything advocated in one way in one place and another way in some other place. The proper function of the Bureau of Mines at this time is to try to influence the sources of information to publish fuel propaganda; to act as consulting engineers to any of these organizations that we can induce to let us see their manuscripts.

It would be presumptuous for the Bureau of Mines and its limited staff of engineers to perform this function alone. We want the backing and we want to be able to reflect the knowledge and good judgment of the engineers of the country, and so there has been appointed by the Engineering Council

committee from the engineering societies to act as controlling engineers to the Bureau of Mines in helping to guide the technical information which is being disseminated.

DISCUSSION

E. H. Lockwood related some experiments he had made in his laboratory on keeping the doors of the boiler open and seeing what effect this had on the temperature of gases leaving the boiler.

In making some tests with a small boiler, he found that when he closed the grates in the door he got a certain temperature, and when he opened the grates 1/8 in. the thermometer went up 10 to 15 deg., which implied that air coming in the front door made a hotter fire. He opened the grates still wider, and the thermometer began to go down, and it was perfectly plain that in order to get a maximum temperature he had to move the grates in the door open a certain amount.

C. H. Bromley said that the engineers have been preaching and learning how to save coal for many years, and yet they know nothing about burning coal economically! The magnitude of the waste must be brought home now with sufficient force to make us do what we already know how to do. That is the chief problem, and is the reason for wide publicity that will move men to do what they know how to do.

Any man who knows steam-boiler work knows that 20 per cent of the coal burnt under them is wasted. That is a very conservative estimate; we could say more accurately that the avoidable loss in steam production is 35 per cent to 40 per cent. But to be conservative call it 20 per cent, and we have a loss of 45,000,000 tons avoidable waste per annum. Reducing the figure to \$5 a ton, we get an average figure of \$225,000,000 as the money loss per annum.

Another serious loss that occurs in boiler operation is due to the design of the stoker. The stoker has been brought to a very fine state of perfection, but unfortunately no stoker builder has incorporated in his particular stoker the two features necessary to make his machine perfect commercially. The losses due to the combustion in the ash are running now, in the average well-conducted plant, from 20 per cent to 50 per cent. Some stokers have air admission to the dump plate, many of them have not; some have clinker breakers at the clinker or dump grate to break up the clinkers with the air admitted in the fire bed of the stoker. What is wanted is a combination of air orifices or openings that will not clog up, and through which air will be admitted directly to the clinker as it is formed, so that we may burn the carbon up. It was estimated several years ago that Germany was losing approximately 4,000,000 tons of combustible a year due to losses in the ashpit. Our loss in that respect is running very close to 8,500,000 tons of combustible. These are staggering figures, such as we need to stimulate us to action. That 45,000,000 tons, which may be taken as fair waste, means not only money loss, but it means tying up approximately 900,000 fifty-ton cars, a very serious thing.

In the Rainey resolution introduced before Congress in May 1917, it was alleged that over 200,000,000 tons of coal a year are wasted in mining. The eight-hour day granted in May 1916 is responsible for that loss in production. It has amounted in five months in the anthracite industry to over two million tons of coal, and if you look for the anthracite mines on the coal map you can find them. The big problem seems to be at the present time to learn how to burn lower grades of fuel. That must be done through stokers or through better coal. We will have to be moved to action by startling figures so that we may do what we know how to do.

INDUSTRIAL PRODUCTION

A Few of the Elementary Principles of Increasing Production and Decreasing Cost in a Medium-Sized Manufacturing Plant, and at the Same Time Promoting the Welfare of the Employee

By William M. Dollar, Buffalo, N. Y.

Member of the Society

Any scheme of industrial production to be efficient must embody, among others, the following points:

1 The proper purchasing of the proper raw materials
2 The storing of this material so that it will be safe and accessible
3 The rapid and economical transfer of material from the stock room to the factory as needed
4 The progress of material from machine to machine and department to department with a minimum of handling and without congestion
5 The maintenance of a proper system of inspection of work in progress
6 Forms, transfer cards, etc., that require nothing in filling in but the ability to read and make legible figures
7 The handling of time cards first by a man familiar with shop details
8 Remuneration that will bring out the workman's best efforts in regard to quality and quantity of output.

Abstract of paper presented before the Engineering Society of Buffalo, October 31, 1917.

Purchase of Raw Materials

The proper purchasing of the proper raw materials is a commercial matter. It means buying the right quantity at the right time and at the right price, and is largely a matter of judgment which almost amounts to instinct in some men. Regarding quantity, the man who buys should be in close touch with both the sales and the production ends of the business. Buying a large supply of a certain raw material at a low price is of absolutely no advantage if the interest on the money required to make the purchase offsets the saving before the material is used up.

Proper raw materials should be specified by the production or engineering department; many a 2 per cent off has developed into 10 per cent *on* because the goods were not proper for the use to which they were to be put, and the purchasing

agent will usually benefit by taking the advice of the man in the shop, since three times out of four the latter will be right.

Storing Raw Materials

The arrangement of the raw-stock room must be such as to require a minimum of effort both in getting the goods in and passing them out as required. The specific arrangement and construction of the various bins and racks depend on the character and quantity of the goods, and these in turn on the requirements of the business. Only the most general rules can be laid down, as the details of each store room must be worked out to suit the particular case. Accessibility, visibility and cleanliness are important points to keep in mind, and no sacrifice of these should be permitted. A stock room is built but once, but is used every day for years, and the manufacturer can well afford to spend whatever may be necessary to get the best and most economical arrangement and construction.

Equally important is some method by which the stock man can tell at once the exact quantity of a given material on hand, and this, too, with the least labor, clerical or otherwise. One of the easiest ways to accomplish this is by means of a card index consisting of the standard 3-in. by 5-in. cards, with columns for "Date," "In," "Out" and "On Hand," respectively.

The Moving of Material

The rapid and economical transfer of material from the stock room to the factory as needed is emphatically a problem that must be worked out according to the conditions. How the material is handled, whether loose, in bundles, barrels, tote boxes or singly; and whether transported on barrows, trucks, motor trucks, hand trolleys, monorail or traveling crane, depends on the material and the character of the buildings. The less man power used, particularly under present conditions, the better.

The progress of the material from machine to machine and department to department must be effected with a minimum of handling and without congestion. All movements of material should be in one direction, and in as nearly straight lines as possible, from the raw-stock room to the assembling floor, the finished-store room, or the shipping department, whichever its ultimate destination may be. Means should be provided to trace the progress of all material through the factory so that just what progress is being made may be known and the responsibility fixed for any delay.

Inspection of Work in Progress

A proper system of inspection of work in progress must be maintained, as it insures against unnecessary labor on spoiled or defective parts, and also permits steps to be taken at once for the replacement of these parts and avoids delay in the final assembling.

It is not always, or even usually, necessary to maintain an inspection department for this work. Each operator can inspect the work done when the part comes to him, and if it is made to his interest to do so, and to his detriment not to do so, the inspection will be even better done than by the class of help found attached to many inspection departments.

In one instance that comes to mind, where the product was particularly well adapted to piece work, the management hesitated to install it on account of the cost of the inspection. A system of bonuses for the detection of errors and fines for failure to detect them was worked out, with the result that not only was the quantity of the output largely increased but also its quality, while the cost was very materially lowered—and this with all the inspection done by the regular machine hands and assemblers.

Simple Forms Desirable

Nothing beyond the ability to read and make legible figures should be required in filling out forms, transfer cards, etc. Shop men are not bookkeepers, and they usually resent all attempts to make them such. Where conditions are right, some form of time stamp can be used to record the beginning and ending of a given operation; if this method is not practical cards can be so designed that all the workmen has to do is to record the exact start and finish time.

Whatever form these records take they must be used as the foundation not only on which costs are built but also on which the payroll is made up. The workman is not interested in costs but he is vitally interested in the payroll, and if he is obliged to give correct data for compiling costs in order to insure the correct amount in his pay envelope, he will be very careful in filling out his time cards.

Time cards on reaching the office should go first to some one who is familiar with shop details. While the correct number of hours may appear on the card, the time may not be charged to the right job. The man who first handles these cards should be so familiar with the shop that he can not only judge whether the time has been charged to the proper order, but also whether the time so charged is reasonable for the work done. If he is in doubt the card or cards can be at once returned to the shop for correction while the matter is fresh in the minds of the foreman and the workman. This will avoid the recording of incorrect data. Millions have been spent in the shops of this country in the last twenty years by laboriously recording erroneous cost data, because the man who made the record did not know whether the data were correct or not.

While the recording of cost data is a clerical job and properly belongs to the accounting department, the collecting of cost data is an engineering job and must be done by men trained in the practical work of the shop; men who can tell at a glance whether the particular work specified was performed on a given piece, and whether the time alleged to have been so spent is reasonable for the work done.

Erroneous costs, like erroneous drawings, are worse than useless. Not only is the time spent in their preparation wasted, but they lead astray men who without them would usually come out all right by the exercise of their own common sense.

Remuneration Should be Measured by Output

The remuneration received by the workmen must be such as will bring out the best there is in him both as to quantity and quality of his output. I sometimes think that the whole scheme of remunerating human effort is wrong. We pay by the hour, the day, the week, and occasionally by the year. What we are attempting to get is the product. Why pay this man so much for a hour of his time when what you really want is inlet valves, or that man so much for a day of his time when what you want, and all you want from him, is camshafts?

While human nature is as it is, the paying of so much money for so much time will only result in an effort on the part of the employer to get as much as possible for as little money as

possible, and on the part of the employee to get as much money as he can for the smallest possible output. While the workman is taught that the wealth of the world is the result of his labor, he has not been taught that if he shirks his task he detracts just so much from that wealth and consequently from his share of it, so that in the end his shortcomings come back on himself.

What we all need to bring out the best there is in us, is incentive. Under the time-wage system there is no incentive for any man to do more than is sufficient to keep the boss off of his back and hold his job. To those who are troubled with this problem, and with the prevailing idea of making work for as many men as possible, a very potent remedy is an opportunity for the man to add a dollar or two to his weekly earnings in return for a little extra effort. Get away from the idea that there should be a limit to what a man may earn in a given trade. Let the workman understand that you require output. The more pieces he finishes, the lower your cost. If he doubles his output, as he can and will in many cases, your cost per piece is much less, as you have twice the output with practically the same overhead.

How to accomplish this is a matter each manager must settle for himself. There are innumerable schemes under all sorts of names. Whether you use straight piece work, differential piece work, the premium plan, a bonus system or what not, depends on your conditions. While there may be no best system, generally speaking, there is always a best system for each individual plant. There should be no antagonism between employer and employee, their interests should be identical—namely, to add the greatest possible amount to the wealth of the world in order that they may have the greatest possible comfort and enjoyment of it.

To get the best of competitors, make the pay and the working conditions in your plant better than those in any other plant in your line. Get the good men, give them a chance to earn all they can on some equitable plan, and they will do the rest. When you set a price for a piece of work, be sure that the price is just, and then stick to it no matter what the earnings may be. Much of our trouble, and much of the antagonism shown by labor organizations to all forms of piece-rate and profit-sharing payment for labor, is the direct result of improper rates, fixed through lack of knowledge of what can be done, and lack of moral courage on the part of the employer to stand the consequences of a situation brought about by his own ignorance or carelessness.

Planning, Routing, Etc.

So far we have been considering only what is applicable to the small and medium-sized shop, which, in the aggregate, covers a large percentage of the total production. The large shop is in a position to go very much farther along the lines of planning and routing than the small concern can.

There is one best way to do every job in a given shop. There is one best machine for the operation, one best sequence of operations, and one best tool and cutting speed and feed to use. If the material is purchased on rigid specifications, so that it comes uniform, it is perfectly practical to have a planning department which will give to the shop the sequence of operations, the machine to be used for each operation, the cutting tool to be used, and the speed and feed under which it shall be operated.

In the small shop, whether it operates its own foundry or buys its castings from a jobbing foundry, the castings do not usually come of such uniform texture as to make this planning practical. The most feasible plan in a shop of this size is to have the foreman do the routing, and put the entire sequence of operations, together with the character of the tools, speeds and feeds, in his charge. With a competent man having the necessary data in charge of the routing, and material of uniform texture, very satisfactory results can be obtained.

The machine shops of the country owe a deep debt of gratitude to the late Fred W. Taylor and his associates for their work along these lines. Mr. Taylor's paper before the A. S. M. E. on the Art of Cutting Metals is a fitting companion to his former paper on A Differential Piece Rate. The only trouble is that neither of them is applicable in its entirety to any shop, and their introduction into a given shop must be in the hands of men who will select only the part which is practical in that shop. While the modern tool room and the idea of having all tool grinding done in the tool room and not by the individual workmen is the proper thing in the larger shops, it is not practical in a large majority of the small and medium-sized institutions. The solution of the problem in the smaller shop is competent supervision.

It should be the principal duty of the department foreman to see that proper feeds and speeds and proper cutting tools are used on every job. In many shops the foreman is expected to do routine work himself. Any man who is competent to act as foreman, and has charge of more than five or six men, can be of more value to the firm if he spends his entire time in the direction of the others. He should have his finger on every man all the time, and do for his gang just what the planning and routing department would do. If he is the right man for the job he can do this better than any centralized department, because unexpected complications are bound to arise which a competent foreman can straighten out immediately.

Jigs and Fixtures

Just how far any shop can afford to go and how much money it can spend for jigs and fixtures depends on the class and character of its work. On standard manufacturing, proper jigs and fixtures will permit the work to be done with practically unskilled labor, and the modern tendency is to make machine hands and not machinists—the employer has probably gone entirely too far in this direction. With proper jigs and fixtures and a proper tool-room equipment, any man of ordinary intelligence can soon be taught to perform a certain operation or operations so that his output is all that could be accomplished by the most expert machinist. There has been altogether too much of a tendency to consider the operator as simply an attachment to the machine. The idea is that once a green man has been broken in to perform certain operations, he can earn a fair wage on these operations though he be almost worthless on any other job. This is a shortsighted policy and the machine shops today are suffering from it. The workman feels that he is simply a part of the machine. In order to earn a living wage he must stick to the little job which he has been taught to perform, and he resents the treatment. A dissatisfied employee is never profitable, and the sooner the employers wake up to this fact the better for all concerned.

While it is true that this is an age of specialists, is it not also true that before a man can be a specialist on one phase of a given occupation he must first have a good general knowledge of that occupation as a whole? Is it logical to expect to make a specialist on the cylinder-boring machine who has no knowledge of the rest of the machine trade? A man may be an expert in doing a certain thing so long as the conditions are

uniform, but the moment he is confronted with some unusual condition he must fall back on his general knowledge. In machine work, as in every other line, the larger a man's general knowledge of the business, the more expert he will become in some special branch.

The above is a brief statement of the principles upon which successful industrial production is based. Although most of them are self-evident, there is danger of losing sight of them in these days of abnormal conditions. To obviate this danger it might be well to append the following heresies:

a The shortening of the working day has been one of the most serious drawbacks in the effort toward increased production and lower cost. It has been detrimental alike to employer and employee.

b None of us can produce enough in eight hours to enable us to live as we want to live and enjoy the luxuries we have grown to consider necessities.

c American supremacy in manufacturing has come largely through ability to judge what was good enough for the job. Those who waste time and money trying to find whether a given job cost \$9.42 or \$9.47 fail to realize that all costs are only a more or less close approximation, and that the same job can never be duplicated at exactly the same cost.

d Our whole scheme of making machine hands is wrong, and unless we get busy and revive the almost extinct species called "general machinists" we are going to lose out in the race for mechanical supremacy.

e In spite of our boasted ingenuity, our present enemies had us beaten mechanically because they trained men for the job for which they were best fitted. Unless they are all killed off or we change our ways they will do it again. You cannot make a superintendent out of a man who has only the capacity of a gang boss.

f We must get away from the fads now in vogue, and must employ men to fit the job.

CORRESPONDENCE

Contributions to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

The Crippled Soldier

To the Editor:

"Though far apart, we're one at heart,
In the homelands of the free."

It is for the second reason that I wish I could have been present to listen to and discuss in person the interesting paper on the crippled soldier read by any old friend, Major Frank B. Gilbreth, E. R. C.

For the past 1000 days or more we in England have suffered in spirit with the maimed heroes back from the front, and have had daily ocular proof of the urgent necessity of supporting any movement to make them, where possible, healthy, happy and productive citizens again.

Much has been done, but plenty of scope still exists for the engineer, the scientist and others to exercise their talents in devising improved methods and channels to assist the ever-growing army of sufferers, whether victims of the war or of industry, and I hope that all classes of society in the allied countries will enter heart and soul into the campaign.

In Europe, where scientific management and motion study have not yet made the headway we could wish, its teachings being unknown to the majority, greater difficulty in establishing Major Gilbreth's recommendations will be encountered than in the U. S. A., for you have already introduced and are profiting by accurate measurement.

I feel sure, however, that when you have shown what can be done, we shall be glad to avail ourselves of your practical experience and achievements. To instance the prejudice and lack of imagination existing here, I quote from a reply written recently by a Government department whose attention had been drawn to some of Major Gilbreth's instruments of precision:

"Although these matters have obviously considerable interest in appropriate spheres, it is not thought that such apparatus as is described presents sufficient advantages and utility from the point of view of possible assistance to crippled soldiers as to justify any further action being taken in the matter."

The pity of it!

Nevertheless we must not be discouraged, but must keep on hammering away until the rust is dispersed and the true metal appears. We know it is there, and that sooner or later it must be reached, and, as a result, the lot of all cripples made more contented and easier.

James F. Butterworth.

London, England.

Cooling of Water

To the Editor:

The curves of cooling efficiency in the paper on The Cooling of Water for Power Plant Purposes, presented by Prof. C. C. Thomas at the Annual Meeting, are of great use in predetermining the size of pond for a given duty. It is questionable, however, if the expression connecting efficiency and temperatures: namely, $E = (T_1 - T_2)/(T_1 - T_w)$, is applicable outside of certain narrow limits of wet-bulb temperatures T_w. Some readings taken recently on a Thomas nozzle in cold weather were as follows:

Temperature of hot water, deg. fahr.	115	91
Temperature of cold water, deg. fahr	85	68
Temperature of air, deg. fahr.	31	26
Pressure at nozzle, inches of mercury.	8	10
Efficiency, per cent.	36	35
Character of spray	Fine	Fine

In calculating the efficiency the wet-bulb temperature was assumed equal to the dry-bulb. For the same conditions the chart of Fig. 9 indicates efficiencies from 55 to 65 per cent. In other words, if this chart were used to predict cooling for winter conditions, temperatures of sprayed water would be indicated much lower than those actually obtainable.

This phenomenon can be explained by the fact that cooling by evaporation goes on less readily in cold weather than in

warm. Thus, suppose the air rising through the spray is heated 25 deg. fahr. Then the volume of air required to take up 1 lb. of moisture or "absorb" about 1000 B.t.u. will be as follows:

Air required, cu. ft.	2500	1800	1300	1000	750	600	500
Wet-bulb temp., deg. fahr	30	40	50	60	70	80	90

In warm weather only one-third to one-fifth as much air is needed to take up the same heat.

This decrease in relative efficiency of cooling was noted some time ago in the analysis of cooling-tower performances. For this purpose a coefficient of heat dissipation was used, equal to the heat units per hour per degree difference of temperature between mean water temperature and wet-bulb temperature per square foot of air-flow area. For the two types of towers the following values were found:

Wet-bulb temperature, deg. fahr.	Coefficient of Heat Dissipation	
	for forced-draft towers	for natural- or chimney-draft towers
−10	500	
+30	700	
50	1000	...
60	1250	340
70	1500	...
80	1800	440

In applying empirical formulæ for spray cooling the influence of the season of the year should not be overlooked. The same caution applies when making acceptance tests of cooling ponds or towers.

Broader Fields of Usefulness for the A.S.M.E. Sections

TO THE EDITOR:

At this time, when the spirit of service is in the air, loyal Americans are looking for opportunities to make their experience and influence felt. It, therefore, seems to come with special fitness that the sectional activities of the A.S.M.E. are being stimulated and encouraged by the adoption of new By-Laws providing for a more comprehensive and progressive plan for the future.

This has been well pointed out by Louis C. Marburg in his address at the last annual meeting in New York, which was published in the March number of THE JOURNAL.

The opportunity afforded by the revised By-Laws for each section to suit its activities to the local needs gives freedom of action which can be of great value in arranging the best program for each locality.

Coöperation between local engineering interests can also be cultivated to advantage through the Sections, and in such matters as standardization, which in most cases affect more than one line of engineering, greater uniformity of action and results more far-reaching in their scope can be attained.

Such coöperation also is of special value in taking up community matters of an engineering character, which, as Mr. Marburg says, should be more and more a feature of the work of engineering organizations, in order that they may hold the place which is due them on account of the importance of their work.

All these reasons, which apply strongly in times of peace, are much accentuated now that we are in the midst of the critical situations arising from the Great War.

LUTHER D. BURLINGAME.

Providence, R. I.

HOW TO JOIN THE ARMY ENGINEERS

During the past three years the best engineering skill of France and Great Britain has been matched against that of the Central Powers, and the same skill is urgently required in the United States Army. Enlistments of experienced technical men in our army, however, are below requirements. While this deficiency is undoubtedly due in part to the high salaries which American firms are paying their employees, it probably is also due to the lack of proper information concerning the engineering branch of the service. Few civilians know that it is possible for them to perform in the Engineering Corps almost exactly the same kind of work in which they are at present engaged.

It is more important to have the right man in the right place in our army, where lives of men are at stake than it is in any business enterprise. The First Replacement Regiment of Engineers was organized at Washington Barracks, D. C., on December 14, 1917, with the express idea of accomplishing this end. This regiment has not only the responsibility of finding men to fill up depleted ranks but it must also fit the men thus obtained to step into the work of trained, efficient and disciplined soldiers.

The preliminary work of the recruit is first a thorough training in military drill, for the engineer soldier must be prepared to lay down his shovel and take up his rifle at any time. Infantry drills gradually give way to engineer work and more specific technical training. The engineer soldiers must know how to tie all the important kinds of knots and lashings, to build spar and truss bridges, to construct revetments, dig trenches, place wire entanglements, construct machine-gun emplacements, build pontoon bridges and to construct roads. They must also know the methods of demolition, sapping and mining. Specialized training in lithography, zincography, surveying, mapping, photography, carpentry, blacksmithing, electricity and machinery will also be given to all of those who are qualified for further training in any of these branches.

The Replacement Regiment will be called upon to furnish men for the following regiments, battalions or companies: Camouflage; Crane Operating and Maintenance; Depot Service; Electrical and Mechanical; Forestry (Saw Mill); Forestry (Auxiliary Road, Camp and Bridge); Gas and Flame Service; General Construction; Mining; Quarrying, Sapper; Searchlight; Supply and Shop; Surveying, Ranging and Map Reproduction; Water Supply.

Every male citizen in the United States who is physically fit, and between the ages of 18 and 21, and 31 and 40, is eligible to join the regiment by voluntary enlistment.

To be assured of assignment, the applicant for enlistment, should write for an application blank to the Commanding Officer, 1st Replacement Regiment Engineers, Room 107, Headquarters Building, Post of Washington Barracks, D. C. If the blank shows the man to be eligible, an enlistment card is filled out and sent to the Recruiting Officer nearest to the applicant's place of residence, with instructions to enlist the man for service in this Regiment. Transportation and meals will be furnished by the Recruiting Officer and the man will be instructed to report at the Post for duty.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 175, 185 and 186, as formulated at the meeting of February 20, and approved by the Council on March 15, 1918. In this report, as previously, the names of inquirers have been omitted.

CASE NO. 175

Inquiry: How is the maximum allowable working pressure to be calculated for the radial section of the outside fire-box plate of locomotive boilers where stayed to the firebox sheet?

Reply: There appears to be no rule in the Boiler Code that makes allowance for the supporting power of such curved stayed surfaces. It has been proposed to revise Par. 212 of the Code to read as follows:

212*a* The maximum allowable working pressure for any curved stayed surface subject to internal pressure shall be obtained by the two following methods, and the minimum value obtained shall be used:

First, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the holes for the stays. To this pressure there shall be added the pressure secured by the formula for braced and stayed surfaces given in Par. 199 using 70 for the value of C.

Second, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the holes for the stays. To this pressure there shall be added the pressure corresponding to the strength of the stays for the stresses given in Table 4, each stay being assumed to resist the steam pressure acting on the full area of the external surface supported by the stay.

b The maximum allowable working pressure for a stayed wrapper sheet of a locomotive type boiler shall be determined by the two methods given above and by the method which follows and the minimum value obtained shall be used:

$$P = \frac{11{,}000t \times E}{R - s\Sigma \sin \alpha}$$

in which

α = Angle any crown stay makes with vertical axis of boiler

$\Sigma \sin \alpha$ = Summated value of sin α for all crown stays considered in one transverse plane and on one side of vertical axis of boiler

s = Transverse spacing (in.) of crown stays in crown sheet

E = Minimum efficiency of wrapper sheet through joints or stay holes

t = Thickness of wrapper sheet (in.)

R = Radius of wrapper sheet (in.)

P = Working pressure of boiler, lb. per sq. in.

11,000 = Allowable stress, lb. per sq. in.

c An internal cylindrical furnace which requires staying shall be stayed as a flat surface as indicated in Table 3, except that the pitch may be increased to p_1 as provided in the following formula:

$$p_1 = p\sqrt{\frac{PR}{PR - 250t}}$$

in which p, P, R, and t are the same as in Par. 199.

CASE NO. 185

Inquiry: Where horizontal fire-tube boilers are so set that the lower part of the shell is not exposed to the fire or products of combustion, is it allowable to dispense with through braces as required by Par. 218 of the Boiler Code, and employ tubes at the sides of the manhole in place of such braces?

Reply: In horizontal fire-tube boilers which are set so that the fire or products of combustion do not come in contact with the lower part of the shell, tubes may be used instead of braces at the sides of the manhole as outlined.

CASE NO. 186

Inquiry: What should be the radius of the fillets formed by the flanging of the sheets of domes to drum connections for riveting to the shells of boilers? There does not seem to be any rule in the Boiler Code covering this detail of construction.

Reply: It is the opinion of the Boiler Code Committee that the flanges should be formed with a corner radius, measured on the inside, of at least twice the thickness of the plate for plates 1 in. thick or less, and at least three times the thickness of the plate for plates over 1 in. in thickness.

REVISION OF BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in THE JOURNAL with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes before the Rules are brought to the final form and presented to the Council for approval. This has been done, and the revisions were presented in the March issue of THE JOURNAL, pp. 234-247, in the form finally proposed for submission to the Council, except as they may be modified by editing without change of sense. Discussions should be mailed to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y., and they will be presented and acted on by the Boiler Code Committee.

Since the publication of the March issue of THE JOURNAL, however, certain typographical errors have been discovered in the revisions there presented, and corrections of these are published below, together with the modification of Par. 21, which it was stated in the March issue was in the hands of a special Sub-Committee of the Boiler Code Committee on Tube Sizes. The Sub-Committee has now completed its research and investigation, and its recommendation that Par. 21 be replaced by a table of maximum allowable working pressures

for different diameters and gages of tubes has been approved by the Boiler Code Committee.

286 A safety valve over 3-in. size, used for pressures greater than 15 lb. per sq. in. gage, shall have a flanged inlet connection.

A number of fundamental laws governing the properties of wood, such as those covering the relations between strength and specific gravity, and between strength and moisture content, are laid down in Bulletin No. 556 just issued by the Department of Agriculture, entitled Mechanical Properties of Woods Grown in the United States, by J. A. Newlin and Thomas R. C. Wilson. In this publication are presented the results of about 130,000 strength tests, probably the largest single series ever run on one material, made by the Forest Products Laboratory of the Forest Service on 126 species of American woods. The laws derived from the tests cover the general relations existing between mechanical and physical properties of each species, and also the general relations existing between these properties irrespective of species.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

IT will hearten the membership, I know, to learn more in detail of the extraordinary service being rendered by this Society through its Engineering Resources Committee.

A classification sheet was sent out to every member of the Society and nearly every member has responded. Based on the replies, the following are the statistics secured:

Common-school education	8600
High-school education	8280
Graduate mechanical engineers	5550
Graduate electrical engineers	575
Graduate civil engineers	140
Graduate mining engineers	21
Other degrees	920
Speak and read French	2510
" " " German	2290
" " " Spanish	600
" " " Russian	64
" " " Italian	70
" " " Japanese	31
" " " other languages	490
Traveled extensively in Europe	1360
" " " South America	225

Works manager	1185

To date nearly 3000 names have been furnished to the several Bureaus of the Government and to the industries generally since the beginning of the war. Notwithstanding that this is obviously a "win the war" activity, our lists are invaluable for the industries whether or not those industries may be engaged in war activities. We probably have the most complete list in existence of specialists, together with their attainments, experience, etc.

Any member not having filled out the classification sheet should immediately write and ask that such a sheet be furnished him, as it is of the highest importance that every man should make his services available to his country. Even if one is not free to give all of his time, if he can give a portion of his time or can make special investigation in his own establishment, all of such services can be made available.

The members of the Committee, George J. Foran, Chair-

man, Fred H. Colvin, Henry C. Meyer, Jr., W. Herman Greul, and formerly J. H. Barr and A. D. Blake, until they were transferred to Washington and absorbed in the service of the United States, give personal attention to requests. The Secretary and his staff supplement the work of the Committee, so that the Government and the industries generally get not only the benefit of a list of specialists, but the assistance of the Committee and the staff of the Society in an attempt to select the men best fitted for the particular work. An excess of the number required is always recommended, so that the Government has the opportunity to make a selection from among those given.

Please help by making sure that your name is on this roll, and still further by suggesting the names of any men especially competent in any realm of engineering who are not now members and whose availability for service should be recorded, and we shall be pleased to send them classification blanks, to be filed separately.

CALVIN W. RICE,
Secretary.

COUNCIL NOTES[1]

A MEETING of the Council was held on Friday, February 15, 1918, in the rooms of the Society. The following members were present: Charles T. Main, *President;* R. M. Dixon, *Chairman Finance Committee;* R. H. Fernald, George J. Foran, representing the *Publication Committee;* F. A. Geier, W. F. M. Goss, Ira N. Hollis, John Hunter, F. R. Hutton, D. S. Jacobus, H. de B. Parsons, Charles T. Plunkett, D. Robert Yarnall, Wm. H. Wiley, *Treasurer;* Henry Hess, *Chairman Standardization Committee,* and Calvin W. Rice, *Secretary.*

Nominating Committee. The President announced that the Sections had selected the following names, and that he had had great pleasure in making them his appointments for the Nominating Committee for officers for 1918: L. P. Breckenridge, William P. Caine, Thomas E. Durban, C. F. Hirshfeld and George R. Wadleigh. A full announcement regarding these appointments was published in the March issue of THE JOURNAL.

Power Test Code. In accordance with the vote at the last Council meeting, the President presented a set of rules for the guidance of the Power Test Code Committee and its sub-committees and advisory board, prepared in collaboration with George H. Barrus, Chairman of the Committee.

Engineering Council. It was voted to approve the appointment by the President of Charles Whiting Baker, George J. Foran and D. S. Jacobus to represent this Society on a special Conference Committee of the Engineering Council to consider and report back to the Engineering Council rules for the admission of associate societies.

Society for the Promotion of Industrial Education. In response to the invitation from the Society for the Promotion of Industrial Education, John W. Lieb and R. H. Fernald were appointed honorary vice-presidents to represent the Society at its Philadelphia meeting, February 21 to 23.

National Security League. A. D. Bailey, William B. Jackson and Arthur L. Rice were appointed honorary vice-presidents to represent the Society in response to the invitation of the National Security League at their meeting in Chicago, February 21 to 23.

War Activities. It was voted that all committees of the Society having to do with war activities be requested to report each month to the Council.

Library Committee. The Council approved in principle recommendations of the Library Committee that the title of the Library of the Society be transferred to the United Engineering Society. The matter was referred back to the Library Committee to obtain advice of counsel.

Sections Committee. D. Robert Yarnall, Chairman of the Committee on Local Sections, presented a report of recommended procedure for the election of a Nominating Committee, and it was voted to transmit copies of the report to the Committee on Constitution and By-Laws and to every member of the Council for consideration, and report at the next meeting.

Meetings Committee. This committee reported that in consultation with the Worcester Local Committee, the date for the 1918 Spring Meeting of the Society at Worcester, Mass., had been set for June 4 to 7.

War Department, Ordnance. The Secretary reported the receipt of a letter of thanks from the Chief of Ordnance for the coöperation of the Society in securing ordnance officers.

Screw Thread Tolerances. Acting upon a communication of January 23 from the various tap manufacturers, requesting permission to scrutinize that part of the report of the Committee on Tolerances in Screw Thread Fits relating to taps, the report was referred back to the Committee to carry out this request and, should the manufacturers ask for any revision, to give their request due consideration and again submit the report, revised, if necessary, to the Council.

Machine-Shop Practice Committee. The Secretary reported that another way in which the Society was helping in war activities was through the Sub-Committee on Machine Shop Practice, and that in response to a request from the Director of Division Trade Tests, Committee on Classification of Personnel of the Provost Marshal, our committee had met and was assisting the Provost Marshal in the preparation of statements of the requisites in the various machine trades.

Sub-Committee on Protection of Industrial Workers. The following reports from this committee were received and ordered printed in TRANSACTIONS as part of the proceedings of the year 1917:

1 Code of Safety Standards for Elevators
2 Code of Safety Standards for Woodworking Machinery
3 Code of Safety Standards for Industrial Ladders
4 Code of Safety Standards for Power-Transmission Machinery.

Nos. 1 and 2 were presented at the Spring Meeting, 1917, and Nos. 3 and 4 at the Annual Meeting, 1917.

Coöperation and Organization. On account of the assignment to war work of the members of the Committee on Coöperation and Organization, it was voted that this committee be discharged with thanks and the work be referred to the Sub-Committee on Machine Shop Practice.

Electric Welding Society. A request of the Electric Welding Society asking affiliation with this Society was referred to the Boiler Code Committee with instructions to appoint a subcommittee on Electric Welding of the Boiler Code Committee.

Boiler Code Committee. It was voted that the present Committee on Boiler Code be reappointed as the Committee for 1918.

Adjournment was taken to reconvene on March 15, 1918.

CALVIN W. RICE,
Secretary.

[1] The March JOURNAL went to press before the February Meeting.

United Engineering Society

Extracts from President's Annual Report

FOR the year 1917 the noteworthy occurrences are the creation of the Engineering Council, the completion of the addition to the Engineering Societies Building and the occupation by the American Society of Civil Engineers of the space thus provided for it, the addition of 67,000 volumes from the Civil Engineers' Library to the Engineering Societies Library, the election as Director of the Library of Harrison W. Craver, formerly of the Carnegie Library of Pittsburgh, and the election of Alfred Douglas Flinn to serve the United Engineering Society, the Engineering Foundation and Engineering Council jointly as their secretary, with offices in the Engineering Societies Building.

The Engineering Council held its first meeting on June 27, elected Ira N. Hollis chairman and Calvert Townley secretary, and during the year appointed the following committees: Executive, Rules, Finance, Public Affairs, American Engineering Service, and War Committee of Technical Societies. Good work has been done, but the Council has not perfected its organization, and it was not until the close of the year that a definite financial arrangement was made; an appropriation of $16,000 was requested and granted for the term ending October 31, 1918, to be assessed equally upon the four Founder Societies.

In October, the three new stories of the Engineering Societies Building were so far completed that the American Society of Civil Engineers could move into its new quarters, and were wholly completed before the end of the year. The total cost was $302,027.01, the increase over the estimate being caused by the War. The American Society of Civil Engineers held its annual meetings in the building in January, 1917, and its first regular semi-monthly meeting on November 21, since which latter date all the meetings of this society have been held in the new quarters.

On December 7, at a meeting in the Auditorium, the three original Founder Societies and United Engineering Society tendered a welcome to the American Society of Civil Engineers. [An account of this meeting has already b en published in The Journal.]

In February, 67,000 books and pamphlets from the Civil Engineers' Library, which were not duplicates of books and pamphlets previously in the Engineering Societies Library, were removed from the 57th Street house of the Civil Engineers to the Engineering Societies Building and placed upon stacks in the same arrangement as in the old building. Ownership of this collection of books has been offered by the American Society of Civil Engineers to the United Engineering Society. Similar action has been taken by the American Institute of Mining Engineers and is expected to be taken by the other Founder Societies. Mr Craver began his duties as Director of the Library on April 2.

September 20, 1917, terminated the year for which the Engineering Foundation had appropriated its income and devoted the services of its secretary, Dr. Cary T. Hutchinson, to the establishing of the National Research Council. The Council was organized on September 19, 1916, and during the year accomplished much useful scientific work in coöperation with the Government. Among these achievements may be mentioned advance in the art of submarine detection, location of aircraft by sound, telephoning between airplanes, protection of balloons from ignition by static charges, progress in gas-warfare problems, and the production of optical glass. The National Research Council now acts as the Department of Science and Research of the Council of National Defense. Further interesting details of the work of establishing the National Research Council are contained in a report dated September 20, 1917, which was published in the Proceedings of the Founder Societies. The National Research Council is now wholly supported by the Government and has offices in Washington.

Completion of the first and major portion of the Catskill Mountain water-supply system for New York City was celebrated by the United Engineering Society and the four Founder Societies by a special meeting held in the Auditorium, November 14, attended by about 1100 persons. [An account has already been published in The Journal.]

During the year the by-laws of United Engineering Society were amended to create the office of Director of the Library and to provide for the creation of the Engineering Council, the former amendment being made in February and the latter in June.

During the summer, the Tax Department of the City of New York placed the Engineering Societies Building on the list of taxable property and referred the claim of United Engineering Society for exemption to the Corporation Counsel. Later it was decided that six of the associate societies in the building did not satisfy the exemption requirements found in Subdivision 7 of Section 4 of the Tax Law, and that consequently the portions of the building occupied by them would be subject to taxation.

At this date the membership of the four Founder Societies is 33,100 and of the associated societies 25,154, so that a total of 58,254 engineers now have headquarters in the Engineering Societies Building.

The real estate now owned by United Engineering Society is valued at $1,947,171.16.

The income of the Society during 1917 was	$55,854.72	
Expenditures totaled	53,791.87	
Gain for the year	2,062.85	
Surplus at the close of 1916	6,053.25	
Total		$8,116.10

Funds for the benefit of the Engineering Societies Library were obtained during 1917 from the following sources:

American Society of Civil Engineers	$4,000.00
American Institute of Mining Engineers	4,000.00
American Society of Mechanical Engineers	4,000.00
American Institute of Electrical Engineers	4,000.00
United Engineering Society	262.35
Income from endowment fund	5,760.42
Gross income from searches	6,556.19
Sales and income	29.40
Total income	$28,605.36

Library expenses were as follows:

Salaries	$16,961.16
Books purchased	1,614.47
Binding	1,393.35
Supplies	1,299.89
Moving Civil Engineers' Library	381.50
Searches, salaries, and miscellaneous	6,759.54
Total	$28,605.36

Funds held by the United Engineering Society were of the following amounts at the end of the fiscal year 1917:

Library endowment fund	$102,559.70
Engineering Foundation fund	203,374.80
General reserve fund	10,000.00
Depreciation and renewal fund	75,037.41
Surplus	8,116.10
Total	$399,088.01

In the report of the Treasurer are many interesting details about the Society's finances, and in the report of the Library Board a full statement of its activities, showing the importance of the work being done.

Mr. Calvin W. Rice resigned as Secretary of the United Engineering Society to take effect at the end of December, and the Society is indebted to him for a year of gratuitous service.

To Mr. Joseph Struthers who has been Treasurer for nine years, and to the members of the Building Committee, especially its Chairman, H. H. Barnes, Jr., the Trustees would express hearty thanks for valuable services.

CHARLES F. RAND,
President, United Engineering Society.

New Officers of Engineering Council

At the first annual meeting of the Engineering Council, on February 21, J. Parke Channing was elected chairman; Harold W. Buck, first vice-chairman; George F. Swain, second vice-chairman; and Alfred D. Flinn, secretary. The following committees were appointed:

Executive Committee: The chairman, the two vice-chairmen, and David S. Jacobus, Calvert Townley, George J. Foran.

Finance Committee: E. Wilbur Rice, Jr., chairman; Charles F. Loweth, Sydney J. Jennings, David S. Jacobus.

Rules Committee: J. Parke Channing, chairman; Clemens Herschel, Nathaniel A. Carle, Irving E. Moultrop.

Public Affairs Committee: Charles Whiting Baker, chairman; George F. Swain, Benjamin B. Thayer, E. W. Rice, Jr., Charles E. Skinner.

American Engineering Service: George J. Foran, chairman; George C. Stone, Alfred D. Flinn, Dr. Addams S. McAllister, Edward B. Sturgis, secretary.

War Committee of Technical Societies: D. W. Brunton, chairman; Arthur H. Storrs, secretary; James M. Boyle, Nelson P. Lewis (American Society of Civil Engineers), Edmund B. Kirby (American Institute of Mining Engineers), A. A. Greene, Jr., R. N. Inglis (American Society of Mechanical Engineers), Harold W. Buck, Dr. Addams S. McAllister (American Institute of Electrical Engineers), Dana D. Barnum, E. C. Uhlig (American Gas Institute), Joseph Bijur, Dr. Chas. A. Doremus (American Electrochemical Society), Louis B. Marks, Preston S. Millar (Illuminating Engineering Society), Christopher R. Corning, George C. Stone (Mining and Metallurgical Society of America), Henry Torrance, F. E. Matthews, (American Society of Refrigerating Engineers).

Fuel Conservation Committee: L. P. Breckenridge, chairman; Ozni P. Hood, secretary; Robert H. Fernald, Charles R. Richards, Charles L. Edgar, Carl Scholz, David Moffat Myers, Edwin Ludlow, Harold W. Buck.

J. PARKE CHANNING

J. Parke Channing, the newly elected chairman, was born in New York City and was graduated from Columbia University with the degrees of Engineer of Mines and Master of Science. After graduation he was first engaged in mining in the Lake Superior iron and copper region, and later in Montana, Utah and Tennessee. In 1900 he developed and equipped the Tennessee Copper Company, and a few years later built one of the largest sulphuric-acid plants in the world to utilize the waste gases from its copper furnaces. In 1907 he discovered and developed the Miami copper mine in Arizona, now producing copper at the rate of 60,000,000 lb. per year.

For three years Mr. Channing was president of the Mining and Metallurgical Society of America, and is now its vice-president. He was one of the founders of the Lake Superior Mining Institute and is one of its past-presidents. He was directly responsible for the founding of the Michigan College of Mines. He is a member of the American Institute of Mining Engineers and one of its former vice-presidents. He is also a member of the Institute of Mining and Metallurgy, England. He is vice-president of the Miami Copper Company and of the General Development Company.

Dr. Ira N. Hollis, the retiring chairman of the Engineering Council, has given untiring effort to the first year of the Council's existence, with its many problems of organization and the great number and variety of suggestions for usefulness to the Government in connection with the war. In spite of his residence in Worcester, Mass., and his many duties there, he attended all Council meetings and meetings of the executive committee in New York, and made frequent trips to Washington. His enthusiastic devotion to the Engineering Council during the year that he was also President of The American Society of Mechanical Engineers made large demands upon time already heavily mortgaged by his duties as president of the Worcester Polytechnic Institute and by related activities.

SPRING MEETING

WORCESTER, MASS., JUNE 4-7

THE program for the Spring Meeting, an outline of which appears on this page, provides a much-needed opportunity for the engineers of the country to get away from their strenuous war duties, take counsel with each other, and obtain a broader vision of the great undertakings for which they are now responsible. America must supply home demands during the war, without sacrificing the war demands, with firms of other countries; but under the stress of the present moment it is necessary to pool our knowledge and to coördinate our work, a result which can be best attained by getting together for an interchange of ideas. It is this function which it is expected that the Spring Meeting will fulfill, and to this end the Committee on Meetings has arranged for a discussion of topics of great industrial importance.

TENTATIVE PROGRAM

TUESDAY, JUNE 4

Afternoon: (Hotel Bancroft)

Registering of Members and Guests at Society Headquarters

Meeting of Research Committee and Flow Meters Sub-Committee

Evening: (Hotel Bancroft)

Addresses of Welcome by Mayor Pehr G. Holmes, Past-President Ira N. Hollis, and R. Sanford Riley, President Worcester Chamber of Commerce

Reception and Dance following the addresses

WEDNESDAY, JUNE 5

NEW ENGLAND DAY

Morning: (Worcester Polytechnic Institute)

Business Meeting

First New England Session:

Papers and addresses contributed by the New England Sections of the A. S. M. E. and the Providence Engineering Society. The topics listed below will be begun at this session and continued in the afternoon

The Growth of an Industrial City, Hon. Charles G. Washburn

The Small Industry and Democracy, Dr. George H. Haynes

The Textile Industry in Relation to the War, J. E. Rousmaniere

Other subjects to be presented are: Changing a Non-essential Industry to Munition Manufacturing; Organizing a Compact Community for the Manufacture of War Material; Fire Protection for Industrial Plants; The Boston Plan for Vocational Training of Enlisted Men; Aeroplane Manufacture; Constructional and Manufacturing Problems in Building Destroyers

Sections Luncheon and Conference

Afternoon: (Hotel Bancroft)

Second New England Session:

General Session with technical papers

Industrial Safety and Workmen's Compensation Session

Tea at Tatnuck Country Club

Evening: (Hotel Bancroft)

General War Session. The general theme of this evening session will be: How the Engineering Societies Can Assist in the Procurement Program of the Government. Some major topics to be discussed are: Ordnance and Ships for the Navy Department; Munitions for the Army; Aircraft Material; Merchant Ships

THURSDAY, JUNE 6

Morning: (Worcester Polytechnic Institute)

General Session with technical papers

Fuel Session (a list of topics follows the program)

Public Relations Session

Afternoon: (Norton Company's Plant)

Luncheon

Paper on Housing Problems

Inspection of the Norton Company's community housing and garden projects

Evening: (Worcester Country Club)

Dinner

Illustrated Lecture: Harvard's Contribution to Astronomy, Dr. S. I. Bailey, of Harvard Observatory

FRIDAY, JUNE 7

Morning:

Automobile Trip to Camp Devens, via Clinton Dam

Lunch at Camp Devens

Afternoon:

Auto Trip to Concord, Lexington and return via the Wayside Inn

and she must do this with a gradually diminishing supply of labor. Mass production is required on an enormous scale and machine production must be carried into fields where hand work has formerly prevailed. There must be greater efficiency and economy, greater foresight, more extended research and more careful planning.

In normal times Americans have generally accomplished their results individually in competition with one another and

New England is probably the largest center of munitions production in the country. Accordingly, a New England Day has been arranged, when the engineers connected with the manufacturing plants of that section engaged upon war work, are asked to present their problems for discussion and to contribute any data which will be of value to others. On the evening of the same day, representatives of several of the governmental departments engaged in the procurement of supplies

for the Army and Navy will give addresses. Another session will be for the discussion of questions incident to Fuel Economy, as outlined in the article which follows, when all who have had to give serious consideration to improved methods for fuel burning during the past winter are asked to contribute the results of their experience for the benefit of the Fuel Administration.

Vocational training for enlisted men, and housing problems incident to war conditions are to be discussed and one session will be devoted to municipal problems of the engineer in war times. There will also be a careful selection of miscellaneous technical papers, so that there may be put on record in the Society Transactions the results of engineering research, in accordance with the usual custom of the Society in conducting its publications.

The Local Sections of New England and the Providence Engineering Society are actively coöperating with the Committee on Meetings in the preparations for the convention. During the first three days simultaneous sessions will be held in order to complete the professional business by Thursday night. This will leave Friday free for a trip by automobile to the cantonment at Camp Devens, Mass., and for a visit to the historic places of Concord and Lexington. Probably most of those who will be present fully appreciate that this part of New England is one of the most beautiful sections of the country for outdoor life, and this trip on Friday, as well as the other social features, has been arranged with a view to the enjoyment of outdoor pleasures to the fullest extent.

FUEL SESSION

SPRING MEETING, WORCESTER, MASS., JUNE 6

On Thursday morning, June 6, there will be a session of the Spring Meeting at the Worcester Polytechnic Institute for five-minute presentations of data relating to fuel economy. This session has been planned by the Fuel Conservation Committee of the Engineering Council to assist the United States Fuel Administrator in his nation-wide campaign for fuel economy. The topics upon which discussion is solicited are listed below and all members of the Society, or others, who have studied the problems incident to the adverse fuel conditions of the past winter are invited to give the results of their experience in the form of brief written communications of from 100 to 1000 words each. In so far as possible, these will be presented at the time of the meeting and later collated for publication and for transmission to Dr. Garfield's department at Washington. Contributions to this session should be mailed to the Secretary of the Society, 29 West 39th Street, New York, not later than May 1.

1 WHAT ARE THE ECONOMIC EFFECTS OF IMPURITIES IN COAL?
Incombustible in fuel has a detrimental effect upon furnace operation out of all proportion to the percentage of refuse contained. It has been claimed that when coal contains 40 per cent of refuse it becomes valueless as fuel. Recent conditions have afforded opportunities for interesting observations in this connection. What has been your experience?

2 TO WHAT EXTENT IS FUEL OIL LIKELY TO BE USED AS A SUBSTITUTE FOR COAL?
Information is desired as to present use, advantage found, probable available supply, etc.

3 HOW CAN SOFT COAL BE BURNED WITHOUT SMOKE IN MARINE BOILERS?
The avoidance of smoke would decrease the radius of visibility of our ocean carriers by many miles and greatly reduce their liability to attack by submarines. If efficiency is improved incidentally it means much more than the mere coal saving.

4 WHAT ARE THE POSSIBILITIES IN THE DIRECTION OF THE UTILIZATION OF ANTHRACITE WASTES?
What success have you had in burning anthracite slack or culm? Do you mix it with soft coal, and in what proportions? What sort of grate do you use and what is your practice with regard to thickness of fire, draft, rate of combustion? Can the mixture be burned in a stoker?

5 WHAT INSTRUMENTS ARE USEFUL AND DESIRABLE IN THE BOILER ROOM AS AIDS IN SAVING COAL?
What class of equipment has been of the most value to you and how?

6 WHAT IS ESSENTIAL TO THE ECONOMICAL OPERATION OF HAND-FIRED BOILER FURNACES WHEN USING SOFT COAL?
Helpful hints as to firing methods, front or side; frequency of firing; management of dampers; cleaning; etc.

7 TO WHAT KINDS OF PLANTS AND COALS ARE THE DIFFERENT TYPES OF MECHANICAL STOKERS RESPECTIVELY ADAPTED, AND WHAT IS THE LIMITING FACTOR TO THEIR USE IN THE SMALL PLANT?
Can we agree upon the type of fuel to the combustion of which each type of stoker is best adapted? How large must a plant be to warrant the use of a mechanical stoker?

8 WHAT EXPERIENCE HAVE YOU HAD IN THE USE OF WOOD AS FUEL? TO WHAT EXTENT IS WOOD AVAILABLE AS A FUEL?
The coal shortage has occasioned the use of wood fuel in many unwonted places. Accounts of experience that will be helpful are solicited.

9 WHAT COAL ECONOMIES CAN BE EFFECTED IN RESIDENCE HEATING?
He who could make one ton of coal do the work of two during the past winter, not only conserved the coal for his neighbor and saved his own money but was comfortable when he might have otherwise been cold. How can it be done?

10 WHAT COAL ECONOMIES CAN BE EFFECTED IN THE SMALL STEAM PLANTS?
Plants which are not sufficiently important departments of their industries to warrant expert supervision and are too small to support real engineers waste a lot of coal and steam in the aggregate. What are the principal sources and methods of waste and how can they be avoided and corrected?

11 WHAT EXPERIENCES HAVE YOU HAD WITH THE STORAGE OF COAL?

12 While the above topics are all that can be suggested for discussion, additional short papers on any fuel topic are desired for publication. Items of interest on fuel performance should be sent to the Secretary. A few additional topics are suggested:
a To what extent and where will the gas producer be used to produce economies?
b To what extent is natural gas being used as a fuel for power purposes?
c What is the relative economy of the locomotive of 1900 and today?
d What proportion of the coke is made in by-product ovens?
e What are new and important developments in methods of burning coal?
f What economies have resulted from recent practice in making brick settings leakless?
g To what extent is coke being used for residence heating?
h Is automatic air supply correctly proportioned to coal supply possible?

John Fritz Medal

On Wednesday, April 17, at 8.30 p. m., there will be held in the auditorium of the Engineering Societies Building, New York, a meeting at which the John Fritz Medal will be publicly presented to J. Waldo Smith, Mem.Am.Soc.M.E., for "Achievements as Engineer in Providing the City of New York with a Supply of Water." Col. John J. Carty, Past-President, American Institute of Electrical Engineers, will preside. The medal will be presented by Ambrose Swasey, Past-President Am.Soc.M.E., and addresses will be given by other speakers.

AMONG THE LOCAL SECTIONS

THE Spring Meeting at Worcester will afford an opportunity for representatives of the Sections to hold a conference. They will meet at luncheon with the Council on Wednesday, June 5, at which time addresses will be made by President Charles T. Main and Dr. Ira N. Hollis. The sessions of the Spring Meeting will be devoted to a large extent to developing ways and means by which the Society can speed up and increase the service which is being patriotically rendered the Government. This Sections Conference will therefore assume proportions almost international in importance, because it is largely through the medium of the Sections that the Society can achieve undertakings of this nature. Several of the Sections have already held meetings which promise to prove of enormous assistance in winning the war. In fact, the dominant note in Sections activities is that nothing is now worth while which does not contribute to this end.

The meeting of the New York Section on non-essential industries, an extended account of which is given in this issue of THE JOURNAL, has aroused more general interest than any meeting held by that Section in years. The press gave considerable space to a report of the meeting, the New York *Evening Post* devoting practically two columns to it. Representatives of a large variety of trades and industries were present and the journals specially devoted to their interests contain full accounts of the discussion. A resolution was passed at the meeting to the effect that the Society organize to develop the use of any of the available equipment and working forces of plants engaged in the manufacture of anything not directly necessary to winning the war. In this way the disturbance to the industries will be minimized, and their plants kept working to capacity.

The Committee on Sections has distributed to the chairman and secretary of each Local Section a record book. This is arranged in loose-leaf style and contains forms for the reporting of meetings, concise statements relative to the By-Laws governing Sections activities, the requirements for membership, and the privileges thereof, and a description of the publications and of the library. There are forms for recording details about the various committees of each Section, a history of the Section, the development of special mailing and telephone lists, a diary for notable events during the year, the development of papers for meetings, a balance sheet, and corrected lists of the personnel of the Council and Sections Committees with their addresses. These record books should help the Sections officers in the organization of their work, and thereby give them more time for the important work of preparing for meetings.

Section Meetings

ATLANTA

February 12. At the invitation of Mr. Robert Gregg the members of the Section participated in a dinner at the Druid Hills Golf Club.

Chairman Elsas gave a report of the conference of Sections delegates at the Annual Meeting. The discussion which followed developed a general feeling that the affiliated technical societies should receive more active support by the local sections of the national engineering societies.

CECIL P. POOLE,
Section Secretary.

BALTIMORE

March 12. At the fourth regular meeting the attendance was the largest on record, and great interest was shown in the discussions presented on canning of foods, as this is one of Maryland's most important industries.

The first paper of the evening, presented by J. H. Shrader, Assistant Physiologist, U. S. Department of Agriculture, outlined the general process of canning, referring particularly to tomatoes, which are the staple product of Maryland. Each process used was described and illustrated, its faults and inefficiencies from a food-utilization viewpoint pointed out, and it was shown that fully 45 per cent of the food value of the tomato as delivered at the plant is wasted in the process. This waste occurs in storage during excessive supply, in poor sorting, in wasteful peeling and in can filling.

The question of the manufacture of "tomato paste" was considered, and as the waste, labor charge and loss in this process is very small, it offers wonderful opportunities for the efficient operation of canning plants. The food value of the product is as high as that of the regular canned goods, while the bulk is tremendously reduced, thus reducing space and freight and providing a cheaper product than the ordinary canned tomato.

Prof. Julian C. Smallwood, Mem.Am.Soc.M.E., who has conducted extensive researches in the use of steam in the canning industry, and is an authority on this subject, presented the second paper, on Economy in the Use of Steam, by means of diagrams. The wastes covering washers, scalders, kettles, exhausters and process kettles, together with radiation were traced in the various steps of the process and the ways and means of elimination were discussed. A plant where losses of this kind were reduced to a minimum was described and it was shown that the boiler hp. necessary could be reduced from 265 to 140, with a corresponding saving of fuel. Experiments showed the ordinary exhauster process is most ineffective in securing the result desired. Great opportunities for economy in the process kettles and the advantage of using low-pressure steam are offered.

The last paper was delivered by J. C. Taliaferro, plant manager, Continental Can Co., on The Filling and Closing of the Modern Can. The problem for engineers is to design a filling machine that will put the required amount, without waste, into each can. The Government requires a certain standard of filling the cans, and canners usually overfill their cans thus making it impossible to exhaust properly and thereby spoiling the contents. When cans are overfilled some liquid must be spilled before exhausting, and this is wasted. Until our engineers can design such equipment we must continue to thus needlessly waste a large proportion of our food products in the process of canning.

A. G. CHRISTIE,
Section Secretary.

BIRMINGHAM

At the February meeting held jointly with the Alabama Technical Association, C. B. Davis, Mem.Am.Soc.M.E., delivered a paper on Fuel Conservation.

March 21. Mr. J. A. Sirnit, of the Alabama Power Co., gave a talk on Water and Fuel Equipment Warrior River Reserve Station. A more detailed account of the meeting will appear in a later issue.

W. LEE ROUECHE,
Section Secretary.

BOSTON

March 16. A subject of the greatest importance and most serious to the American nation at the present time was the address on Man Power delivered by J. Parke Channing. A more detailed account of the meeting will be published in a later issue of THE JOURNAL.

W. G. STARKWEATHER,
Section Secretary.

BUFFALO

February 20. After a trip through the Buffalo High School, Chairman F. E. Cardullo gave a talk on Manual Training, emphasizing its general educational value to the student.

March [illegible]. Under the auspices of the American Chemical Society Section an illustrated lecture on Some Phases of Glass Making was delivered by Dr. E. C. Sullivan, Chief Chemist of the Corning Glass Works. The lecture was extremely interesting as the speaker has done much toward meeting the glass situation in this country since the exports of Germany have been cut off.

March 13. The Hydroelectric Power Problem and the general considerations involved in the exploitation and design of hydroelectric plants formed the subject of an address by J. A. Johnson. The economic question of the relation between the location of available power and the location of industries was discussed and the speaker traced the advantages and disadvantages in the generation and transmission of power over short and long distances; the value of the steam plant and the economic relations between the two.

March 20. Under the auspices of the S.A.E. Section a paper on Worm Gear Bronze was delivered by W. M. Corse.

March 27. A night of "Mystery" held under the auspices of the A.S.M.E. Section. Details of the meeting not being available at this time, will be published in a later issue.

E. B. NEIL,
Section Secretary.

CHICAGO

March 1. The subject of the meeting was the Coal Situation and was discussed by Joseph Harrington, Mem.Am.Soc.M.E., and Prof. H. H. Stock, head of the Mining Department, University of Illinois, and also chairman of the Conservation Committee of the Fuel Administration for Illinois. Mr. Harington dealt with one phase of the subject, plant control, and showed how the efficient equipment of a plant and the keen observation on the part of the employees will increase the efficiency of the plant. He emphasized the fact that employers very often fail to grasp the point that while conscientious, intelligent operatives often overcome certain losses by inefficient machinery, it is essential to have the newer type of machinery installed in order to work efficiently. The question of improving plant operation by education or by autocratic overseeing by the Government was also discussed. Mr. Harrington claimed in addition to having educated engineers as operatives it is also necessary to have compulsory measures through Government committees in order to have any practical effect on the consumption of coal of the country.

Prof. Stock in discussing the coal situation showed the lack of fuel to meet the present demands and advocated restrictions in unnecesary demands.

A. L. RICE,
Section Secretary.

INDIANAPOLIS

January 25. At a joint meeting of the Indiana Engineering Society with the A.S.M.E. and A.I.E.E. Sections which lasted throughout the entire day, the following papers were presented at the morning session: Concrete Roads versus Other Types of Construction, by W. E. Graves, Assistant City Engineer, South Bend, Ind.; Discussion on Roads and Recent Development in Brick Paving, by E. B. Smith, Laporte, Ind.; Indiana Market Highways in War Time, by W. S. Moore, Chairman State Highway Commission; History of an Old Bridge, by J. S. Spiker, Vincennes, Ind.; and Water Bound Gravel Roads, by Karl L. Hanson, Connersville, Ind. Motion pictures showing the construction of buildings and roads at the cantonment at Camp Dodge, Iowa, were presented by C. D. Franks, of the Portland Cement Association.

At the afternoon session Colonel Slaughter, U. S. A., presented a paper on Recent Development in Signaling at the Front, in which he described the use of carrier pigeons, message bearers, sound signaling and radio communication.

Mr. J. F. Gilchrist, Vice-President of the Commonwealth Edison Company of Chicago, delivered a paper on Financial Problems of the Utility in War Times, pointing out that as utility companies generally have an investment of from five to six times their annual gross receipts, whereas in many other lines of business the annual gross receipts and investments are about the same, public utility corporations require large amounts of capital for their operation. This capital has been raised in the past principally by the sale of bonds and preferred stock, for which there is little sale at this time. An estimated sum of $100,000,000 will have to be raised in the year 1918 to take care of the necessary expansion of the public utilities. In past years, a number of plants, especially in Pittsburgh and the Atlantic Coast districts, have had so many demands for power to take care of war needs that they have found it necessary to ask the Priority Committee at Washington to designate which plants should be given preference. Some industries were given current for five days of the week instead of six, or for eighteen hours instead of twenty-four. As expenses, especially local, are costing the utilities more than in the past, it is apparent that if a number of the utilities are to remain solvent, rates must be raised by the Commission.

Considerable discussion followed, led by H. O. Garmon, Chief Engineer of the Indiana Public Service Commission, and George Hubley, Manager of the Merchants' Heat & Light Co. of Indianapolis.

An illustrated lecture on Concrete Ships and Barges was given by J. E. Freeman, of the Portland Cement Association, Chicago, Ill., pointing out the great possibilities of concrete, and of how stability is maintained in ships and barges.

A paper entitled Vocational and Industrial Education was given by A. S. Hurrell, Assistant Superintendent of Vocational and Industrial Education of the Indianapolis Public Schools.

At the evening session Mr. Will H. Hays, Chairman of the State Council of Defense of Indiana, delivered an address on the subject of The Engineer and the State Council of Defense, in which he brought out that every citizen has a patriotic duty to perform, but upon the engineer particularly the burden rests. The Indianapolis Engineers' Club was praised most warmly for the active influence and help extended to the state in the organization of the Battalion of Engineers of Indiana.

The concluding number on the program was an illustrated lecture by W. S. Culver, District Engineer of the General Electric Company, Cincinnati, Ohio, on The King of the Rail.

W. A. HANLEY,
Section Secretary.

NEW ORLEANS

March 11. At a meeting of the Louisiana Engineering Society, to which the members of the A.S.M.E. Section were invited, A. M. Lockett, Mem.Am.Soc.M.E., delivered a lecture on The New Orleans Industrial Canal. Further details regarding the meeting will be published in a later issue of THE JOURNAL.

H. L. HUTSON,
Section Secretary.

NEW YORK

February 21. How non-essential work might be turned into aid toward winning the war, was a subject which brought forth much discussion at the meeting. Ten or twelve speakers representing as many industries discused the subject, each setting forth his reason for considering the industry he represented, an essential one. Among the speakers were the following: Calvin W. Rice, Secretary, A.S.M.E.; Frederick W. Keough, Editor of *American Industries*, published by the National Association of Manufacturers; William Hamlin Childs, President of the Barrett Company; Sterling H. Bunnell, of R. Martens & Company; Horace B. Cheney, Jr., Vice-President of Cheney Brothers; Charles T. Main, President, A.S.M.E.; J. H. Haas, of the Loft Candy Company; Erik Oberg, Editor of *Machinery;* C. R. McMillen, of the Union Paper Bag Corp.; Frank Mossberg, of Attleboro, Mass.; P. W. Henry, of the American International Corporation, and Prof. D. D. Jackson, of Columbia University.

A detailed report of the meeting will be found in the Technical Section of this issue.

March 19. Terminal Facilities of New York was the subject of the meeting and was discussed by the following speakers, each covering a special phase of the subject: A. B. Pough presented the first topic, on Demands, including Pre-War, War, After-War and Future Demands. B. F. Cresson, Jr., discussed Land Facilities to meet the demands, such as railroads, marginal railroads, trucking and warehouses. W. J. Barney spoke on the Water Facilities to meet the demands, such as harbor, rivers, canals, docks, lighterage and mechanical. Deficiencies and Their Correction were discussed by George H. Pride. Agencies in Development, such as private capital, city, state, and national Government, were covered by Ira Place, and Charles Whiting Baker gave a résumé of the entire subject, offering a great many practical suggestions.

W. HERMAN GREUL,
Section Secretary.

PHILADELPHIA

March 26. Dr. S. W. Stratton of the United States Bureau of Standards delivered a talk on Recent Developments in Methods of Measurement. Further details will be published in a later Journal.

John P. Mudd,
Section Secretary.

PROVIDENCE

March 4. At the first Annual Smoker and General Meeting of the Providence Engineering Society, Gov. R. Livingston Beekman gave an interesting acount of his experiences at the battlefront.

March 12. Under the auspices of the Machine-Shop Section, Henry K. Spencer, of the Blanchard Machine Company, read a paper on The Production of Flat Surfaces by Modern Surface Grinding Machines.

March 13. At the Power-Section Meeting Mr. Warren F. Hodges presented a paper on Motor Troubles, and a second paper on the subject of Automobile Starters was given by Alfred Maille.

March 22. Mr. G. Douglas Wardrop, Editor of the *Aerial Age*, gave an interesting lecture on War in the Air. Mr. Calvin W. Rice, Secretary of the A.S.M.E., delivered a short address on Methods of Coöperation in Meeting Present Emergencies.

James A. Hall,
Correspondent.

Student Branch Meetings

The Metropolitan Student Branches of the Society located at Columbia University, New York University, Polytechnic Institute of Brooklyn and Stevens Institute of Technology, will hold the usual spring meeting at the Engineering Societies Building on Tuesday, April 9. There will be an afternoon and an evening session, with a buffet supper between the sessions.

The committee in charge of the arrangements is composed of two representatives of each of the Student Branches, with Herbert Lowenstein as chairman and Lincoln V. Aquadro as secretary. The committee has been exceedingly fortunate in getting the acceptances of the following speakers: F. R. Hutton, Richard B. Sheridan, Ira N. Hollis, G. D. Wardrop, M. H. Avram and Jack Armour. Other prominent engineers have been invited with a view to having a number of short interesting talks in preference to a few lengthy ones. The subjects to be touched upon include aviation, marine engineering, the need for technical training, especially in war times, the engineering requirements of our allies, the railroad engineer, and the young engineer in the army and navy.

The New York Section of the Society has decided to coöperate with the students by joining with them in this meeting and making it the April meeting of the Section.

The lecture by Mr. Wardrop on War in the Clouds is illustrated by motion pictures and lantern slides, and brings this phase of the situation up to the minute.

Members of the Society are especially urged to attend this meeting, not only to give these embryo engineers an opportunity to meet some of those established in the profession, but also because of the opportunity afforded for meeting prospective assistants to take positions upon graduation or temporarily during the vacation period. It is hoped that a number of members will make a point of being present to give encouragement to these young engineers in making a success of the meeting. All technical students, whether student members or not, are likewise urged to attend. Those desiring to participate in the supper should notify the secretary's office not later than noon, April 9.

UNIVERSITY OF CINCINNATI

February 21. A paper on the Construction of Concrete Ships and Barges was presented by J. E. Freeman.

March 21. A paper on Shop Kinks was presented by Henry Ritter, Mem.Am.Soc.M.E.

Professor John T. Faig, Mem.Am.Soc.M.E., delivered a paper on The Economic Use of Coal by Communities. In view of the increasing need of conservation at this time, a method of using coal by which all of the by-products are saved was fully discussed.

Mr. C. W. Carpenter, Mem.Am.Soc.M.E., who has had considerable experience in training thousands of women for war industry, delivered an interesting lecture on The Training of Women for Industry.

J. T. Faig,
Section Secretary.

CARNEGIE INSTITUTE OF TECHNOLOGY

February 13. An illustrated talk was given by W. C. Wright on Modern Foundry Methods and Equipment, which showed present foundry practice and the various devices for increasing the output and decreasing the number of skilled molders necessary. The subject of the woman worker was presented, and the matter of making her surroundings more pleasant and sanitary and the need for safety devices in the line of work in which she is employed were discussed.

H. D. Krummel,
Branch Secretary.

UNIVERSITY OF COLORADO

March 7. Professor Black delivered an illustrated lecture on Properties of Commercial Steam Pipe Coverings. The lecture covered experiments performed at the University of Wisconsin. The different methods of measuring heat dissipation through pipe coverings, and the means of measuring temperatures, giving preference to the copper-constantan thermocouple, were discussed. Various curves were shown indicating the comparative insulating properties of different coverings and also the saving possible through efficient covering.

H. O. Croft,
Branch Secretary.

POLYTECHNIC INSTITUTE OF BROOKLYN

March 8. Benjamin Offen was elected treasurer, to succeed Joseph L. Kopf.

Mr. Arthur Seubert, in his talk on Engineering Education, pointed out that by affiliating with engineering or college societies the student's powers of leadership, tact and resourcefulness are developed.

A special war-time course in radio engineering, covering theory, code and laboratory work, is being given at the Institute and is open to seniors in mechanical engineering.

Nathan N. Wolpert,
Branch Secretary.

UNIVERSITY OF WASHINGTON

An inspection trip was made to the Ford assembling station and to the sub-stations of the Seattle Light & Power Company. Forty members and guests of the university participated.

The university is coöperating with the Government by having a Reserve Officers Training Corps in which underclassmen receive eight hours of training a week with upperclassmen as officers and members of the faculty as instructors, the latter being in the R.O.T.C. An A.U.S. Naval Training Station is located on the Campus with an enrollment of about a thousand and a course for marine operating engineers under the direction of the U. S. Shipping Board is given by the mechanical engineering faculty to men from all over the West and Southwest. Over a thousand men from the University of Washington are now in the service, and a good share from the engineering school are now in various branches of the Engineering Corps and other branches of service.

Fairman B. Lee,
Branch Secretary.

TENTH ROLL OF HONOR

***ONE HUNDRED AND SIXTY-EIGHT** additional names of members of The American Society of Mechanical Engineers are added to our ever-lengthening Roll of Honor, and the stars on the service flag now number over 900.*

Abercrombie, James H., Captain, British Army.
Abernethy, W. K., Aviation Corps, U. S. Army.
Alden, J. L., Second Lieutenant, Ordnance Department, N. A.
Allen, Henry A., Colonel, Commanding 108th Engineers, 33rd Division, Camp Logan, Houston, Texas.
Antonsanti, Louis, 2nd Officers' Training Camp, San Juan, Porto Rico.
Arkell, William C., First Lieutenant, Ordnance Officers' Reserve Corps.
Ashley, Edward E., Jr., First Lieutenant, Engineering Section, Signal Corps, U. S. Army.
Badowski, Alfred, Captain, Ordnance Department, U. S. Army.
Baird, James T., Jr., Captain, Ordnance Officers' Reserve Corps.
Baker, Philip C., Lieutenant, 79th Aero Squad, American Expeditionary Forces, France.
Banquet, Camille, Jr., Second Lieutenant, 1st Company, Coast Artillery Corps, Fort Mott, New Jersey.
Barry, Thomas J., Company A, 37th Engineers, Fort Meyer, Va.
Beard, Theodore H., Lieutenant, Sandy Hook Proving Ground, Fort Hancock, New Jersey.
Behr, F. J., Major, Coast Artillery Corps, U. S. Army.
Bensel, John A., Major, Engineer Officers' Reserve Corps, U. S. Army.
Bolles, Frank G., Major, Ordnance Department, U. S. Army.
Bond, William L., First Lieutenant, Ordnance Officers' Reserve Corps, Frankford Arsenal, Pa.
Bowles, Hardy, Captain, 23rd Engineers, American Expeditionary Forces, France.
Bres, Edward W., Lieutenant, 312th Engineers, Camp Pike, Arkansas.
Brooks, J. Ansel, Captain, Aviation Section, Signal Reserve Corps.
Brown, Clinton, First Lieutenant, Carriage Section, Production Division, Ordnance Officers' Reserve Corps.
Brown, Eugene L., Jr., First Lieutenant, Engineer Officers' Reserve Corps.
Buckley, Captain, Ordnance Officers' Reserve Corps, Frankford Arsenal, Philadelphia.
Buyers, A. S., Captain, Coast Artillery Corps, U. S. Army.
Campbell, Jeremiah, Major, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.
Carothers, Charles G., Captain, Company 1, Engineer Officers' Reserve Corps.
Carter, William D., Captain, Ordnance Officers' Reserve Corps.
Case, Milo M., Major, Inspection Department, Ordnance Officers' Reserve Corps.
Chapman, Edmund E., Captain, Ordnance Officers' Reserve Corps.
Clarkson, Robert C., Jr., Mechanical Engineer, Signal Corps, U. S. Army.
Coburn, Frederic G., Naval Constructor, U. S. Navy.
Cole, C. L., Captain, Ordnance Officers' Reserve Corps.
Conant, William S., Major, Ordnance Officers' Reserve Corps.
Cone, Hutchinson J., Commander, U. S. Navy, Navy Department, Washington, D. C.
Converse, Bernard T., Major, Ordnance Officers' Reserve Corps, Watervliet Arsenal, Watervliet, New York.
Cordes, Paul H., First Lieutenant, Company C, 30th Engineers, Gas and Flame Regiment, Fort Myers, Va.
Cutler, James B., Lieutenant, U. S. Reserve, Battery E, 319th Field Artillery, Camp Gordon, Georgia.
Davies, Clarence E., First Lieutenant, Ordnance Officers' Reserve Corps, Frankford Arsenal, Pa.
Davies, T. R., First Lieutenant, Ordnance Officers' Reserve Corps.
Dexter, Harris E., Lieutenant, 30th Engineers, American Expeditionary Forces.
Doll, William E., Lieutenant, 35th Engineers, U. S. R., Camp Grant, Rockford, Ill.
Eddison, Barton, Lieutenant, Junior Grade, U. S. Naval Reserve Force.
Eddy, Benjamin S., First Lieutenant, Engineer Officers' Reserve Corps.
Eisenhart, H. W., Captain, Production Division, Carriage Section, Ordnance Officers' Reserve Corps, U. S. A.
Engesser, B. M., Aviation Section, Signal Corps, Army School of Military Aeronautics, M. I. T.
Evans, B. R., Machinist's Mate, 2nd Class, United States Navy, U. S. S. B 1 Submarine.
Farrington, Thomas H., Captain, Engineer Officers' Reserve Corps, Fort Leavenworth, Kansas.
Ferguson, W. Craig, First Lieutenant, Ordnance Officers' Reserve Corps.
Flagg, Paul M., Private, Company F, 304th Engineers, National Army, Camp Meade, Maryland.
Foord, James L., Lieutenant-Commander, N. N. V., U. S. Navy, U. S. Training Station, Great Lakes, Ill.
Ford, John D., Rear Admiral, U. S. Navy.
Forsyth, James M., Candidate Second Officers' Training Camp, Fort Sheridan, Ill.
Fraser, D. Ross, First Lieutenant, Engineer Officers' Reserve Corps.
Fravens, Frank H., Company A, 42nd Engineers, Camp American University, Washington, D. C.
Fulweiler, John E., Ensign, U. S. Naval Reserve Corps, U. S. S. *James*.
Gallaher, Charles W., First Lieutenant, Iowa Engineers, Brownsville, Texas.
Gibbs, Charles W., Machinist's Mate, Second Class, U. S. Naval Reserve Force.
Gibson, Julian B., Second Lieutenant, Quartermaster's Corps, National Army, Camp Meade, Maryland.
Gilbert, Huntley H., Captain, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Ill.
Goodier, Homer W., First Class Private, Aviation Section, Signal Enlisted Reserve Corps.
Haasis, P. W., Aviation Section, Signal Officers' Reserve Corps.
Hawes, Alex. G., Captain, Ordnance Officers' Reserve Corps.
Hayes, William Parsons, Lieutenant, Fleet Naval Reserve, U. S. S. *Niagara*.
Heidelburg, Fred M., First Lieutenant, Inspection Division, Ordnance Department, U. S. A.
Henry, Alexander S., Jr., Aviation Corps, No. 104th Aero Squadron, U. S. Army.
Hicks, Rufus W., Jr., First Lieutenant, Ordnance Officers' Reserve Corps.
Horner, Benjamin B., Second Lieutenant, Engineer Officers' Reserve Corps, 311th Engineers, Camp Grant, Ill.
Hulburt, Wynne D., Second Lieutenant, 71st Regiment Engineers (Railway), American Expeditionary Forces, France.
Husted, Clifford M., Captain, Engineers, U. S. Army.
Hutchinson, H. H., Captain, Ordnance Officers' Reserve Corps.
Iddles, Alfred, First Lieutenant, Engineering Bureau, Ordnance Officers' Reserve Corps.
Ireland, Mark L., Major, Quartermasters' Corps, Fort Sam Houston, Texas.
James, Richard M., Private, Ordnance Training School, Pittsburgh, Pa.
Jamieson, Charles C., Colonel, Ordnance Department, N. A.
Jenks, Glen F., Lieutenant-Colonel Ordnance Department, American Expeditionary Forces, France.
Junkersfeld, Peter, Lieutenant-Colonel, Quartermaster Corps, N. A.
Keenan, Walter M., First Lieutenant, Aviation Section, Signal Officers' Reserve Corps.
Keet, Clarence T., Company A, 304th Engineers, Camp Meade, Maryland.
Kennedy, Grafton S., Lieutenant, Coast Artillery Corps, U. S. Army, Fort Morgan, Ala.
Kent, Robert W., First Lieutenant, Ordnance Officers' Reserve Corps.
Kessler, Herbert, First Lieutenant, Ordnance Officers' Reserve Corps.
King, William R., Major, Ordnance Officers' Reserve Corps.
Kingsbury, Chester L., Lieutenant, Ordnance Officers' Reserve Corps.
Knight, William, First Lieutenant, Aviation Section, Signal Officers' Reserve Corps.
Koch, Charles, Ordnance Draftsman, Philadelphia Navy Yard.
Lane, Abbot A., First Lieutenant, Signal Officers' Reserve Corps.
Lewis, J. Clifford, Construction Department, Signal Corps, U. S. Army.
Lipsner, Benjamin B., Captain, Signal Corps, U. S. Army.
Logan, Orwell, National Army, Camp Upton, Yaphank, Long Island.
Lonn, Julius M., First Lieutenant, Ordnance Department, Frankford Arsenal, Philadelphia, Pennsylvania.
Lowman, Roy L., Lieutenant, United States Naval Reserve Force.
MacDonald, Howard D., First Lieutenant, 131st U. S. Infantry, Camp Logan, Texas.
McCune, Joseph C., First Lieutenant, Engineer Officers' Reserve Corps.
McKinney, William P., U. S. Navy, Naval Aviation Corps.
McMurray, J. H., Captain, Ordnance Department, N. A.
Magee, Christopher, Company M, 332d Infantry, Camp Sherman, Ohio.
Martin, Edward, U. S. Navy, Naval Aviation Corps.
Massey, George B., Lieutenant, Junior Grade, Fleet Reserve.
Maxfield, Howard H., Colonel, 19th Regiment Engineers (Railway), American Expeditionary Forces, France.

Maxwell, George L., Company A, 29th Engineers, American Expeditionary Forces.
Meigs, Robert R., First Lieutenant, 19th Regular, Engineers (Railway), American Expeditionary Forces, France.
Merrill, Albert S., First Lieutenant, Inspection Division, Ordnance Officers' Reserve Corps.
Messner, Manfred, Private, Company K, 312th Infantry, Camp Dix, N. J.
Meyler, Robert G., First Lieutenant, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Rock Island, Ill.
Miller, Clarence A., National Army.
Moody, Frederick H., Major, 116th Battalion, Canadian Infantry, France.
Moyer, Will D., Captain, Coast Artillery, Officers' Reserve Corps, Fort McKinley, Portland, Maine.
Nesbit, Joseph, N. G., Ordnance Division, Sandy Hook Proving Ground, Fort Hancock, New Jersey.
Norris, John B., Jr., First Lieutenant, Engineer Officers' Reserve Corps.
Osgood, W. H., Lieutenant, United States Navy.
Overmire, Wilfred J., Private, Company C, 334th Infantry, Camp Zachary Taylor, Kentucky.
Packard, H. N., Lieutenant, Junior Grade, Naval Reserve Force.
Palmer, Brian C., Science and Research Division, Signal Corps, U. S. Army.
Parkhurst, Harleigh, Major, Field Artillery, U. S. Reserve, 14th Field Artillery, Fort Sill, Oklahoma.
Pemberton, C., Lieutenant, Ordnance Department, Camp Jackson, South Carolina.
Pohle, Richard F., First Lieutenant, Inspection Department, Ordnance Officers' Reserve Corps.
Powell, Paul R., First Lieutenant, Engineer Officers' Reserve Corps, U. S. Army.
Ray, Martin H., Captain, Aviation Section, Signal Corps, U. S. A.
Reilly, Charles J., Company C, 21st Engineers, Camp Grant, Rockford, Ill.
Rider, David S., Private, Company E., Private, 10th Engineers (Forestry), American Expeditionary Force, France.
Riley, Joseph C., Major, Air Service, Signal Corps, American Expeditionary Forces, France.
Roberts, Richard F., Equipment Division, Signal Corps, U. S. A.
Rosenfield, Harold, Aviation Section, Signal Officers' Reserve Corps.
Ross, Sir Charles H. A. F. L., Lieutenant, Ordnance Officers' Reserve Corps, Fort Hancock, Sandy Hook, New Jersey.
Russ, John B., First Lieutenant, Engineer Officers' Reserve Corps.
Ryder, Frederick W., 1st Battery, Reserve Officers' Training Camp, Fort Niagara, New York.
Sauers, John A., First Lieutenant, Ordnance Officers' Reserve Corps, Frankford Arsenal, Bridesburg, Pennsylvania.
Schaum, Otto W., Aeronautical Mechanical Engineer, Signal Corps, U. S. Army.
Schmidt, John D., Ensign, U. S. Naval Reserve Force.
Schupp, Arthur A., Second Lieutenant, Signal Corps, U. S. Army.
Scott, Rossiter S., Captain, Engineers, U. S. Reserve, 8th Company, Camp Lee, Va.
Sharkey, W. E., Lieutenant, Ordnance Officers' Reserve Corps.
Sharp, Ralph E., Camp Meade, Maryland.
Slade, Henry L., Jr., First Lieutenant, Ordnance Officers' Reserve Corps.
Spaulding, Hollon C., Captain, Quartermaster Reserve Corps, Army Transport Service.
Streeter, Robert L., Major, Ordnance Department, National Army.
Stults, William R., Private, National Army, 18th Company, 5th Training Brigade, Depot Brigade, Camp Devens, Ayer, Mass.
Stureman, Robert V., Quartermaster Corps, Camp Logan, Houston, Texas.
Swift, Harley L., First Lieutenant, 16th Regiment Engineers (Railway), American Expeditionary Forces, France.
Swinton, David R., First Lieutenant, National Army.
Thompson, John T., Colonel, United States Army.
Tower, Glenn L., Lieutenant, Ordnance Department, National Army.
Trowbridge, Amasa, Major, Ordnance Officers' Reserve Corps, Watervliet Arsenal, Watervliet, New York.
Tuttle, George W., Aviation Section, Signal Reserve Corps.
Van Keuren, E. B., Captain, Ordnance Officers' Reserve Corps.
Vauclain, A. C., Major, Ordnance Officers' Reserve Corps.
Vehslage, H. E., First Lieutenant, Purchase Section, Gun Division, Ordnance Officers' Reserve Corps.
Vogt, Clarence W., Captain, Ordnance Department, N. A.
Voorhees, John R., Lieutenant, Ordnance Department, U. S. Army, Sandy Hook Proving Ground, Fort Hancock, N. J.
Waddell, Robert, Lieutenant, Royal Flying Corps, British Army.
Warren, William H., Corporal, Headquarters Company, 340th Field Artillery, National Army, Camp Funston, Kansas.
Webster, Lawrence B., Captain, Ordnance Officers' Reserve Corps.
Weeks, Paul, Captain, Motor Equipment Section, Ordnance Officers' Reserve Corps.
Wegnerer, Francis A., Naval Reserve Flying Corps.
Weinberg, George S., Major, 30th Engineers, American Expeditionary Forces, France.
Welford, P. G., Gunner, Canadian Field Artillery.
Wells, G. A., Captain, Carriage Division, Motor Equipment Section, Ordnance Officers' Reserve Corps.
Westervelt, W. I., Colonel, Field Artillery, N. A., American Expeditionary Forces, France.
Wheeler, F. B., Gas Defense Service, American Expeditionary Forces, France.
Whitlock, Elliott H., Lieutenant-Colonel, 24th Engineers, N. A., American Expeditionary Forces, France.
Wieland, C. F., Captain, Ordnance Officers' Reserve Corps, Manila Ordnance Depot, Manila, P. I.
Wightman, George A., Sergeant, Ambulance Company, Training Camp Zachary Taylor, Louisville, Kentucky.
Wilbur, R. L., First Lieutenant, Ordnance Officers' Reserve Corps, U. S. Army.
Williams, Harold E., Captain, Field Artillery, Officers' Reserve Corps.
Williams, R. G., Captain, Ordnance Officers' Reserve Corps.
Woodcock, William E., Second Lieutenant, Engineer Officers' Reserve Corps.
Ycasiano, F. R., Captain, Radio Company, Field Battalion, Signal Corps, National Guard, Philippine Islands.
Zeiger, Kenneth G., Student Officers' Training Camp, 2nd Coast Artillery Corps, Fort Winfield Scott, California.
Zink, Robert E., Captain, Ordnance Officers' Reserve Corps.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by April 16 in order to appear in the May issue.

CHANGES OF POSITION

Henry A. Stringfellow has left the employ of the Epping-Carpenter Pump Company, Pittsburgh, Pa., to assume the position of first assistant engineer with R. Winthrop Pratt, consulting engineer, on the design of the new filtration plant for the City of Detroit, Mich.

John H. Wilhelm, formerly superintendent of the Gage Department of Frankford Arsenal, Frankford, Pa., has become affiliated with the Blair Tool and Machine Works, Inc., New York, in the capacity of chief engineer.

B. F. Safberg has left the employ of the Babcock and Wilcox Company and has become identified with the production department of the Emergency Fleet Corporation, Washington, D. C., in charge of boiler production.

John W. Mershon has resigned his position as mechanical engineer of Remington Arms, Bridgeport, Conn., to take a position as plant engineer at Bayles Shipyard, Port Jefferson, N. Y.

George M. Keenan, test engineer of the Union Electric Company, St. Louis, Mo., has assumed the duties of chief engineer of the Little Rock Railway and Electric Company, Little Rock, Ark.

Leo Loeb has severed his connection with the Coal Companies with which he has been associated within the past four years, and has joined the organization of Day and Zimmermann, Inc., of Philadelphia, Pa.

E. H. NILSON has resigned as chief engineer of the Blake-Knowles Plant of the Worthington Pump and Machine Corporation, and has accepted the position of general works manager with the Griscom-Russell Company, of New York, with headquarters at Massillon, Ohio.

ROBERT H. SCHAFER has resigned as mechanical superintendent of the Bridgeport Brass Company, to accept a position as mechanical engineer of design and equipment of the Brown's Copper and Brass Rolling Mills Company, Ltd., Toronto, Ont., Canada.

DANIEL M. SACHS, until recently vice-president and general manager of the Northern Pipe Line Company, Oil City, Pa., has accepted the position of general manager of the New York Transit Company, Binghamton, N. Y.

A. H. LANE has severed his connection with the Eastern Machinery Company, New Haven, Conn., with which firm he held the position of engineer for the past three years, and has taken a position with the Grant Hammond Manufacturing Corporation, of New York, as special machine designer.

Z. E. SARGISSON has resigned his position as chief designing engineer of the Illinois Traction System, Peoria, Ill., to accept the position of assistant works engineer of the Pan Motor Company, of St. Cloud, Minn.

O. D. A. PEASE, formerly assistant foreman of the test department of the Pennsylvania Railroad at Altoona, Pa., has accepted an appointment with the Bureau of Explosives, as inspector, with headquarters in New York.

EARL E. ADAMS, lately sales manager of the powdered coal department of the Bonnot Company, Canton, Ohio, and for some years in charge of gas producer work for the Power and Mining Machinery Company, has accepted a position as sales engineer for the Smith Gas Engineering Company, and will shortly be located at Dayton, Ohio, where the new plant of the Smith Gas Engineering Company is nearing completion.

WILLIAM T. PRICE has recently resigned as manager and chief engineer of the De La Vergne Machine Company, oil engine department, to become president of the P-R Engine Company of New York, and second vice-president of The Rathbun-Jones Engineering Company of Toledo, Ohio, which will undertake the sale and manufacture respectively of Price-Rathbun stationary and marine oil engines built in accordance with a new principle of fuel injection developed by Mr. Price during the past several years.

ANNOUNCEMENTS

The following appointments have been announced by the Worthington Pump and Machinery Corporation: JAMES E. SAGUE, consulting engineer, has been appointed vice-president in charge of engineering and manufacture; WILLIAM GOODMAN, manager of the Laidlaw Plant, appointed assistant to vice-president; WILLIAM SCHWANHAUSSER has been reappointed chief engineer; CHARLES E. WILSON, appointed assistant general sales manager.

ULDRIC THOMPSON, JR., formerly chief engineer of the International Steel and Ordnance Corporation, and who has until recently been serving in an advisory capacity in equipping the new artillery ammunition plant at Rock Island Arsenal, has opened an office at 120 Broadway, New York, under the firm name of Uldric Thompson, Inc., consulting and industrial engineers.

J. C. BERTSCH has resigned his position as refrigerating engineer with The Westinghouse Electric and Manufacturing Company machine works, to engage as consulting engineer in the design of thermo-compressors for air, steam and ammonia, and apparatus for rubber mill, gasoline extraction and marine refrigeration, with office in Pittsburgh, Pa.

RICHARD F. ROBERTS has been given an indefinite leave of absence from the Chile Exploration Company, to enter the equipment division of the U. S. A. Signal Corps, Washington, D. C.

CHARLES W. GIBBS has been enrolled in the U. S. Naval Reserve Forces as Machinist's Mate, 2nd Class, and will be detailed for duty at the Fuel Oil Testing Plant, Philadelphia Navy Yard.

HENRY E. LONGWELL announces his resignation as vice-president and general manager of The Westinghouse Air Spring Company, New Haven, Conn.

JAMES A. SHEPARD, vice-president and chief engineer of the Shepard Electric Crane and Hoist Company, Montour Falls, N. Y., gave an interesting talk on Designing at the February 22d meeting of the Shepard Progress Club.

HAROLD I. MARKEY has left the engineering department of the Firestone Tire and Rubber Company, Akron, Ohio, to take the position of assistant chief engineer of the Diamond Chain and Manufacturing Company, Indianapolis, Ind.

A. C. VOORHEES has resigned his position as chief submarine draftsman for the California Shipbuilding Company, to accept the position of assistant to the general superintendent with the Schaw-Batcher Company Pipe Works of San Francisco, which has contracts for 18 freighters for the Emergency Fleet Corporation.

FORREST H. BLANDING, formerly identified with the McEwen Manufacturing Company, Tulsa, Okla., as superintendent, has accepted a similar position with the ordnance works of the Otis Elevator Company, Chicago, Ill.

CHARLES A. MALONEY, efficiency engineer with the United Gas Improvement Company, Philadelphia, Pa., has become affiliated with the Merchant Shipbuilding Corporation, Bristol, Pa., in the capacity of mechanical engineer.

FRANCIS A. WEGENER is no longer connected with the Welsbach Company, Gloucester, N. J., having enlisted in the U. S. Naval Reserve Flying Corps. He is at present under instruction at Columbia University, New York.

FRANK O. WELLS, president of the Greenfield Tap and Die Corporation, is one of the directors of the Lincoln Twist Drill Company, of Taunton, Mass.

ROBERT P. LAY, assistant engineer of the experimental motor division of the Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y., has been transferred to the Garden City, L. I., N. Y., plant of The Curtiss Engineering Corporation.

JOHN YOUNGER of the Pierce-Arrow Motor Truck Company, Buffalo, N. Y., is serving in the engineering division of the motor transport section of the Quartermasters Corps.

ROBERT T. KENT has become associated with Meyer, Morrison and Company, consulting engineers, of New York.

NECROLOGY

JOHN PORTERFIELD SPARROW

John Porterfield Sparrow, for many years a member of the Society, died at his home in Flatbush, Brooklyn, on March 18, 1918. He was born in Portland, Maine, on March 17, 1860.

Mr. Sparrow was an engineer by inheritance and education, his father, John Sparrow, being well known in the engineering field. His early education was obtained in the public schools of Portland, but this was largely supplemented by his father's teachings in physics, chemistry and engineering.

In 1879, being interested in sugar manufacture, Mr. Sparrow was taken to Europe by his father to study the industry, and while there visited all of the larger engineering works. In 1880 he entered the Portland Company's locomotive and marine-engine works as an apprentice. He served his apprenticeship and became a toolmaker and erector for that company, leaving them in 1888 to work for the Sprague Electric Company. During the next two years he acted as superintendent for the Sprague Electric Company, in charge of construction of electric railways in the various parts of the country. In 1890 he went to New Orleans for the New Orleans Electric Company on construction work. In 1892 he joined the construction staff of the Edison General Electric Company and was

employed in building lighting and power plants for them and the Canadian General Electric Company until 1895. In 1895 he joined the staff of the construction department of the Edison Electric Illuminating Company of New York, and in 1898 became superintendent of construction, having charge of all of the construction, which included the new Waterside Station, at that time the largest and most important construction of its kind which had been attempted. In 1906 he became chief engineer of The New York Edison Company in charge of construction and operation, the position he held at the time of his death.

Mr. Sparrow became a member of the Society in 1898 and was an active member, serving on various committees. At the time of his death he was Chairman of the Committee on Standardization of Flanges and Pipe Fittings, and had just finished the completed report on that subject. On February 1, 1918, he was appointed Chairman of the Advisory Board of the Power Test Committee. His work along these lines has been particularly valuable, as his long experience, trained judgment and personal influence insured the reconcilation of conflicting interests.

John Porterfield Sparrow

In the Association of Edison Illuminating Companies he was a member of the Committee on Steam Plants from 1906 up to the present time, and was chairman in 1910, 1912 and 1913. In this work his most valuable contributions were those in connection with coal testing and burning. Before the Edison Association he presented a number of papers on boiler-plant problems.

In the National Electric Light Association he was a member of the Committee on Prime Movers for a number of years, and was a frequent contributor to the Question Box.

Shortly after the United States entered the war he made a number of tests for the Naval Consulting Board in connection with smoke abatement on ships as a protection against submarines.

Mr. Sparrow's hobbies were largely of an engineering character. In photography his work as an amateur rivaled many professionals, and he was one of the first to take up color photography. Microscopy, as a result of his early training, was always one of his chief aids and his work on the photomicrography of lamp filaments is well known. In later years he turned to metallography in connection with the ever-present subject of the corrosion of condenser tubes, and assisted in the settling of important questions of heat treatment in the manufacture of this material. His knowledge of physical science was fundamental and he was an adept in the mechanical handling and manipulation which is a necessity in research work of this kind.

Mr. Sparrow had a charming personality and his optimistic temperament, uniform courtesy and entire absence of contentiousness endeared him to a host of friends. He was held in affectionate regard by the officials of The New York Edison Company, to whom his passing away comes as a personal loss.

FRANCIS E. GALLOUPE

Francis E. Galloupe was born in Lynn, Mass., on October 3, 1855. He attended the high school in Lynn and later the Massachusetts Institute of Technology at Boston, where he took the course in mechanical engineering and received his degree in 1876.

Upon graduation he was connected with the Rhode Island Locomotive Works for about two years and spent approximately the same time with the Baldwin Locomotive Works and with the Brooks Locomotive Works. The next two or three years he devoted to the design of rolling stock for the proposed Meigs Railroad. Following this period, he was engaged in the real-estate business. He was interested in developing and redeveloping properties and handled some very important transactions along this line. He possessed an unusually complete system of recording engineering information.

Mr. Galloupe was a charter member of the Society. He died in Boston, January 5, 1918.

JOSEPH FREDERIC KLEIN

Joseph Frederic Klein was born in Paris, France, on October 10, 1849. His parents were Huguenots and came to America when he was two and a half years old. They first settled in Bridgeport, Conn., where he attended the public schools, and moved to New Haven in 1858, where he attended the Eaton Grammar School. After finishing his common-school education he was employed as a machinist in the New Haven shops. Later, in 1866, he attended the famous military school of Gen. William H. Russell, which was also a college preparatory school. He was employed by Sargent & Co. and the W. & E. T. Fitch Co. as salesman and shipping clerk, always studying during his spare moments, as he was determined to get a college education.

His studious disposition won him many friends, among whom was the distinguished Prof. Willard J. Gibbs, of Yale University, who took a personal interest in him and through whose influence he decided to enter Sheffield Scientific School of Yale University. This he did in 1868, taking the course in mechanical engineering, then called dynamic engineering, and being graduated with the degree of Ph.B. in 1871. One of his classmates was Mansfield Merriman, afterward his associate at Lehigh University as professor of civil engineering. He was appointed the first instructor of the first evening school started in New Haven in 1868.

From 1871 to 1873 he did experimental work for Prof. W. P. Trowbridge of Yale and others. He also took a graduate course in mechanical engineering, receiving the degree of D. E. (Dynamic Engineer) at Sheffield in 1873. He entered the employ of Colt's Armory, Hartford, Conn., in 1873, first as draftsman and finally as assistant to the chief engineer, Mr. Charles B. Richards, that company being engaged at the time on the work connected with the heating and ventilating system of the (then) new State Capitol at Hartford. Mr. Richards, the inventor of the Richards steam-engine indicator, later became chief engineer of the Southwark Foundry and Machine Co., of Philadelphia, and subsequently professor of mechanical engineering at Yale University. Professor Klein was in the employ of Colt's from 1873 to 1877.

In 1877 Professor Klein returned to Sheffield Scientific School as instructor in mechanical engineering, being the assistant in this department of the late Prof. A. Jay DuBois. In the fall of 1881 he was called to Lehigh University to establish and develop a course in mechanical engineering, and was connected with that institution up to the time of his death. In 1887 to 1888 he was secretary of the faculty. In addition to his duties as head of the mechanical-engineering department he was appointed dean of the faculty in 1907, which additional work he has performed with distinction. From February to April, 1910, he was acting president of the University.

Professor Klein's published books are: Mechanical Technology of Machine Construction, 1884; Elements of Machine Design, 1889; Table of Coördinates for Laying Out Accurate Profiles of Gear Teeth, 1889; The Design of a High-Speed Steam Engine, 1892; and The Physical Significance of Entropy or of the Second Law, 1910. Also the following translations from the German:

Weisbach-Hertmann's Mechanics of Machinery of Transmission, 1883; Zeuner's Treatise on Valve Gears, 1884; and Zeuner's Technical Thermodynamics, 1907. He spent a number of years in researches on Dynamics of the Shaft Governor, intending to issue a work on Flywheels and Governors; this was never completed, although a part of the results of his investigations are in use in the mechanical-engineering course in Lehigh. He also made extensive researches in Kinematics of Machinery. His magazine articles are: Absolute Zero of Temperature, *Van Nostrand's Engineering Magazine*, April, 1880, Vol. xxxii; Concerning $(T_1—T_0)/T_1$ or the Limit of Efficiency of Heat Engines, *Journal of The Franklin*

JOSEPH FREDERIC KLEIN

Institute, March-April, 1879; Table and Diagram for Determining the Diameter of Speed Cones when Connected by an Open Belt of Constant Length, *Journal of The Franklin Institute*, May, 1880; Cone Pulley Diameters, No. 2, *American Machinist*, October 22, 1881; The Law of Proportional Resistance, *Journal of Engineering Society of Lehigh University*, November, 1889; and New Construction of the Force of Inertia of Connecting Rods and Couplers, and Construction of the Pressures on Their Pins, *Journal of The Franklin Institute*, September-October, 1891.

With Mr. L. P. Breckenridge, then his assistant at Lehigh University, now professor of mechanical engineering at Sheffield Scientific School of Yale University, he conducted a series of tests for the Lehigh Valley Road during the summer of (probably) 1888. Among other purposes, the tests were to determine the relative performance value of three different types of locomotive valves, the plain slide valve, the Allen-Richardson balance valve and the piston valve. Incidentally measurements were made of the exact length of the road, and they showed the official record to be a half mile in error.

Professor Klein was elected to membership in the Society in 1881, one year after its organization, and in 1907, on the occasion of the celebration of his twenty-fifth anniversary at Lehigh, he was presented by the alumni of his department of the University with a life membership in the Society. He was an honorary member of Tau Beta Pi. He died on February 11, 1918.

WILLIAM BURNHAM

William Burnham was born in Philadelphia on March 20, 1846. He was educated in private schools in Philadelphia and Allentown, Pa., and at the Lawrence Scientific School, Cambridge, Mass. After spending some years in the employ of the Baldwin Locomotive Works, in 1871 he became assignee for William Butcher, who first manufactured steel locomotive tires in the United States. When this business was reorganized as the Standard Steel Works, he was made secretary and treasurer, subsequently becoming chairman of the board. He was also a director of the Baldwin Locomotive Works.

Mr. Burnham was a member of a number of clubs. He was president of the Pennsylvania Working Home for Blind Men. He became an associate of the Society in 1888. He died on February 25, 1918.

GEORGE SUNTER POWER

George S. Power was born on May 17, 1870, in Brantford, Ont. He was graduated from the high school in Gaylord, Mich., and later took a five years' course at Cooper Union, New York, three of which were devoted to science and two to architecture.

Upon the completion of his high-school course he acted as principal for three years of a school in Duncan City, Mich. His next position was with the First National Bank of Duluth, Minn., as bookkeeper. About 1893 he left for New York City, where he became superintendent of the J. & J. Morrison Co., plasterers. In 1896 he became connected with the Witherspoon Plaster Mill, where his work consisted in the designing and building of labor-saving devices. In the following years he was associated with the Jackson Architectural Iron Works in designing and drafting; the Manhattan Concrete Co. in figuring and estimating; V. Dorne Sons, New York, as superintendent and estimator, and with the Rock Plaster Co., New York and Hoboken, as superintendent. In 1903 he was employed by the Robins Conveyor Belt Co. to design conveyor machinery; he also supervised the erection of a new plant for the company at Passaic, N. J. In 1903 he became identified with the U. S. Gypsum Co., Chicago, Ill., where his work consisted of designing and building new and remodeling old

GEORGE SUNTER POWER

gypsum mills. From 1905 to 1916 Mr. Power was associated with the firm of Wickes Brothers, Saginaw, Mich., where he held successively the positions of draftsman, designer of new machines, superintendent, and general manager of the rock-drill department. For the past fourteen months, up to the time of his death, he was with the Bayonne Steel Casting Co., Bayonne, N. J., as construction engineer and purchasing agent.

Mr. Power became a member of the Society in 1916. He died on January 14, 1918.

THOMAS FAWCUS

Thomas Fawcus was born in April, 1866, in Bedlington, England. He was graduated from the College of Science and Art, Newcastle-on-Tyne, England. He served his apprenticeship with

Black, Hawthorne & Co., Gateshead, England, locomotive, marine and stationary-engine builders.

He came to this country in 1888, locating in Birmingham, Ala., and was associated with various manufacturing firms in the southern states until 1893. At that time he became assistant to the superintendent of the Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa. About two years later he accepted the position of assistant superintendent of the steel plant of the Anderson-Dupuy Co., resigning in 1897 to become superintendent of the R. D. Nuttall Co., Pittsburgh, Pa.

Wishing to control his own business he organized and established in 1900 the Fawcus Machine Co. at Pittsburgh, manufacturing gears and special machinery and particularly herringbone-gear drives.

Mr. Fawcus was responsible for many inventions, the most notable of which are the machines for cutting herringbone gears, which he started to design and develop in 1912. These machines were patented in the United States and foreign countries.

Mr. Fawcus took an active interest in civic affairs and was a member of the Chamber of Commerce and of the Manufacturers' Association of Pittsburgh. He was also a member of the Engineers' Society of Western Pennsylvania. He became a member of our Society in 1913. He died on January 22, 1918.

ARTHUR IRVING JACOBS

Arthur I. Jacobs was born in Hebron, Conn., in 1858. His educational advantages were meager during his boyhood and after his ninth year his schooling was limited to a short period in the winter. He worked with his father in mechanical lines until he attained his majority, when he secured employment in the Knowles Loom Works, Worcester, Mass. His mechanical bent

Thomas Fawcus

soon displayed itself and in a short time he made great improvements in the manufacturing methods of making harness chains for looms. He remained with this firm until 1887, during which period he invented and built a book-sewing machine of which several were purchased by Boston bookbinders. The Smyth Manufacturing Co., Hartford, Conn., which also manufactured such machines, became interested in his inventions, purchased his patents and engaged him to go to Hartford and he remained with them until 1901. During this period he invented and developed several machines for bookbinding; among these were two machines for making book covers which marked a great advance over methods which had been employed.

In 1902 he invented an improved drill chuck which he patented in the fall of that year. The following year the Jacobs Manufacturing Company was incorporated and has expanded from a small business to a large and active concern, of which he was president at the time of his death.

Mr. Jacobs became a member of the Society in 1913. He died on February 16, 1918.

LUIS G. MARQUINA

Luis G. Marquina was born in 1871 in Lima, Peru. He was educated in the Colegio de Guadalupe, Lima, and received his engineering degree in 1893 from the Escuela de Ingenieros, Lima.

His practical experience in general engineering was gained in

Arthur Irving Jacobs

the Casapalca and Rayo Smelting Works and with the firm of Backus & Johnston. From 1893 to 1897 he was in the drafting room of the Peruvian Corporation, Ltd., at Lobos Island. From 1897 to 1902 he was with the same company as superintendent and engineer of the Pascamayo Railroad. For the next four years he was general superintendent and engineer of the Eten Railroad. About 1907 he returned to the Peruvian Corporation and at the time of his death was general superintendent and engineer of that company.

Mr. Marquina became a member of the Society in 1906. He died on June 18, 1917.

FREDERICK W. SNYDER

Frederick W. Snyder was born on June 18, 1884, in Philadelphia, Pa. He was educated in the public schools and later attended the Williamson Free School of Mechanical Trades, from which he was graduated in 1904.

Upon his graduation he was employed as machinist in the Frankford Arsenal, Philadelphia, where he remained for over a year and a half. His next position was with the Buckhorn Portland Cement Co. as draftsman, but after a brief period in this capacity he was appointed assistant mechanical engineer of the plant. In 1908 he became associated with the Baldwin Locomotive Works, Philadelphia, Pa. His work there was in the drafting room and consisted of detailing and designing electric mine locomotives. After a year and a half he resigned to take a position with the Miller Lock Co., Frankford, Philadelphia, Pa., where he designed tool-room jigs and fixtures, blanking and bending dies, etc. In April, 1910, he became an instructor in the Williamson Free School of Mechanical Trades, Delaware County, Pa. At the time of his death he had charge of the classes in strength of materials and in machine-shop practice.

Mr. Snyder became an associate-member of the Society in 1916. He died on January 29, 1918.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER MAY 10

Below is the list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 256.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by May 10, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about June 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Arizona

RORK, Charles E., Chief Draftsman, Phelps Dodge Corporation, Douglas

California

CARSE, Herbert E., Lieutenant, U. S. Naval Reserve Training Camp, San Pedro

STROMGREN, Charles D., Superintendent, Y. M. C. A. Automobile and Mechanical School, Los Angeles

WHITE, Ernest M., Consulting Mechanical Engineer, Los Angeles

Colorado

NEILL, William A., Chief Mechanical Engineer, The Dorr Co., Denver

Connecticut

BLAKESLEE, Howard R., Asst. Master Mechanic, The American Brass Co., Waterbury

BRAWN, Elwin D., Designer, Bilton Machine Tool Co., Bridgeport

CUMMINS, Norman W., Chief Engineer and Director, The Bassick Co., Bridgeport

HANSON, Henry, Superintendent of Machine Dept., Wilcox, Crittenden & Co., Inc., Middletown

LINABURY, John E., Chief Engineer, Bristol Brass Co., Bristol

MASON PARRY, Edmund J., Directing Inspector, Hartford Steam Boiler Insp. & Ins. Co., Hartford

MOORE, Frederick T., Assistant Works Manager, Colt's Patent Fire Arms Mfg. Co., Hartford

Delaware

SHAFFER, Charles A., Engineer, Du Pont Nitrate Company, Wilmington

District of Columbia

GOODWIN, Percy F., Captain, Engineers, U. S. R. General Engineer Depot, U. S. Army, Washington

PORTER, Minott E., Principal Examiner, Steam Engines and Boilers, U. S. Patent Office, Washington

STEINMETZ, Charles M., Engineer, Washington

Georgia

HARRISON, Nathaniel C., General Superintendent, Atlantic Steel Co., Atlanta

Idaho

COATES, Arthur B., Assistant in Mechanical Engineering, University of Idaho, Moscow

ORR, Burton S., Associate Professor of Mechanical Engineering, University of Idaho, Moscow

Illinois

CORMACK, George, Master Mechanic, Appleton Mfg. Co., Batavia

FREDE, Charles F., Manager of Engineering, Commonwealth Steel Co., Granite City

KIMBALL, Raymond W., Boiler Room Engineer, Commonwealth Edison Co., Chicago

MOREY, William E., Mechanical Engineer, Rodger Ballast Car Co., Chicago

RAUNICK, Ernest J. M., Master Mechanic, By-Products Coke Corp., Chicago

STARKEY, D. W., Chief Draftsman, Griffin Wheel Co., Chicago

STOLL, Clarence G., Technical Superintendent, Western Electric Co., Chicago

WOODFIELD, George E., Sr., Superintendent, Flottorp Mfg. Co., Chicago

Indiana

BROSSMANN, Charles, Consulting Engineer, Indianapoils

MARSH, Harry B., President and Manager, Marsh Mfg. Co., Vincennes

MULLINS, Thomas C., General Manager, Sunlight Coal Co. & Ohio Valley Coal Co., Boonville

OTT, Albert J., President, Ott Grinder Co., Indianapolis

ROBBINS, Elmer J., Layout work, Engineering Dept., Dodge Mfg. Co., Mishawaka

Maine

CASWELL, Wilfred H., Master Mechanic, Sandy River & Rangeley Lakes Railroad, Phillips

DELANY, Edwin H., Naval Inspector of Machinery, Bath Iron Works, Bath

HANSON, Albert J., Principal Assistant Engineer, The Moulton Engineering Corp., Portland

Maryland

HUBER, Charles J., Mechanical Engineer, The Flynn & Emrich Co., Baltimore

Massachusetts

ACHILLE, Charles E., Branch Manager and Sales Engineer, Mathews Gravity Carrier Co. of Ellwood City, Pa., Boston

BARTLETT, Henry B., Chief Engineer, B. F. Perkins & Son, Inc., Holyoke

BARTON, George S., President and Treasurer, Rice, Barton & Fales M. & I. Co., Worcester

BEACH, Charles L., Manager, The Hoffecker Co., Boston

BENNETT, John C., Works Manager, Hampden Corundum Wheel Co., Springfield

BROADHURST, Frank S., Treasurer, Starkweather & Broadhurst, Inc., Boston

BURBANK, Albion P. W., Sales Engineer, B. F. Sturtevant Co., Boston

COLBY, Llewellyn A., Inspector, General Electric Co., Pittsfield

EBELHARE, William H., Industrial Engineering, Robert T. Pollock Co., Boston

GALUSHA, Albert L., In charge of Gas Producer Dept., Nelson Blowers & Furnace Co., Boston

GOULD, Henry G., Comptroller and Director, The Graton & Knight Mfg. Co., Worcester

KNOLLMEYER, Louis F., Chief Inspector, General Electric Co., Pittsfield

LEWTHWAITE, Alfred L., Mechanical Engineer, General Electric Co., Pittsfield

MEEK, Alden R., Sales Engineer, Westinghouse Elec. & Mfg. Co., Boston

SCANLON, Edward J., Chief Inspector, Boston Inspection Division, Maryland Casualty Co. of Baltimore, Md., Boston

SCHAUFUS, Hugh Albert, Production Manager, Metz Company, Waltham

SEWELL, Henry R., Manager Power Apparatus Dept., B. F. Sturtevant Co., Boston

TAYLOR, Clarence G., Draftsman in Engineering Dept. of U. S. Armory, Springfield

Michigan

BOSTAPH, Harvey P., Chief Engineer, Bostaph Engineering Co., Detroit

HOLDRIDGE, Clarence A., Factory Manager, Metalwood Mfg. Co., Detroit

KILPATRICK, William J., Factory Manager of Burroughs Adding Machine Co., Detroit

THOMAS, George J., Chief Engineer and Superintendent, Duplex Truck Co., Lansing

Missouri

QUINN, Everett J., Inspector Electrical and Mechanical Engineering, Kansas City

ROBINSON, Arthur D., Engineer, Monsanto Chemical Works, St. Louis

SCOTT, Lewis L., Chief Engineer, Scott Drill Company, St. Louis

Nebraska

RASMUSEN, Jesse E., Associate Professor, University of Nebraska, Lincoln

New Jersey

ENKE, George P., Insurance Engineer, James E. Garabrant & Co., Newark

GARSON, Thorvald N., Superintendent of Construction, The Singer Manufacturing Co., Elizabethport

RUSS, Charles W., Manager, Armstrong Cork Co., Camden Plant, Camden

WICKHAM, JAMES S., General Foreman, Crucible Steel Co. of America, Ordnance Dept., Harrison

New York

BARNUM, E. S., Editorial Work, G. M. Basford Company, New York
BENDURE, JAMES A., Sales Engineer, American District Steam Co., N. Tonawanda
COOK, SAMUEL, Air Brake Foreman, Van Nest Elec. Shops, N. Y., N. H. & H. R. R. Co., Van Nest, New York
DENISON, GRISWOLD, Engineer, Moses, Pope & Trainer, Inc., New York
DORNIN, ALEXANDER L., Engineer, Theo. E. Ferris, New York
EBY, EARL E., Asst. Manager, Industrial Bearings Div., Hyatt Roller Bearing Co., New York
ELLIOT, JAMES A., Assistant Engineer, Mathieson Alkali Works, Inc., Niagara Falls
FLECKENSTEIN, ALFRED C., Office Manager and Cost Accountant, Richmond Radiator Co., New York
FLEISHER, WALTER L., President, W. L. Fleisher & Co., Inc., New York
GRONBECH, CHRISTIAN E. A., Superintendent & Assistant Factory Manager, C. J. Tagliabue Mfg. Co., Brooklyn
HARD, MALCOLM, Mechanical Engineer, Nathan Manufacturing Co., Flushing, New York
HARRISON, GEORGE C., Industrial Engineer and Chartered Accountant, New York
HAVENS, WILLIAM W., Assistant Engineer, Liquid Air Division, Engineering Dept., Air Nitrates Corporation, New York
HELMER, NICHOLAS A., Consulting Engineer, Miranda Sugar Co., New York
HOOVER, A. PEARSON, Consulting Engineer, Goodrich, Hoover & Bennett, New York
HOPKINS, WILLIAM P., With C. E. Knoeppel & Co., New York
JENSEN, ARTHUR R., Instructor of Physics and Applied Electricity, Hebrew Technical Inst., New York
KIRSCH, GEORGE H., Member Committee of Examiners, Naval Consulting Board, New York
LATTING, JOHN W., Farming, Werah Farms, Inc., Locust Valley
MORROW, ALEXANDER P., President and Manager, Willys-Morrow Co., Elmira
NORDFORS, CONRAD, Contracting Engineer, Wood Newspaper Machinery Corp., New York
OLSON, HAROLD M., Mechanical Engineer, The Permutit Co., New York
O'ROURKE, GEORGE A., Chief Engineer, State Industrial Commission, Bureau of Boilers & Explosives, Albany
PAGE JULIAN D., Chief Draftsman, Perin & Marshall, New York
RANK, HOMER L., Asst. Manager, New York Office, Mead-Morrison Mfg. Co. of Boston, New York
ROTHWELL, COURTENAY R., President, Plant Engineering and Equipment Co., New York
RYTHER, GEORGE D., President, Ryther & Pringle Company, Carthage
SCHUYLER, LESLIE J., Production Manager, Porter-Cable Machine Co., Syracuse
SHOREY, JOHN A., Engineer Specialist, General Electric Co., New York
UEHLING, F. F., Combustion Engineer, also General Manager Uehling Instrument Co., New York
UPDIKE, DAVID M., Assistant Superintendent, Department of Buildings and Grounds, Columbia University, New York

Ohio

JOHANNESMEYER, CHARLES G., Chief Mechanical Engineer, The Liberty Machine Tool Co., Hamilton
KAARBO, AGNAR, Mechanical Engineer, Hydraulic Pressed Steel Co., Cleveland
KAHN, BERTRAND B., Works Engineer, The Estate Stove Co., Hamilton
PEARSON, MORRIS A., Chief Engineer, Turner Vaughn & Taylor Co., Cuyahoga Falls
SPARKS, A. F., General Manager and Chief Engineer, The James Leffel & Co., Springfield
TOWNSEND, THEODORE A., Chief Draftsman, McGraw Fire & Rubber Co., East Palestine
WITKER, CHARLES J., Mechanical Engineer, Baker Brothers, Toledo

Oklahoma

DRYDEN, RAYMOND P., Draftsman, Gosden & Co., West Tulsa

Pennsylvania

CAMPBELL, JAMES R., Mechanical Engineer, Baldwin Locomotive Works, Philadelphia
FOLTZ, THOMAS F., Mechanical Engineer, Pennsylvania Dept. of Labor & Industry, Harrisburg
GEE, NORMAN E., Assistant Foreman, Pennsylvania Railroad, M. E. Office, Altoona
GROAT, BENJAMIN F., Consulting Engineer, Pittsburgh
GROW, JOSEPH A., Mechanical Engineer, Blaisdell Machinery Co., Bradford
HARRIS, EDSON S., President, Philadelphia Steel Products Co., Philadelphia
HOOD, MARVIN C., Manager Employment Department, Chester Shipbuilding Co., Chester
JOHNSON, JOHN B., Superintendent of Power and Machinery Erection, Wm. Gordon Corp., Bristol
LARKIN, WILLIAM H., JR., Assistant Manager and Treasurer, Larkin & Co., Butler
MIKAELSON, ERIL W., Chief Engineer, Treadwell Engineering Co., Easton
RUSH, LEO E., Planning and Production Engineer, Bethlehem Steel Co., Bethlehem
SCHMID, WERNER E., Mechanical Engineer, Dravo-Doyle Co., Pittsburgh
SKINKLE, WILLIAM B., Assistant Chief Mechanical Engineer, Homestead Steel Works of Carnegie Steel Co., McKees Rocks
STAMETS, WILLIAM K., Machine Tool Dealer, Pittsburgh
STEVENSON, ARTHUR J., Watch Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh
STUDLEY, GIDEON, JR., Engineer, Condenser Dept., Westinghouse Elec. & Mfg. Co., Machine Works, East Pittsburgh
THOMPSON, JOHN L., Chief Engineer, The Koppers Co., Pittsburgh

Rhode Island

FLICK, LORENZ, Experimental Engineer at Sayles Finishing Plants, Saylesville
HIRD, GEORGE W., Foreman, Tool Department, Woonsocket Machine & Press Co., Woonsocket
TILLINGHAST, WALLACE E., Managing Owner of the Mass. Steam Specialty Co., Auburn

Tennessee

MURRIAN, WILLIAM S., Superintendent of Motive Power, Southern Ry., Knoxville

Texas

GLASGOW, JOHN B., Assistant Construction Engineer, Gulf Refining Co., Port Arthur

Utah

SECKELS, LOUIS J., Engineering Salesman, F. C. Richmond Machinery Co., Salt Lake City

Virginia

HAMMERSTROM, WILLIAM G., General Superintendent, Lynchburg Foundry Co., Lynchburg

Vermont

PAINE, WALTER H., Master Mechanic, Boutwell, Milne & Varnum Co., Graniteville

Wisconsin

BAIR, EDWARD H., Consulting and Sales Engineer, Fairbanks-Morse Co., Milwaukee

Canada

CANTELL, MARK T., Consulting Engineer, Winnipeg
NORRIS, EDWIN R., Master Mechanic, Algoma Steel Corporation, Sault Ste. Marie
WHITE, ALBERT F., General Superintendent, Marsh & Henthorn, Belleville, Ontario

Canal Zone

AUTEN, WILLIAM J., Mechanical Engineer, Mechanical Div. P.C., Balboa

Cuba

SNODGRASS, WILLIAM, Engineer, Honolulu Iron Works Co., Havana
WATERMAN, HENRY J., Chief Engineer, Central Stewart, Cuba Cane Sugar Corp., Stewart, Camaguey

Hawaii

McKAY, WILLIAM, Marine Superintendent, Inter Island Steam Navigation Co., Ltd., Honolulu
SIMPSON, ALFRED M., Superintendent, Honolulu Iron Works Co., Honolulu

Japan

HIRANO, T., Adviser of Kobe Steel Works, Kobe

Scotland

GIBSON, ARNOLD H., University Professor of Engineering, University of St. Andrews, Dundee

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE MEMBER

Alabama

FEAR, FRANK G., Draftsman, Tennessee Coal Iron & R. R. Co., Ensley

Arizona

DUNNING, CHARLES H., Manager, Big Pine Consolidated Mining Co., Prescott

California

BLANCHARD, WALTER J., Assistant Chief Engineer, California & Hawaiian Sugar Refining Co., Crockett

Connecticut

BUCHANAN, WILLIAM C., Superintendent, Steel Works, Rolling Mills, American Tube & Stamping Co., Bridgeport
HONIG, FRANK, Designer of Special Machinery, The Bristol Brass Co., Bristol
MADDISON, WALTER F., Instructor, State Trade Education Shop, Bridgeport

District of Columbia

KARTSHER, HARRY S., Gage Designer, Engineering Bureau, U. S. Ordnance Dept.,

Massachusetts

KING, VERNON C., Chief Draftsman, Spencer Wire Co., Worcester
POLLEY, ALVIN H., Chief Draftsman, Brown Engine & Machine Co., Fitchburg

Minnesota

THAYER, PAUL W., Mechanical Engineer, Williams Bros. Boiler & Mfg. Co., Minneapolis

Missouri

GEORGE, Ralph D., Assistant Engineer, E. M. Stevens & Co., Consulting Engineers, Kansas City

New Jersey

FRAMBACH, Frederick S., Sales Engineer, Hyatt Roller Bearing Co., Newark

SLEEPER, William A., Assistant to President, Brighton Mills, Passaic

New York

BENSAMON, Edmond, Manager Refining Plant, American Chicle Co., Long Island City

MIANO, Nicholas J., Mechanical Engineer, Universal Fixture Corp., New York

POSTNIKOFF, Alexander A., Chief Inspector Russian Mission of Ways of Communication, New York

WALTERS, V. Edgar, Night Superintendent Savage Arms Corp., Utica

Ohio

McGILL, Minto, Draftsman, The Alliance Machine Co., Alliance

Rhode Island

FOLEY, Patrick H., Foreman, C. B. Cottrell & Sons Co., Westerly

Canada

BARRETT, Karl E., Superintendent and Chief Engineer, E. & T. Fairbanks, Ltd., Sherbrooke

FOZARD, Leonard G., Master Mechanic, The Marconi Wireless Telegraph Co., Montreal

JOYCE, Walter E., Engineer of Design, Mount Royal Tunnel & Terminal Co., Ltd., Montreal

MURPHY, Peter, Chief Draftsman, Marconi Wireless Telegraph Co., Montreal

FOR CONSIDERATION AS ASSOCIATE MEMBER OR JUNIOR

California

DOYLE, Frederick F., Engineer, Midway Gas Co., Taft

Colorado

MILLER, Albert F., Designing Engineer, Peters Machinery Co., Denver

Connecticut

BUCHANAN, David D., Night Superintendent, American Tube & Stamping Co., Bridgeport

COFFIN, Grange S., Mechanical Engineer, Remington Arms U. M. C. Co., Bridgeport

WEIDER, Arthur A., Installation, Industrial Engineering Staff, Winchester Repeating Arms Co., New Haven

Delaware

SCHNEIDER, Franz K., Assistant Chief Engineer, The Krebs Pigment & Chemical Co., Newport

District of Colombia

CHAPIN, William C., Assistant Inspector Weights and Measures, Bureau of Standards

HEDSTROM, Ernest R., Lieutenant, Engineering Bureau, U. S. Ordnance Dept.

WEISS, Erwin A., Ordnance Sergeant, Engineering Bureau, Motor Section.

Indiana

HUFF, Aaron B., Special Apprentice, Pennsylvania R. R. Co., Fort Wayne

Maryland

RYLANDER, Paul N., Aeroplane Inspector, U. S. Navy, Baltimore

Massachusetts

CARTER, Irving E., Machinist Mate 2nd Class, U. S. Naval Reserve, District No. 1, Boston

FOISY, George A., Designing Engineer, U. S. Cartridge Co., Lowell

PAINCHAUD, Phillip A., Inspector of Ordnance, U. S. Army, C. H. Cowdrey Machine Works, Fitchburg

PRATT, Winthrop S., Manufacturing Manager, Heald Machine Co., Greendale

SMITH, Raymond E., Assistant Engineer and Draftsman, Springfield Armory, Springfield

SPARROW, Stanwood W., Mechanical Engineer, Robert T. Pollock Co., Boston

Michigan

HOLMBERG, Abner W., Instructor Foundry Practice, Ironwood High School, Ironwood

Missouri

JOHNSEN, Peder, Mechanical Engineer, Missouri Cobalt Co., Fredericktown

New Jersey

ACKERMANN, William H., Mechanical and Production Engineer, Bayonne Bolt & Nut Co., Bayonne

KOHLBUSCH, Arthur H., Assistant Superintendent Construction, Public Service Electric Co., Newark

New York

CASE, Lynn B., Chief Engineer, Standard Wall Paper Co., Hudson Falls

LEWIS, William J., Jr., Assistant Manager Engineering Department, Shipley Construction & Supply Co., Brooklyn

McINTYRE, James J., Publicity Engineer, Machinery, New York

NEEL, Robert W., Chief Engineer, Erie Pump & Engine Works, Medina

OSMENA, Mariano, Draftsman, Combustion Engineering Corp., New York

PULSCHEN, Henry G., Draftsman, J. G. White Engineering Corp., New York

RABBE, Hellik, Draftsman, Kerr Turbine Co., Wellsville

RIDDLE, George G., Engineering Department, Ingersoll Rand Co., Painted Post

SYSKA, Adolph G., Assistant Engineer, New York Central R. R., New York

SWAIN, Wilbur A., Salesman, Jenkins Bros., New York

Pennsylvania

DOWNS, Leslie B., Assistant Chief Engineer, Epping-Carpenter Pump Co., Pittsburgh

FISHER, Herman A., Assistant to Plant Engineer, Chester Shipbuilding Co., Chester

GUTEKUNST, Leonard, Mechanical Engineer, De Long Hook & Eye Co., Philadelphia

KEENAN, William J., Draftsman, American International Shipbuilding Corp., Philadelphia

KIRKPATRICK, W. Alton, C. H. Wheeler Mfg. Co., Philadelphia

KOHN, Louis, Mechanical Engineer, Dravo Contracting Co., Pittsburgh

MORGAN, David W. R., Engineer, Condenser Department, Westinghouse Elec. & Mfg. Co., E. Pittsburgh

PRINGLE, Harry C., Master Mechanic, Franklin Works, Cambria Steel Co., Johnstown

SENIOR, John H., Sales Engineer, Smith & Furbush Machine Co., Philadelphia

Rhode Island

SHERWIN, LeRoy M., Mechanical Engineer, Brown & Sharpe Mfg. Co., Providence

Virginia

HORNE, Caleb L., Boiler Engineer, E. I. du Pont de Nemours & Co., City Point

Washington

TRACK, Frank A., Naval Architect & Marine Engineer, Sanderson & Porter, Shipyard, Raymond

FOR CONSIDERATION AS JUNIOR

Connecticut

BUTLER, Frank T., with 19th Engineers, U. S. Army, formerly with The Bristol Co., Waterbury

HORGAN, Daniel F., Naval Sub-Inspector of Ordnance, Office of Naval Inspector of Ordnance, Bridgeport

McCARTY, Robert P., Tool Designer, Colt's Patent Fire Arms Mfg. Co., Hartford

Delaware

BENST, Cecil J., Engineering Draftsman, E. I. du Pont de Nemours & Co., Wilmington

DOAR, E. Marion, Jr., Draftsman, Engineering Department, E. I. du Pont de Nemours & Co., Wilmington

Illinois

DUNDAS, William A., Field Engineer, Sherwin, Williams Co., Chicago

VAN DEVENTER, Frank M., Assistant Operating Engineer, Illinois Traction System, Peoria

Louisiana

MITCHELL, Grover L., Instructor, Louisiana Industrial Institute, Ruston

Maryland

STIERHOFF, George C., Engine Designer and Power Engineer, Riter-Conley Mfg. Co., Fairfield

Massachusetts

BEATTIE, Challen M., Mechanical Draftsman, Bethlehem Shipbuilding Corp., Ltd., Fore River Plant, Quincy

MENDELSOHN, Louis E., Engineer, Western Electric Co., Inc., Boston

Michigan

CAMERON, Hugh M., Chief Engine Draftsman, Saginaw Shipbuilding Co., Saginaw

Minnesota

ABERNETHY, Alfred A., Designer, Minneapolis Steel & Machinery Co., Minneapolis

Missouri

ANGEVINE, Leland C., Superintendent Hydroelectric Plant, Burns & McDonnell, Kansas City

ROYSE, Iram O., Instructor in Machine Drafting, David Ranken, Jr., School of Mechanical Trades, St. Louis

New Hampshire

CHICK, George E., Partner, John F. Chick & Son, Lumber Manufacturers, Silver Lake

GRAY, Frank A., Purchasing Agent, The Lebanon Machine Co., Lebanon

New Jersey

KING, Warren G., with Aeromarine Plane & Motor Co., Keyport

OBERLE, John H., Checker and Contract Analyzer, Babcock & Wilcox Co., Bayonne

ROTHOWITZ, Harry S., Production Engineer, Babcock & Wilcox Co., Bayonne

RUSCH, Olaf, Designer, Babcock & Wilcox Co., Bayonne.

New York

BOIES, Harry B., Inspector of Airplanes and Airplane Engines, Signal Service at Large, Buffalo

BROOKS, Frederick A., Airplane Designer, Curtiss Aeroplane & Motor Corp., Buffalo
CONWAY, John J., Testing Engineer, Alberger Pump & Condenser Co., Newburgh
DANKS, Roy L., Time Study Engineer, Winchester Repeating Arms Co., New York
DUNN, William K., Long Lines Engineering Dept., American Telephone & Telegraph Co., New York
GOSSELIN, Edward N., Industrial Engineer, Miller, Franklin, Basset & Co., New York
HAUSER, George H., Jr., Junior Engineer, The Arnold Co., Brooklyn
HILL, Herbert M., Manager, United States Machine Mfg. Co., New York
MORGAN, Albert H., Engineering Assistant, Western Union Telegraph Co., New York
NAUMANN, Carl, Factory Representative, Hannifin Mfg. Co., Syracuse
PERKINS, Donald L., Leading Man, Federal Shipbuilding Co., New York
RUNYON, Howard J., Jr., Sales Engineer, United Filters Corp., Brooklyn
SCHLEIFER, Arthur, Assistant Engineer, Interborough Rapid Transit Co., New York
STAMER, Frank R., Senior Student Mechanical Engineering, Brooklyn Polytechnic Institute, and Assistant to Dr. A. A. Adler, Consulting Engineer, Brooklyn
TUOMEY, Thomas D., Secretary and Manager, Sanitary Mechanical Specialty Co., New York

Ohio

ALLISON, John R., 2nd Lieutenant, Engineer Reserve Corps, U. S. Army, Cleveland
CHASE, Vernon B., Sales Engineer, The Acklin Stamping Co., Toledo
PHILPOT, Norbourn E., Testing Engineer, The Youngstown Sheet & Tube Co., Youngstown
ROGERS, J. Frank, Engineer in Charge Gas Producer & Furnace Dept., The Wellman-Seaver-Morgan Co., Cleveland
SPRONG, Edward A., Jr., Head of Production Department, Niles Tool Works, Hamilton

Pennsylvania

FLYNN, James A., Production Engineer, Blaw-Knox Co., Pittsburgh
HARTSIG, Emory R., Assistant to Resident Engineer, U. S. Shipping Board, Hog Island, Philadelphia
HENDEE, Robert W., Engineer, Midvale Steel & Ordnance Co., Nicetown, Philadelphia

Vermont

JOHNSON, Joseph B., Chief Engineer, Bryant Chucking Grinder Co., Springfield

Virginia

SMITH, Lewis M., Radio Draftsman, U. S. Navy Yard, Norfolk

Wisconsin

SEUTTER, Louis, Assistant Engineer in Forest Products, U. S. Dept. of Agri., Forest Service, Forest Products Laboratory, Madison

Canada

HIGGINSON, Richard H., Superintendent, Monarch Brass Mfg. Co., Ltd., Toronto
LEWIS, Donald, Chief Draftsman, Nova Scotia Steel & Coal Co., Ltd., New Glasgow, N. S.

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

Massachusetts

CHAPMAN, David A., Vice-President, The Dangel Co., Winthrop

New York

DIVINE, Bradford H., President, Divine Brothers Co., Utica

PROMOTION FROM ASSOCIATE-MEMBER

Illinois

MAHER, Eugene E., Contracting Engineer, Lea-Courtenay Co., Chicago

Michigan

ANTON, James E., Assistant Manager of Mfg., Cadillac Motor Car Co., Detroit

Ohio

GRISWOLD, Howard L., Consulting Engineer, Standard Bolt Co., Columbus

Canada

GAINES, Edward C., Engineer, Dominion Bridge Co., Montreal

PROMOTION FROM JUNIOR

District of Columbia

COOMBS, Howard A., Patent Attorney.

Georgia

O'BRIEN, Dennis J., Mechanical Expert, Galena-Signal Oil Co., Atlanta

Promotion from Associate-Member	4
Promotion from Junior	8
Total	270

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

IN forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for The Journal should be in by the twelfth of the month.

GOVERNMENT REQUESTS

AEROPLANE AND MOTOR CORPORATION has available a number of attractive opportunities for technically trained men as equipment, production, maintenance and woodworking engineers, and as high-grade tool and die designers. Younger men are also wanted for planning and routing work in premium department. 2589.

INSPECTORS of airplane metal and wood parts, assemblies, propellers; must be able to read blueprints and use simple instruments.

Inspectors of airplane motors with knowledge of methods of heat-treatment of metals and machine-shop or tool-room experience, preferably on engine parts.

Inspectors of electrical material. Salaries for these civilian positions at the beginning will be from $1200 to $1500 per annum. 2591.

COMMISSIONED OR CIVILIAN SERVICE. Research and development men to bring to stage of commercial production parts made of sheet metal, fabrics, rubber and die castings. Applicants must have personality to secure coöperation of manufacturers in development work along the above lines. Salary $2000 to $2500. 2592.

POSITIONS AVAILABLE

ESTIMATOR for boiler and tank work, gray-iron castings and some machine-shop work. Requires a man of stability and experience. Technical education preferred. Location Buffalo, N. Y. 089-D.

MECHANICAL DRAFTSMAN for general factory work to lay out work of a general character. Familiar with power-plant, steam-heating and electrical equipment. Good opportunity for advancement for right kind of man. Location Newark, N. J. 092-D.

ENGINEERS for Asiatic service, men above draft age up to 37, preferably unmarried but will consider married men. Men with mechanical, electrical, or chemical engineering education, preferably with sales experience. Salary $2000 or more, depending upon ability and experience. 097-D.

TECHNICAL GRADUATE or mechanical engineer for office work in connection with power plants with large manufacturing concern in Western Pennsylvania. Salary at

[illegible] State particulars of education, [illegible] and experience. 099-D.

TECHNICAL GRADUATE or mechanical engineer to enter engineering organization of large stoker company in Western Pennsylvania. Man specialized in combustion science and boiler testing work preferred. State particulars of education, experience, nationality and salary desired. Good opportunity for right man. 0100-D.

CHIEF DRAFTSMAN for large stoker company in Western Pennsylvania. Must be a good designer. Man with experience on stoker work preferred. Good opening for a capable and energetic man. Write stating nationality, age, education, experience, present responsibility and salary expected. 0101-D.

JUNIOR ENGINEER, familiar with heat transfer calculation, in the engineering department of a large steam-specialty manufacturing concern. A graduate engineer with at least two years' outside experience is desired. Location New York. 0102-D.

YOUNG TECHNICAL MAN to assist in sales correspondence and experimental work, primarily as assistant to executive. Prefer man recently graduated from technical school and exempt from military service. Excellent opportunity for growth. Location New York. 013-D.

GRADUATE of technical school with some machine-shop experience and not subject to draft, as assistant to engineer of sales department located in metropolitan district. Excellent opportunity for the right man. Apply by letter, giving full particulars. 0104-D.

MECHANICAL DRAFTSMAN in New York office, preferably one versed in mechanical refrigeration and electrical engineering. 0109-D.

TOOL DESIGNER capable of designing efficient tools for engine manufacture along modern lines. Salary from $100 to $150 a month according to ability. Location Wisconsin. 0110-D.

DESIGNER on outside installation of piping, electric lines and heating mains. Technical graduate preferred. Salary depends on ability. 0111-D.

INSPECTOR on outside installation of piping, electric lines and heating mains. Technical graduate preferred. Salary depends on man. 0112-D.

ENERGETIC YOUNG MECHANICAL ENGINEER exempt from draft, with sales ability, as business developer for an engineering company of New York City specializing in the operation of power plants in buildings. Good salary and share in profits given to the right man. State present salary and qualifications. 0113-D.

SALES MANAGER AND EXECUTIVE to manage long-established, small but high-class and prosperous business in electrical measuring instruments. Must have sales experience, good personality and proven selling ability. Good immediate remuneration and ultimate stock interest to right party. Location New York. 0115-D.

YOUNG MEN, preferably exempt from draft, to train as engineers and salesmen. Preferably technical graduates, bright, alert and of analytic frame of mind. Salary depends on men. Location Massachusetts. 0116-D.

DRAFTSMEN. Two technical graduate mechanical engineers with 6 to 12 months' experience in general mechanical drafting in an industrial plant. Advise salary expected. Location New York State. 0117-D.

SUPERINTENDENT experienced in general machine-shop practice and of good executive ability for shops employing 600 and 700 men. Location Ohio. 0119-D.

POWER ENGINEER experienced in public-service corporation or in power department of large industrial corporation, thoroughly familiar with costs, the economics of power and the technique of power transmission and generation. Man of strong personality who can grow. Require from six to eight years' practical experience after technical training. 0120-D.

SUPERINTENDENT for moderate-sized machine shop making small stampings and cast brass parts. Man with unquestionable record required. Send complete past experience with names of companies where employed and position held with each. Want man experienced in economical manufacture of small parts in quantities and well versed in modern economical production. Location Michigan. 0121-D.

MEN to take charge of construction of marine engines for which contracts have been let to small concern. Location Erie, Pa. 0123-D.

SALESMAN on railway, mining and electrical equipment. Experienced man over 31 required. Knowledge of French preferred. Salary depends on man. Headquarters in China. 0124-D.

MECHANICAL ENGINEER to take charge of engineering department of large paper mill. Man with a technical education and a successful record in the operation and maintenance of power plants and factories and also the handling of men. State age, experience and salary expected. Location Eastern Pennsylvania. 0126-D.

MECHANICAL DRAFTSMAN familiar with mill and machinery design for metallurgical and chemical plants. Advise experience, salary expected and references. Location Colorado. 0127-D.

SALES ENGINEERS for leading manufacturing concern. Men who can sell power-plant and engineering equipment, engines, pumps, air compressors, condensers, etc. An opportunity for men of character and ability. Must be draft-exempt or in Class 4. Give full details, age, education, experience, reference and salary. Location New York. 0128-D.

ENGINEERS to train and develop in the fundamentals of a firm primarily engaged in the distillation of coal tar with the resultant principal production of bituminous road and roofing materials; with the ultimate object of filling operating positions in various plants as foremen, head chemists, assistant superintendents or superintendents. Preferably men of chemical engineering training desired, but this is not essential. As contemplated work will eventually be of an executive nature; ability to handle men is a desirable asset. Location New York. 0129-D.

SEVERAL EXCEPTIONAL OPPORTUNITIES for permanent positions, both technical and operating, in a plant making a full line of non-ferrous metal products. Work now almost entirely on government orders. Location desirable. 0131-D.

DRAFTSMAN on structural and ornamental iron work. Prefer technical man experienced in shop detail. Permanent position. Location Kansas. 0132-D.

MECHANICAL ENGINEERS experienced in construction work or design for chemical plant. State experience in detail and salary expected. Location Philadelphia, Pa. 0134-D.

MACHINE-SHOP SUPERINTENDENT for small concern manufacturing interchangeable parts and automatic machinery. Technical graduate with five or six years' experience preferred. Must be above the draft age. Salary $2500-$3000. Location Illinois. 0135-D.

DRAFTSMAN familiar with boiler construction and design. Give age, experience and salary. Location Chicago. 0138-D.

MASTER MECHANIC experienced in handling machinists, pipe fitters, electricians, millwrights and tinsmiths, familiar with conveying machinery, pumps, lineshaft drives, etc. Prefer practical man who has worked in a mill. Salary commensurate with ability. Location New Jersey. 0139-D.

CONSTRUCTION ENGINEER, for work principally on power-plant machinery. Location Shanghai, China. 0140-D.

SALES ENGINEER familiar with heavy-duty crude-oil semi-Diesel marine engines. Position in the foreign office, Manila. 0141-D.

COMPETENT MAN on flue-gas analysis and power-plant fuel work. Generally good opening for the right man. Technical graduate preferred, but not absolutely required. Location Ohio. 0142-D.

SALES ENGINEER. High-grade, experienced, energetic salesman to take charge of district sales office and territory; only a hustling good salesman is desired. Technical education with experience in conveying machinery preferred, but not essential. Exceptionally fine opportunity offered. Please state full particulars of experience, age, previous employment, salary expected, etc. 0145-D.

ENGINEER thoroughly capable of selecting and installing machinery for the manufacture of steel files for a factory, and supervising manufacture after factory shall have been completed. Should be thoroughly familiar with the various processes of file manufacture. Location East. 0146-D.

OFFICE ASSISTANT. Man between 21 and 35 with knowledge of machinery, preferably with previous experience in tools and machines for sheet metals, to assist in general correspondence. State age and experience. Location Buffalo, N. Y. 0148-D.

GENERAL FOREMAN AND SHOP MAN for plant in New York State for superheaters. Man with foundry and general shop experience preferred. Apply by letter. 0153-D.

FOREMAN for small shop in New York City. Must be well informed on mechanics and able to standardize flash lamps and blow lamps. Business established over 50 years and has promise of a good future. Good opportunity for a technical graduate ambitious to prove his worth. Must be an all-round man. Salary to start $1200. Name confidential. 0157-D.

CHIEF DRAFTSMAN. Draftsman experienced in maps, broad and narrow-gage railroads, frame buildings, layout of equipment and the design of special machinery. Com-

pany will take care of U. S. Government orders entirely. It is a chance to do your bit. A man of ability will be given early recognition and a permanent position. Apply by letter, stating age, nationality, experience, references and salary desired. Location Pennsylvania. 0158-D.

SALES MANAGER for power-plant specialty business. Reply by letter. Location Pennsylvania. 0159-D.

ASSISTANT TO GENERAL MANAGER for large mill in New Hampshire. Man between 32 and 45 preferred who has had experience with the installation of scientific-management methods. Must be able to handle tactfully executives and employees. State salary, when available, and give references. 0160-D.

FACTORY SUPERINTENDENT. Prominent manufacturing corporation manufacturing light product of large variety—part stock, part special to order—requires aggressive, energetic factory superintendent thoroughly experienced in machine-shop practice and modern centralized planning control methods, capable of securing large production most efficiently and economically. To be considered, replies must fully state experience and qualifications. 0161-D.

ASSISTANT CHIEF ENGINEER. Graduate from technical college who is a good organizer and executive and capable of directing mechanical, civil and electrical forces of large manufacturing corporation. Must have considerable experience similar to above to qualify. Man 32 to 40 years old preferred. State full details of education, names of previous employers, positions held and salary desired. Location Cleveland, Ohio. 0162-D.

TECHNICAL GRADUATE for material department of firm handling all types of machinery. Purchasing and statistical experience desired. Salary to start $150 to $175, with excellent chance for advancement. Location New York. 0163-D.

SALES MANAGER. Engineer experienced in estimating and selling to hold responsible position in long-established engineering and contracting business of an incorporated company. Possible opportunity to become financially interested. Give age and experience in reply. 017-D.

SALES ENGINEER between 25 and 30 for condenser and cooling plants. State experience, salary expected, and give references. Location Philadelphia, Pa. 072-D.

SALES CORRESPONDENT. Engineering and correspondence experience such as involved in formulating proposals covering sale and calculation in steam and power-driven pumping equipment, including application of steam engines, and electrical equipment that may be employed. Applicant should supply references bearing upon a record as correspondent, closing of contracts, execution of orders and closing of accounts. Location New Jersey. 093-D.

DESIGNER for machine shop. Location Ohio. 0118-D.

ONE MECHANICAL AND ONE ELECTRICAL ENGINEER, preferably married men without children and willing to take positions at sulphur-refining factories at Marseilles and Cette, France. 2052-D.

RAPID DETAIL DRAFTSMEN AND DESIGNERS on electric furnaces, gas producers, heavy machinery for steel-plant and coke-oven equipment, coal- and ore-handling equipment and complicated structural details. Location Cleveland, Ohio. 2061-D.

TOOLMAKERS AND TOOL DESIGNERS experienced on jigs, fixtures and gages. Only first-class men need apply. Good wages and best of working conditions. 2155-D.

JUNIOR SALES ENGINEER, preferably engineering graduate with selling experience. Must be familiar with steam-specialty apparatus. Location New York. 2158-D.

DESIGNER of power-plant work. College graduate preferred. Salary $125-$180 according to man. Location New York. 2162-D.

CHIEF DRAFTSMAN to take charge of a dozen men and experienced in design of tools, jigs, and fixtures. Prefer a man from 25 to 35 years with shop experience in the manufacture of interchangeable parts and with executive ability so that he can assist the superintendent directing the technical work. Salary $200 to $250 per month to start. 2200-D.

COLLEGE GRADUATES, ENGINEERS. Men out at least a year for general shop-engineering work with growing concern. Work leads to industrial management. State full particulars. Location New Jersey. 2478-D.

MASTER MECHANIC for large central power plant. Permanent position with chance for advancement. State age, experience, salary expected and position regarding draft. 04-D.

HEATING AND VENTILATING ENGINEER to supervise design, installation and work in advisory capacity in connection with maintenance in large rubber factory in northern Ohio. Salary commensurate with training, experience, and ability to handle men. Splendid opportunity for the right man. 2561-D.

APPRAISAL ENGINEER experienced in appraisals of industrial properties. Technical man preferred. Location at start in New York and later to have charge of branch office in large Middle West city. State experience, age and salary expected. 0164-D.

INVENTORY AND APPRAISAL DEPARTMENT ENGINEER for one of the Eastern State commissions; man with technical training as mechanical engineer, and with one year or more of experience in engineering work preferred. Some knowledge of accounting and of appraisal work desirable but not essential. Present engineering staff is small; good opportunity for advancement for the right man. Location Newark. 0168-D.

INSTRUCTOR in elementary mathematics and mechanical drawing for Apprenticeship School. Candidates should have had some technical training and shop experience and should understand the handling of young men. Position offers excellent opportunities for advancement in the works and will pay an initial salary of $1200 or more per year, according to the caliber of the man. Location Connecticut. 0176-D.

MEN AVAILABLE

ASSISTANT to the president or general manager of a manufacturing corporation is a connection desired by a competent industrial engineer, age 32. Graduate engineer and accountant, engaged two years in construction and design and seven years as consultant in industrial operation. Experienced in wide range of industries, including textile, machinery, foundry and steel. Wishes now to obtain settled address. Offers convincing references. D-85.

TECHNICAL GRADUATE, associate-member, age 33, with over 10 years' experience in planning, design, erection and operation of power-plant and manufacturing equipment, desires new connection as mechanical engineer or in other executive capacity for which his ability and experience would qualify him. Complete record with best of references on request. Location preferred Pacific Coast States. D-86.

PRODUCTION MANAGER experienced on aeronautical engines and parts and high production on light-weight machinery desires position as executive on Government work. Expert tool designer; experience in shop efficiency and cost recording; understands all classes of automatic machine work, including sheet-metal stamping. Salary about $300 a month. D-87.

MECHANICAL ENGINEER AND EXECUTIVE, age 30, at present in charge of engineering department of large manufacturing concern. Good on automatic-machinery, jig, die and tool design, for interchangeable manufacture. Practical shop man who can supervise work from drawing room to completion, and is an expert on factory layouts and equipment. Salary $2500 to $3000. D-88.

EXECUTIVE SALES ENGINEER now holding responsible position for five years as sales manager desires similar position with company having larger field. Has traveled extensively and is well acquainted with automobile and machine manufacture. Graduate mechanical engineer, good executive, and of pleasing personality; alert and resourceful, and exercises well-balanced judgment in all propositions. D-89.

MECHANICAL ENGINEER, age 44, with 12 years' manufacturing experience, desires a change. Expert in the design of special machinery for economical production, making investigations and experiments, and following work through to completion. Resourceful, tactful, and successful as an executive. Minimum salary $3000. D-90.

MECHANICAL ENGINEER, age 34, desires to locate in Brooklyn or near New York City. Twelve years' experience in industrial plants, covering design, maintenance and construction work. Salary commensurate with ability. Only permanent position will be considered. D-91.

GENERAL MANAGER OR PRODUCTION SUPERINTENDENT. Member, American, age 46, with 23 years' technical training, practical shop experience and shop management manufacturing steam and gas engines, electric motors and generators, mining and transmission machinery, dairying machinery, pumps, shrapnel and high-explosive shells, time and graze fuses. Shop training covers production from design through shops to assembly, test and shipping. Technical covers building and plant extension, hydraulic-pneumatic, electric and steam power plants, machine-tool design. Office experience covers routing, costs, time study, wage systems, estimating and purchasing. Organization, systematizing, correct arrangement of machinery, proper routing of material, rapid, accurate production with unskilled labor by means of foolproof jigs and tools with coordination of departments has always shown increased output and reduction of costs. D-92.

MECHANICAL ENGINEER with 15 years' experience in the design of power plants, industrial plants, heating, ventilating, etc. Has had charge of men and shown executive ability. At present holds responsible position but has very little work to do. Willing to consider responsible and permanent position only. D-93.

YOUNG MECHANICAL ENGINEER. Technical man with 5 years' practical experience as designer and engineer desires change. Experienced on tools and equipment for manufacturing both large and small interchangeable parts. D-94.

PUBLICITY ENGINEER. Technical graduate who is over draft age and thoroughly experienced in advertising and cataloguing mechanical appliances desires permanent position with high-class manufacturing concern. American, good health and appearance clean record. D-95.

SUPERINTENDENT machanically trained and educated, thoroughly conversant with today's methods of production, and experienced in laying out the proper lines to follow in economical and interchangeable manufacture. Twenty years' successful practical experience in the manufacture of fine tools, reamers, dies, etc., light automatic machinery, hand screw machines, and cylindrical grinding machinery. Capable of taking entire charge of entire factory, but willing to accept position as assistant to high executive in large plant. Now employed as general superintendent. D-96.

MECHANICAL ENGINEER who has specialized on drop forgings desires to make a change—reasons on request. Age 32, married, American-born of American parents. Desires permanent position with reliable concern. Salary $2500 to $3000. D-97.

MECHANICAL ENGINEER. Technical graduate, age 25, married, desires position April 1. Has had one year of factory and shop experience and three years' intensive experience in the practical operation, maintenance and erection of Diesel oil engines, producer-gas engines and high-duty steam pumping engines. D-98.

FACTORY EXECUTIVE. Member, American, age 40, married. Technical college training and 18 years' successful experience with largest manufacturing concerns as chief draftsman, superintendent and manager in developing, organizing and producing. Six years in present position. Best of references. Responsibility of full authority. Salary $6000. D-99.

WORKS MANAGER OR GENERAL SUPERINTENDENT. Broad-gage, fully trained executive, age 36, desires connection with large plant making any product from automobiles to clocks. Experienced in plant layout, best shop practice, management control methods, systems and man training: successful in all jobs through production, design and control divisions. Man whose vision is equal to possibilities of business and accustomed to make plans become facts. D-100.

GENERAL MANAGER OR GENERAL SUPERINTENDENT wants position on either Atlantic or Pacific Coast. Thoroughly versed in design and construction of marine engines and boilers and stationary engines. Varied practical and theoretical training and experience. Accustomed to responsible positions. Satisfactory reasons for desiring change from present position. D-101.

TURBINE DRAFTSMAN. Junior member, age 27, married, desires position with small, growing concern in engineering or sales department. College graduate with 6 years' turbine experience. At present employed as assistant to chief draftsman. Salary to start $150. D-102.

SKILLED OPERATING ENGINEER, experienced in design, construction, and operation of modern power plants, will consider a position to take full charge of a plant of 5000 kw. or larger. Can show results in the boiler room and get the best results from the equipment. At present mechanical engineer for a group of properties. D-103.

JUNIOR MEMBER, age 29, married, desires position as assistant professor of drawing and mechanical engineering. M. E. degree from a prominent eastern university. Some executive experience serving as director of department for one year. Location eastern college or university preferred. D-104.

ASSISTANT SUPERINTENDENT OR ASSISTANT ENGINEER. Associate member, age 35, with three years' experience as assistant engineer and engineer of tests on Diesel oil engines. Over six years mechanical engineer for large textile concern in charge of all mechanics, buildings, machinery and building construction and yard improvements. D-105.

EXECUTIVE OR ASSISTANT TO SUPERINTENDENT OR MANAGER. Member, American, age 50, married; practical mechanic, draftsman and designer. Thirty years' manufacturing experience, covering pattern, forge, iron and brass foundry, and machine shops; also 5 years' erecting experience throughout New England. Can handle correspondence, make estimates, figure costs, etc. Especially familiar with hydraulic work, comprising pump, tank and pipe problems. Well versed in plant upkeep, purchasing, etc. Location desired eastern New England. Salary $2500. D-106.

INDUSTRIAL AND PRODUCTION ENGINEER. M. E., age 31, married, with 12 years' active shop, field and office experience in the design, manufacture and production of industrial machinery and plants. Good organizer and tactful executive to introduce, develop or maintain bonus, cost and stock systems, standardization, scheduling, routing, and other production problems, to meet actual conditions. Good reasons for leaving present connection of five years, with large corporation in above capacity. Salary $3600. D-107.

SUPERINTENDENT, PRODUCTION MANAGER, EFFICIENCY ENGINEER, MASTER MECHANIC. High-grade executive with 22 years' practical and technical experience in manufacturing, covering every branch of the metal and wood manufacturing line, including the business end. Expert on equipment and system. Have had charge of plants employing up to 6000 men. At present employed as consulting and efficiency engineer. Thoroughly versed in gray-iron and brass foundry practice. Desires permanent position where efforts will be recognized. D-108.

MECHANICAL ENGINEER. Member, technical graduate, American, desires position as assistant engineer or chief draftsman. At present employed as designer, estimator and testing engineer. Sixteen years' experience, including testing, designing excavating machinery, tractors, derricks, hoisting engines, cargo winches, steering engines, anchor windlasses, and miscellaneous machinery, office engineering, machine-shop and steel-foundry practice. Location Middle or Far West preferred. D-109.

MECHANICAL ENGINEER. Junior member. Cornell graduate, M.E., age 27, American, married, classified in 4th class of Federal draft. At college, specialized in design of internal-combustion engines; since then employed as draftsman and assistant office executive, in which position duties consisted of testing steam power plants, adjusting complaints on coal, and handling correspondence. At present employed in the latter capacity. Minimum salary $2100 per year. Location preferred, New York. D-110.

EQUIPMENT ENGINEER. Graduate of English college of recognized standing, age 27, married. Experienced in the manufacture and inspection of interchangeable parts and design of equipment. Can take charge of drawing room and would like to get in touch with a firm concerning a permanent position. At present employed. D-111.

MECHANICAL-ELECTRICAL ENGINEER. Michigan graduate, age 32. Four years' experience in consulting engineering, designing, testing, estimating and writing reports on power plants and power equipment and four years' experience in selling electric and steam power service for central station. Available in two weeks. Salary $2500-$3000, depending on location. D-112.

EXECUTIVE MECHANICAL ENGINEER. Member, age 41, American, married. Twenty years' practical experience as designer, chief engineer, general manager, and consulting engineer. Thoroughly conversant with all details of shipbuilding—medium-sized steel and wooden steamers, machine and foundry business, manufacturing special machinery and tools, steam engines, boilers, hoisting machinery, dredging and excavating machinery, marine auxiliaries, and repairs to same. Desires change, preferably with new company on war contracts, ships, engines or special machinery. Permanent executive position considered, or temporary war business on a consulting basis. D-113.

MECHANICAL ENGINEER. Member, age 44, with 17 years' experience with steam railroads and 3½ years on valuation work, desires to make change. Technical graduate, now employed. Salary $4800 or better. D-114.

DESIGNING ENGINEER. Graduate mechanical engineer, 37 years old, with 14 years' varied engineering experience, principally on the design of power machinery and machinery location plans. At present employed but desires a permanent position. Replies desired only from those actually in need of a man for permanent position. D-115.

ASSISTANT GENERAL SUPERINTENDENT OR WORKS MANAGER, OR GENERAL MANAGER OR ENGINEER OF SMALL PLANT. Young mechanical engineer who has successfully held similar responsible positions and served adequate time in shop and drawing office. Specialized on production work, having full charge of designing and building internal-combustion engines and automatic machinery. Capable executive, thoroughly practical and aggressive, at present employed as chief draftsman of a large concern. 33 years of age, married. 18 years' total experience. D-116.

EXECUTIVE OR MANAGING ENGINEER. Member, age 43, married, 20 years' engineering experience. Good organizer and executive, experienced in design of locomotive engines, cars and heavy machinery, as well as in the direction of shop, drafting-room and office forces. Familiar with estimating and sales engineering. Highest-class references. Salary $5000 or equivalent on bonus or commission plan. Eastern location preferred. D-117.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

Research Information Committee Formed

The following statement is authorized by the Council of National Defense:

1 By joint action the Secretaries of War and Navy, with the approval of the Council of National Defense, have authorized and approved the organization, through the National Research Council, of a Research Information Committee in Washington with branch committees in Paris and London, which are intended to work in close coöperation with the officers of the Military and Naval Intelligence, and whose function shall be the securing, classifying, and disseminating of scientific, technical and industrial research information especially relating to war problems, and the interchange of such information between the allies in Europe and the United States.

2 The Washington committee consists of—

a A civilian member, representing the National Research Council; Dr. S. W. Stratton, Mem.Am.Soc.M.E., Chairman.

b The Chief Military Intelligence Section.

c The Director of Naval Intelligence.

3 The initial organization of the committee in London is—

a The scientific attachè representing the Research Information Committee: Dr. H. A. Bumstead, attache.

b The military attaché, or an officer deputed to act for him.

c The naval attaché, or an officer deputed to act for him.

4 The initial organization of the committee in Paris is—

a The scientific attaché representing the Research Information Committee: Dr. W. F. Durand, Mem.Am.Soc.M.E., attaché.

b The military attaché, or an officer deputed to act for him.

c The naval attaché, or an officer deputed to act for him.

The headquarters of the Research Information Committee in Washington is in the offices of the National Research Council, 1023 Sixteenth Street; the branch committees are located at the American Embassies in London and Paris. (*Official Bulletin*, March 8, 1918, p. 8.)

New U. S. Bullets Deadly to Planes

Special bullets, designed for aerial work, that combine armor-piercing and incendiary qualities, and also armor-piercing and tracing, have been developed by the War Department to a point fully equal to or surpassing those used abroad.

Armored-airplane construction, adopted since the European war started, brought the necessity for a new type of bullets. The necessary type was developed for use against the gasoline tank of enemy machines, the most vulnerable spot, and the tracer bullets enable the aviator to judge the result of his fire just as well at night as in daylight. The size of the bullet has been kept to 0.30 caliber, and types have been perfected that gave splendid results in tests.

"With the progress of the war," says the War Department statement, "the more vital parts of the airplane were protected with light armor, so that it became necessary to introduce the armor-piercing bullet.

"As the gasoline tanks were particularly susceptible to explosion, it was necessary to procure a bullet containing an inflammable substance ignited upon discharge, which would carry the spark of flame into the tank when piercing it.

"As the target was within range for only brief moments at a time and as there was no means of determining the fire effect, as on land, a tracer bullet containing a bright-burning composition was introduced. The composition is set on fire upon discharge and the bullet flies through the air as a bright spark, plainly visible to the machine-gun operator.

"At the outbreak of the war further information was promptly gathered from the Allies and this subject was studied by those responsible for this work in the United States. Of course, on account of the difficulties of the problem, none of the special bullets possessed by any country is entirely satisfactory, or what might be termed 'perfect' in operation.

"The bullets developed by the United States Ordnance Department have been tested on land and from airplanes to see if there is any difference in their performance when fired from a quickly-moving airplane in the upper atmosphere and when fired on land. These tests indicate that the United States has developed a class of special cartridges with a performance fully equal to or surpassing that attained abroad." (*Philadelphia Public Ledger*, March 4, 1918, p. 6.)

The Liberty Motor

Several official statements have been made to the effect that the Liberty motor is in production. In fact, it has been stated that the various companies now engaged in its production, such as the Packard Company, the Lincoln Motors Company, etc., have or soon will reach a daily production of 250 engines a day.

The aeroplanes shipped to France have been equipped with the Liberty motor. Likewise, in the early part of March, the first fighting seaplanes built in America have been accepted for service. These seaplanes, which are said to be substantially similar in construction to the British flying boats, are each equipped with two Liberty motors giving a useful output of about 700 hp.

In the final tests and refinements of the motor the Aircraft Board was assisted by a supervising committee consisting of D. McCall White, Mem.Am.Soc.M.E., and Henry M. Crane, Mem.Am.Soc.M.E.

A bit of light has been thrown on the history of the Liberty motor by Emden S. Hare, president of the Packard Motor Company of New York, in an address at the dinner of the Sphinx Club in New York. According to this statement the Liberty motor was the outcome of three years' work on the part of the Packard engineers. The company offered this engine to the Government. At the time, the Aircraft Board felt that it would be best in the furtherance of their war plans not to put this motor out under the name of the Packard Company, and the company patriotically sacrificed its private interests in the motor and consented to let its work be merged under the name of Liberty motor.

Conjoint Board of British Scientific Societies

A report on the work of the Board for the first year of its existence, 1916-1917, has been issued.

On March 22, 1916, at the instance of the Council of the Royal Society, a conference was held with representatives of the leading scientific societies at which it was decided to organize such a conjoint board.

The Board was eventually organized for the purpose of promoting the coöperation of those interested in pure and applied science; supplying a means by which the scientific opinion of the country may, on matters relating to science, industry and education, find effective expression; taking such action as may be necessary to promote the application of science to industries and to the service of the nation; in discussing scientific questions in which international coöperation seems advisable.

The Board consists both of purely scientific societies, of engineering organizations, such as the Institutions of Civil, Electrical, Mechanical, and Mining Engineers, semi-engineering organizations like the Geological Society, and organizations of the type of the Physical and Zoological Societies. Even the Biochemical Society and the Psychological Society have found a place in the wide scheme of organization of the Conjoint Board, which thus represents the scientific and engineering mind of the country in the broadest and best sense of this term.

As regards financing, the Royal Society extended to the Conjoint Board the hospitality of its rooms and guaranteed the expenses of the Board to the sum of £200 during the first year. In addition to this, the constituent societies each contributed sums varying from £10 to £50. A number of important sub-committees were appointed and a majority have presented final or interim reports.

Thus the Sub-Committee on the Application of Science to Agriculture has, among other things, initiated a careful census in districts where there are various classes of agriculture, the object of the census being to ascertain the amount of produce sent out from, and the raw materials conveyed to, these districts; the time when such transport is effected, as well as the time occupied in seasonal operations on the lands. It is hoped from this detailed information to obtain valuable data on which to build practical estimates of the power required and cost of operation and compare the relative advantages and costs of steam engines, internal-combustion engines and electrically operated machinery.

The question of application of electrical machinery to agriculture has received particular consideration, the Sub-Committee emphatically believing in its great future. In fact, the Sub-Committee believes that electrical power can be distributed to farms at prices which would pay the farmer. Electrically propelled plows and other agricultural machinery would be simpler in construction and easier to handle and inspect than oil-driven machinery. Further, electricity may be used for intensive cultivation, as is indicated by some recent experiments.

Another sub-committee is instrumental in drawing attention to the need of national instruction in technical optics.

A Watching Sub-Committee on Education has been instituted in order to keep the Board of Scientific Societies informed on any matters in education which might arise from time to time and might have a bearing on the relation of education in science to national needs and to the special requirements of scientific industries. Its chief attention has been occupied so far with an attempt to secure unity of purpose between those anxious to insure that natural science shall, in the future, form a more important part in early education than has been the case in the past and those who have had their interests more particularly concerned with the development of literary and linguistic studies.

A Metric Sub-Committee was organized in 1917 and is now engaged in the preparation of a report. Other sub-committees are apparently vigorously at work.

Boston Society of Civil Engineers

FOUNDATIONS OF THE NEW BUILDINGS OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY, CAMBRIDGE, MASS. A paper with this title was presented at the December meeting by Charles T. Main, President, Am.Soc.M.E., and H. E. Sawtell. The purpose of the paper was to describe the geological conditions found at the site of the Massachusetts Institute of Technology and the methods used in determining these conditions, the selection of the type of foundations and the pile tests, load tests and designs of portions of the foundations. Because of lack of space only the latter part of this interesting paper can be reported here.

Two considerations led to the selection of wood piling in preference to concrete piles. First, it was found that wood piling would be considerably less expensive than concrete piles, because of the fact that the permanent water level was high and hence it was unnecessary to place any concrete in addition to that required for the foundations to meet the heads of the wood piling. Further, large piles do not prove economical where flexibility is required for light as well as heavy loads. In this case it was decided that heavy concentrated loads should be avoided, which in itself precluded the use of concrete piles.

In order to determine the kind and length of wood piles to use in different parts of the site, a sufficient number of tests became necessary, a rather difficult task owing to the great variety of soil conditions present.

The complete data of these tests, especially valuable because of the wide ground covered, are given in a series of tables. Some of the piles (spruce) were driven into the "glacial gravel," in this instance a well-compacted and deep bed of material, commonly known as coarse sand and gravel, to various depths, and upon being pulled were all found to be broomed or both broomed and broken.

This showed that spruce piles could not be driven with safety into the harder portions of the glacial deposit, and the use of spruce was confined to those places where friction was largely depended upon to give the bearing value and very little dependence placed on point bearing. Also it was decided not to use spruce piles when sudden changes in the hardness of the soil were found or expected.

On the other hand, tests proved that first-class oak piles could be driven without injury into well-compacted coarse sand or fine to a resistance giving a value of 18 tons or more. Hence, oak piles were used when the driving was hard and when the supporting value of the piles was to be gained largely from point bearing and relatively small embedments in the hard stratum.

The varying conditions of the ground made it necessary to take particular care to design the pile foundations on the basis of as nearly uniform settlements as possible. Such

uniformity is highly desirable in order to prevent overstressing the more or less continuous concrete floor of beams and slabs used in the superstructure of the buildings.

It was considered necessary that the piling have a safety factor of not less than 2.5 of tonnage, based on the limit of ¼-in. settlement.

An effort was made to keep the piles in the glacial deposit, even where it thinned up, as it was desirable to use this stratum as a medium for spreading the loads over the clay under it.

It was endeavored to have a minimum of at least 3 ft. of gravel under the points, even where it became thin, in order to make the spreading of the load somewhat effective.

Regarding the safe working values, the tests have shown that the piles driven into sand and dependent upon friction for support could be used at their formula valne (the so-called *Engineering News* formula is referred to), but not much higher than the limits of settlements and safety factors assumed. On the other hand, piles embedded in the clay found at this site showed an ability to carry test loads in excess of the formula value when using drop hammers.

A feature in the design of these foundations which was given some consideration was the matter of vibration due to external and internal forces. It was expected that the greatest vibration would come to the structure from external sources, such as freight trains, electric cars, etc., conveyed to the buildings by means of the comparatively hard top film which lies over the stratum of mud, silt and peat.

As a matter of fact, nearly the entire site of the new buildings has a stratum of mud, silt and fill above the glacial deposit and clay. The buildings have a foundation of piles, which have their entire length above the part embedded in sand and gravel or clay, pass through a material affording very little support, and it is known that structures supported in this way not only readily send out vibrations but are strongly affected by vibrations from other sources, if situated above the same strata.

One method of partially resisting such a tendency is to drive the piles well into the supporting stratum rather than resting them on the surface or with a foot or two of penetration, but as a fair embedment was necessary anyway to get the bearing values desired, the question of stiffness was solved automatically.

Working rules for governing the driving of piles are given. (*Journal of the Boston Society of Civil Engineers*, vol. 5, no. 1, January 19, 1918, pp. 1-38, 16 figs., *de.*)

U. S. BUREAU OF STANDARDS

Central Hot-Water Heating. The Bureau has made studies of central water-heating systems in fifteen cities in the Middle West, for the purpose of formulating technical standards of service for such central heating systems. The work is carried on in close coöperation with the engineers of the Indiana Public Service Commission and with the Educational Committee of the National District Heating Association. The results will be embodied in a circular entitled Standards of Service for Central Heating Plants, similar to the circulars already published by the Bureau of Standards on Standards of Gas Service and Standards for Electric Service.

Gas Engineering. The readjustment of gas quality and rates is an acute question in several states. This situation enabled the Bureau to render prompt service by the application of the experimental results obtained by the Bureau last year. The appointments of a number of additional gas engineers are now pending. These will enable the Bureau to take up pressing problems in gas engineering.

Military Research. Confidential investigations are in progress on gun-firing measurements, sound ranging, battleship telephony, lighting, optical instruments, signaling, aeroplane construction, thrust and torque, use of concrete for ships, and many other similar subjects of importance in the war. The nature of these problems is, of course, confidential, so that the results will not be known until the close of the war or until published by the Military Departments. A new laboratory, somewhat larger than any of the existing bureau laboratories, is to be constructed in the immediate future.

Electrolysis Survey. The Bureau of Standards is preparing the report on a survey of the city of New Orleans, in which the electrolysis conditions were very carefully investigated. The request for this survey was made jointly by the city of New Orleans and the utilities companies concerned. The report will give the recommendations to the city and to the utilities for ameliorating the unfavorable conditions found.

Inspecting and Testing of Electric Lamps. The Bureau's work during the past six months has been nearly three times the amount for the previous year. The great demand has led some factories to deliver lamps of lower quality than heretofore, but this has been corrected in the recent deliveries.

Infra-Red Spectroscopy. Hundreds of new lines have been discovered by the Bureau in the infra-red spectroscopy of iron, cobalt and nickel. The investigations have been completed as far as the apparatus and photographic methods permit. Many of the newly discovered lines of wave lengths are greater than 10,000 angstrom units. The reports have been prepared for publication.

Weathering of Optical Glass. The effects of the collection of water vapor and resistance to the weathering action by different types of optical glass are being investigated by the Bureau. It is expected that these investigations will develop means of producing a better quality of optical glass. Large numbers of optical parts and optical apparatus are being tested for the military departments and special problems are under investigation, especially those which have arisen from the use of American-made optical glasses.

Engineering Instruments. Typical examples of calibration work in this division included during the past month water-current meters, pressure and vacuum gages, relief valves, and a fatigue test of a pressure gage in an investigation using 30,000 lb. per sq. in.; pressure tests of metallic tubing and copper spheres, fire extinguishers, and similar lines of engineering tests.

Tensiometer. The Bureau has devised an instrument and constructed it for the purpose of measuring the loads on cables. The test was successfully completed and the instrument calibrated. Large numbers of woods, metals and structural parts have been tested on the large Emory testing machine for military purposes.

Building-Stone Investigation. The automatic freezing and thawing apparatus which has been in continuous operation during the past month has subjected to alternating freezing and thawing a number of sandstones and limestones, as high as seven hundred and fifty alternations in some cases. Most of the samples showed visible signs of disintegration. The aim is to ascertain the effect of frost action on building stones,

concrete, etc., and establish the relative durability of the various types. The specimens are shifted automatically between a cold chamber and a warm chamber at suitable intervals to permit freezing and thawing. In this manner the freezing equivalent to years of exposure may be obtained in a comparatively short time.

Effect of Calcium Chloride on the Strength of Concrete. This investigation was undertaken to determine the effect of using solutions containing small amounts of calcium chloride as the gaging water in mixing concrete on the rate of increase in strength of concrete. Results to date, including tests of concrete a year old, show that an aqueous solution of from 4 to 6 per cent of calcium chloride used as the gaging water of portland-cement concrete will increase the strength at two or three days from 50 to 100 per cent over concrete of the same proportions and age gaged with plain water. No detrimental effect has as yet been noted on the concrete in which the calcium chloride has been incorporated.

Tests of Leather. An investigation of the wearing qualities of the different grades of leather in actual service and as tested by the Bureau of Standards leather-testing machine is now being carried out on a much larger scale than before. The District of Columbia postmen have been furnished with shoes with sole-leather and fiber-composition soles. One is placed on one foot, the other on the other. The test is being extended to include soldiers at Camp Meade. A careful record is kept of their behavior, the nature of wear, weather conditions, etc. A representative of the Leather Section of the Bureau makes weekly inspection trips to Camp Meade.

Optical Glass. The Bureau's work on optical glass is progressing satisfactorily. During the month sixteen melts were made, ten in pots manufactured at the Bureau and two in porcelain pots. The glasses made included a dense flint of fine color, the usual medium flints, light crown, boro-silicate and light barium crown glasses. The tests of porcelain and semi-porcelain glass pots are being continued. The large porcelain pots have proven to be very successful.

Tile Investigation. Nine full-size hollow-tile walls were tested in the 10,000,000 lb. compression machine. The walls varied from 6 to 12 in. in thickness, were each 4 ft. wide and 12 ft. high, and were laid in cement mortar tempered with lime hydrate. The walls were laid up with the flues horizontal instead of vertical, which distinguishes this series from the previous one. These walls showed only about 36 to 50 per cent of the strengths when tested vertically and with the vertical flue walls carrying from 300,000 to 600,000 lb. load. The tendency to local fracture in the outer webs of the tile is the rule when the flues are laid horizontal, although there is a better bonding. A great deal of interest has been shown by building code experts and tile manufacturers in the tests. About thirty walls have been tested thus far and the tests are being continued with the coöperation of manufacturers.

This Month's Abstracts

In the next issue of The Journal will appear one or more abstracts from *La Technique Moderne*. This important French publication was discontinued soon after the beginning of the war, but is starting again. This is a welcome sign, showing that not only is the technical life of France getting back on its feet, but also that the general situation in the country cannot be very bad if an expensive technical journal finds enough subscribers to keep it going.

In the section Aeronautics, Lieut.-Col. Crocco of the Italian Arm presents an interesting discussion on the resistance of air when the matter is considered not as a perfect fluid, but, on the contrary, as a dissipater of energy. Certain aerodynamic phenomena are then considered from the point of view of valuation of momentum communicated to the air, which was originally immobile.

In the section Engineering Materials are reported the cardinal features of an investigation on the strength of sewer pipe.

In the same section will be found a discussion of the properties of wire rope for aircraft of particular interest in that it brings out how the method of manufacture, especially the speed in stranding and closing the rope, affects its ultimate physical properties.

A paper read before the Kentucky Ice Manufacturers' Association by W. D. Stuckenberg and J. F. Kohout presents some interesting features in connection with storage and weathering of coal. A point of particular interest brought out is the influence of outside sources of heat on the spontaneous ignitability of coal, including the influence of sun heat.

In the section Fuel is also described a new method of burning powdered coal, the distinctive feature of which is that the arrangement is such that the powdered fuel, thoroughly dried, is conveyed practically as if it were a fluid. This permits the use of a comparatively small size of piping of long length and at any necessary tilt or angle. An interesting system of regulation of the supply of coal is provided.

From the *Journal of the Society of Chemical Industry* is taken a brief report of an investigation on the melting points of coal ash. In the original paper a table is given of melting points of a number of ashes.

In *Power*, Sanford A. Moss, Mem.Am.Soc.M.E., describes a method of measuring high pressures of gases with dead weight as used at the Lynn Works of the General Electric Company. The dead-weight pressure gage is said to be more precise than the Bourdon gage, while quite simple in operation and calibration.

The description of a new hydrometer is indirectly taken from a German paper.

In the section Mechanics a lecture by Sir James Dewar before the Royal Institution is abstracted, giving interesting details of his recent studies of liquid films.

In a paper before the Society of Automotive Engineers, Arthur B. Modine discusses the principles of tractor-engine cooling, and, among other things, emphasizes the fact that the rate of cooling effected in the radiator is a function not only of the rate of flow of the air through the radiator, but also of the rate of flow of water.

An extensive discussion of electric boiler heating for steam locomotives is abstracted from a German publication.

Through the *Railway Age* is abstracted an extensive report on the study of railway track under load carried out by a special joint committee of the American Society of Civil Engineers and the American Railway Engineering Association.

In the section Steam Engineering, particular attention is called to two abstracts; the first describing the 50,000-kva. Connors Creek turbines of the Detroit Edison Company, and the second discussing steam raising by electricity with heat storage, this latter being the data of an experimental investigation carried out in 1916 in Switzerland.

Several interesting abstracts appear in the section Thermodynamics, notably one of an article by H. P. Gillette, Mem.Am.Soc.M.E., in which the writer examines the gas-film theory in its relation to heat conduction.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Tools, Munitions, Varia

Aeronautics

Approximating the Static Thrust and Brake Horse Power of Air Propellers, W. Bernard Murphy. The static thrust and b.hp. of air propellers are here discussed on the basis of the formulæ for air screws developed by W. R. Turnbull and published by him in the *Aeronautical Journal* for January 1912. The article is illustrated by two charts, one giving the values of the coefficient Q in the Turnbull formula and the other the coefficient of U for flat-face sector screws. The first chart is for a two-blade and the second chart for a two- and four-blade propeller. (*Aviation and Aeronautical Engineering,* vol. 4, no. 2, February 15, 1918, pp. 89-90.)

The Influences of Standardization in War Aeronautics. The influences of standardization are discussed from two points of view: the one as they affect production and the other as they affect the developments of types. Standardization is defended as a means of increasing the speed production and attacked as possibly retarding the development of the best types. (*Journal of the Aeronautical Society of America*, vol. 2, nos. 20-24, July-December 1917, pp. 3-24.)

The Two Cardinal Principles of Aerodynamics, Lieut.-Colonel Crocco. The article discusses the resistance of the air from the point of view of considering the air not as a perfect fluid, but, on the contrary, as a dissipater of energy. Theoretical results of considerable importance are obtained in this way, even though the practical dependence of propelling power on the way in which the disturbed air circulates and loses its energy is limited to the cases in which the size of the closed spaces where the experiment is made is out of proportion to the sizes of the generated fluid jets. The writer introduces in aerodynamic phenomena a principle for the valuation of generative forces, which is that of momentum communicated to the air which was originally immobile. (*Aeronautics*, vol. 14, no. 224 (new series), January 30, 1918, pp. 104-110, 10 figs.)

Mechanics of Aeroplanes at High Altitudes. Herbert Chatley. *Aeronautics,* vol. 14, no. 224 (new series), January 30, 1918, pp. 114-116.

Dope Poisoning. *Automotive Industries,* vol. 38, no. 10, March 7, 1918, pp. 493-495.

On the Statics of Screws, Rodolphe Verduzio. *Aeronautics,* vol. 14, no. 225 (new series), February 6, 1918, pp. 128-129.

Air Engineering

Blast-Furnace Preheater. Description of new blast-furnace preheater invented by E. E. Marshall. The principle of this device is to take air coming from the blast engines and pass it through a preheating device prior to its admission into standard firebrick stoves. It is claimed that in this way a more even temperature is secured.

The construction of the preheater is the same as that of the old iron-pipe stoves used in blast-furnace practice prior to the invention of the modern firebrick stove. It consists of a combustion chamber, a pipe chamber and a draft-stack chamber. The gas and blast flow in parallel. This is done to keep the first row of pipes cool by the incoming blast, and thus protect them from warping and burning out. The blast is heated under predetermined temperature in the preheater up to 900 deg. fahr. The action of the preheater on the stoves is as follows:

The firebrick stoves coming off of gas are put on the furnace. The preheated blast is admitted through the cold-blast valve on the stoves. As the preheated blast has attained a rather high degree of heat in the preheater, the heat surface of the stoves is not cooled off as fast as it could be if cold blasts direct from the blast engines were admitted to the same heat surface. Hence the reduction in stove temperature during the period that the stoves are on the furnace is not large, and the blast gets a more uniform degree of heat. It is claimed that because of this small variation in the blast temperature the amount of fuel is reduced. It is also stated that with the preheater connection on the stoves, the checkers in the stoves do not accumulate dirt as they do without this adjustment.

It is stated that such preheaters have been installed at Newport, Pa., and at the Lochiel furnace at Harrisburg, Pa., with satisfactory results. (*Iron Trade Review*, vol. 62, no. 9, February 28, 1918, pp. 541-542, 1 fig., *d*)

First Report to the Council of the North-East Coast Institution of Engineers and Shipbuilders on Certain Methods of Producing High Vacuum, Edwin L. Orde, C. W. Cairns and J. Morrow. *Transactions of the North-East Coast Institution of Engineers and Shipbuilders*, vol. 34, pt. 2 February 1918, pp. 83-132, illustrated.

Ventilateurs Sulzer. *Bulletin Technique de la Suisse Romande,* 44 annee, no. 2, January 26, 1918, and no. 3, February 9, 1918. Description of Sulzer blowers made in Switzerland (to be continued).

Blast Furnaces (See Air Engineering)

Engineering Materials

THE STRENGTH OF SEWER PIPE. An abstract of Bulletin No. 47 of the Engineering Experiment Station of the Iowa State College of Agriculture on the supporting strength of sewer pipe in ditches and methods of testing sewer pipe in laboratories to determine their ordinary supporting strength.

It has been proved that the pipe in the ditch is so much more rigid than the ditch filling at each side of the pipe, that even with careful tamping the pipe carries practically all of the vertical load at the level of the top of the pipe caused by or transmitted through the ditch filling.

The width of the ditch at the elevation of the end of the top 90-deg. quadrant is the width factor that affects the load on the pipe. The ditch may widen indefinitely above this level without increasing the load on the pipe appreciably.

The following formula has been deduced for the loads on pipes in ditches where the trench is hollowed to conform to the bottom quadrant of the circumference of the pipe:

$$W = Cwb^2$$

where W = load on pipe in ditch, lb. per lin. ft.
C = coefficient (see Table I in original article).
w = weight of ditch-filling material, lb. per cu. ft.
b = breadth of ditch a little below the top of pipe, ft.

In computing the ordinary supporting strength of pipe per unit of length, the net inside length of the pipe from the bottom of the hub socket to the extremity of the spigot end should be used as a divisor. For calculating the modulus of rupture of sewer pipe from the ordinary supporting length, the formulæ already adopted for drain tile by the American Society for Testing Materials should be used, as follows:

$$M = 0.20rW/12, \text{ and } F = 6M/t^2$$

where M = maximum bending moment in the pipe wall of the barrel of the pipe, lb-in. per inch of length.
r = radius of the middle line of the pipe wall of the barrel of the pipe, in.
W = ordinary supporting strength of the pipe, calculated as described in the preceding paragraphs, lb. per lin. ft. of pipe.
F = modulus of rupture of the pipe, lb. per sq. in.
t = average thickness of the pipe wall of the barrel of the pipe in inches at either the top or the bottom, the lesser value being used.

In computing M, for "sand" bearings add 5/8 of the weight of the pipe per linear foot to W, provided such addition exceeds 5 per cent of W. For "two-point" or "three-point" bearings add 3/4 of the weight of the pipe. (*Western Engineering*, vol. 9, no. 2, February 1918, pp. 57-59, 2 tables.)

SEVEN-YEAR TESTS SHOWING THE EFFECT OF AGE AND CURING CONDITIONS ON THE STRENGTH OF CONCRETE, M. O. Withey. In this investigation it has been found that the more pronounced variations in the strengths of the neat-cement test pieces are due largely to the embrittling of the specimens with age. Furthermore, neat-cement specimens stored in air are probably much more weakened due to surface defects than are mortar or concrete test pieces stored under similar conditions. The major portion of the strength of concrete appears to be secured at an age of six months to one year. At the age of seven years water-cured concrete is slightly stronger than concrete cured out of doors and considerably stronger than concrete cured in the cellar.

It has been found that the effect of differences in the humidity of the storage condition is much more pronounced at the age of seven years than it is at the age of six months, which emphasizes the importance of maintaining the water contained in the concrete at all ages if maximum strength is to be secured. (*The Wisconsin Engineer*, vol. 22, no. 5, February 1918, pp. 183-188, 2 figs., 1 table.)

ANNEALING OF CARBON STEELS, R. B. Fehr. *The Pennsylvania State College Bulletin*, vol. 11, no. 11, October 1, 1917, pp. 81-101, 7 figs., 6 tables.

LA DURETÉ DES ALLIAGES MÉTALLIQUES INDUSTRIELS, P. Ludwik. *La Technique Moderne*, tome 10, no. 1, January 1918, pp. 30-33, 5 figs., 5 tables. Deals with the hardness of industrial metal alloys.

WIRE ROPE FOR AIRCRAFT. Discussion of the properties of wire rope for aircraft and certain special methods resorted to in order to give it the desired properties.

Wire rope is frequently the weakest link in otherwise strong engineering structures. It is claimed that elasticity is fully as important as tensile strength, and a tensile test alone is not sufficient for judging the wire. There is a possibility that in the future a simple form of streamline fairing will be developed, which will eliminate the so-called vibrant strains. Fairing reduces not only the vibration in the wire, but also the head resistance. In fact, it is claimed that a small wire vibrating rapidly offers as much head resistance as a flat surface, the width of which is equal to the amplitude of the vibration.

All rope specifications should provide for not only torsion, bending and tensile tests of the individual wire after drawing, but also for the material in rod form before drawing, as good wire can only be made from material of proper quality. Further, specifications of wire rope must also specify the elongation.

Hardness may be intensified by very high machine speed in stranding and closing the rope. If the elastic limit is not exceeded in the drawing operation no hardness results, but if the drawing subjects the material to stresses beyond the elastic limit, a certain amount of permanent set is produced and hardness is the result.

Hardness can be kept within reasonable limits in three ways: viz., first, by giving careful heat treatment during manufacture; second, by carefully drawing down the wire by quarter to half sizes; and third, by using moderate speed for stranding and closing the rope. A certain amount of hardness is desirable because a given hard-drawn steel wire will support

a heavier load than untreated steel, but increased tenacity is obtained at the expense of elasticity and may be carried to the point where the material becomes dangerously brittle. Fig. 1 shows how hardening the material raises its tensile strength and reduces its plasticity. The relation between Brinell hardness numbers and the tensile strength of drawn steel is expressed by the following equation:

Tensile strength, tons per sq. in. $= 0.213 \times$ Brinell number $+ 5$.

Certain tests of wire rope in rod form and finished form are recommended. (*Aeronautical Engineering*, January 9, 1918, abstracted through *Automotive Industries*, vol. 38, no. 7, February 14, 1918, pp. 366-367, 3 figs., *p*)

Fuel and Firing

Storage and Weathering of Coal, W. D. Stuckenberg and J. F. Kohout. The question of storage of coal becomes of particular importance at the present time, when it may be possible that large consumers will have to accept their coal in equal monthly shipments, or receive a large share of it during the summer months, so as to relieve possible future railroad congestion.

Broadly speaking, the larger sizes of coal from about No. 3 nut on up through the various sizes of nut, egg and lump store without giving any trouble. Anthracite and semi-bituminous coals store well in any size. Black lignite or sub-bituminous coal from the West is hardly suitable for storage.

Difficult to store are the finer sizes of coal, which are used principally for power purposes; these are generally high in moisture and iron pyrites, and also, because of their smaller sizes, expose a great number of small surfaces to the air. These several factors all tend to initiate oxidation and to speed it along once it has started. Eastern coals are purer and lower in moisture and pyrite than western coals.

The speakers discussed in detail the conditions producing oxidation and rise of the temperature of the coal pile. In this connection they claim that the effect of external sources of heat is of extreme importance. In fact, without the aid of heat from some external source, the initial stages of oxidation either would not appear or their rate would be extremely slow. These sources of heat may be steam pipes in the ground or near the pile, or heat from boilers, especially in the case of bunkers on vessels. When coal is unloaded by dumping on the ground from a car or a high trestle, and then is piled up to almost the level of the car floor, as is frequently done in coal yards, the heat of impact and of pressure constitutes a positive danger to the coal.

Absorption of heat from the sun will also raise the temperature of the coal to a surprising degree. In the case of a certain shipment from a plant in Indiana, the coal carried a rather large amount of moisture and pyrite, but was taken out of the ground only about ten days before delivery. When received it was so warm that the hand could not be kept in contact with it for more than a few seconds. The reason for this was discovered to be the fact that it was shipped in steel cars, which stood on sidetracks exposed to the direct rays of the sun for about two days. If this coal had been placed in storage in the condition in which it was received, it would certainly have fired spontaneously in a short time. (Paper read before the Kentucky Ice Manufacturers' Association, abstracted through *Power*, vol. 47, no. 7, February 12, 1918, pp. 234-235, *p*)

A New Method of Burning Powdered Coal. Description of a fuel system in which the fuel is delivered from the pulverizing plant to the point of combustion by means of air pressure in distinction from systems in which continuous helical-screw conveyors are used, or systems in which the coal is carried by high-velocity air with the coal dust in suspension.

This new system has been applied to the plant of Dilworth, Porter & Co., Inc., Pittsburgh, Pa. The plant is noteworthy for the distances which the powdered fuel has to be carried, for the large size of the furnace, and for the type of feed control. It is of interest to note that the present equipment has replaced natural gas and that it has been operating with complete success throughout the recent severely cold weather.

The present scheme of conveying coal is based on the fact that powdered fuel when thoroughly dry acts as a fluid and thus allows for using piping of long length at any necessary tilt or angle. The powdered coal collected in tanks at the pulverizing station is subjected to air pressure in the upper part of the tanks and forced as needed from the bottom of the tank through the coal-delivery or transport pipes. Coal has thus been delivered for a length of 1500 ft., at a speed depending in part upon the air pressure. For example, 4 tons have been actually carried through a 550-ft. line in 5 min. with air at 40 lb. gage pressure. The coal is pulverized to pass 95 per cent through a 100-mesh sieve and 85 per cent through a 200-mesh sieve.

To introduce the powdered fuel into the air-transport system proper two blowing tanks are provided, each of a capacity of 5 tons per charge. Compressed air is supplied by a two-stage motor-driven air compressor fitted with feather valves which delivers into air receivers from which the air is admitted to the blowing tanks. An aftercooler is provided to remove moisture from the air as it leaves the compressor, as well as cool the air as it is being stored. In the head of the blowing tank there is a valve operated from the floor and controlling the flow of coal into each tank as well as preventing the escape of air when closed.

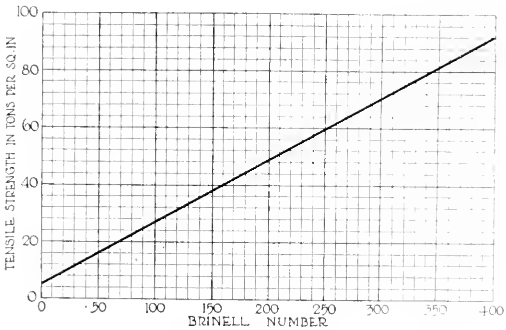

Fig. 1 Curve Showing Tensile Strength as a Function of Brinell Hardness

The powdered coal is directed into bins at the furnace when required by means of special switching valves operated from the floor by the hopper conveyor. The hoppers vary from 1 to 8 tons in capacity according to the furnace consumption.

Fig. 2 shows the plan of the air-transport system to the several groups of heating surfaces. The scale indicates the long distances traversed from the powdered-coal mill to the furnace. It is of interest to note that the transport lines through which the powdered coal is brought are 4 in. in diameter throughout the plant. It is believed that this fact is conducive to greater economy, as compared with screw conveyors or large-cross-section air mains now in use.

To regulate the powdered coal fed to the furnace, controllers are provided at the bottom of the hopper, one for each burner (Fig 3). The controller consists of a cast-iron hopper casting bolted to the opening with a spiral screw which feeds the fuel accurately to a cast-iron screen housing spaced from the hopper casting by a steel pipe. At the front of the hopper casting the thread of the spiral screw is interrupted in order to admit of the movement of two simultaneously operated gates controlled by levers on the outside, which regulate the amount of coal carried to the burners by varying the gate opening. By this device exact feed of fuel is accomplished, and it is stated that a controller of 500-tons-of-coal-per-hour capacity has been adjusted to feed a minimum of 26 lb. per hour.

The burner is composed of a large cast-iron pipe with a specially shaped elbow. The coal-dust pipe is concentric

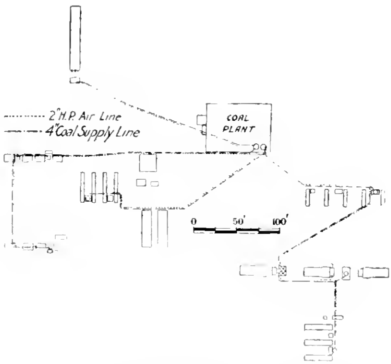

Fig. 2 Plan of Air-Transport System to Several Groups of Heating Furnaces

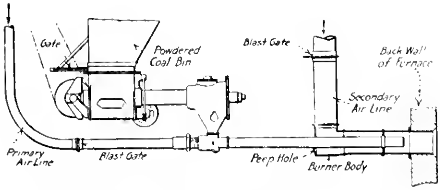

Fig. 3 Apparatus for Regulating Fuel Fed into Burner

within it and extends almost to the furnace wall. The air for combustion enters through the elbow under 1.25 oz. pressure, and the air transporting the coal under a pressure of 6 oz. expands down to 1.25 oz., mingling with the combustion air at that pressure as it burns.

The furnace temperature is regulated by the amount of coal passed into the burner through the gate controller and by the quantity of air. It is stated that air firing at the low pressure of 1.25 oz. is desirable as it reduces the abrasive action on the brickwork. (*The Iron Age*, vol. 101, no. 9, February 28, 1918, pp. 545-549, 7 figs., *e*)

The Melting Point of Coal Ash, J. T. Dunn. A brief report of a highly interesting investigation giving the melting points of a number of ashes.

It has been found that the melting point of ashes is essentially determined by the quantity of basic oxides, especially alumina and silica, and the molecular weight of same, so that if one adds to the given mixture of alumina and silica a quantity of another metallic oxide the amount by which the melting point is lowered is almost independent of the nature of the material, provided its quantity is proportionate to its molecular weight; and that if a number of different oxides are mixed together with the alumina and silica mixture at the same time, the reduction of the melting point depends upon the number of molecules of the oxides which have been added to the given number of molecules of alumina and silica. (*Journal of the Society of Chemical Industry,* vol. 37, no. 1, January 15, 1918, pp. 15 T-16 T.)

Testing and Standardization of Motor Fuel, E. Lawson Lomax. The writer begins by giving an interesting classification of the hydrocarbons present in motor fuel. He proceeds then to the description and discussion of comparative merits of testing. In connection with the determination of the boiling point he thus discusses the methods of Sir Boverton Redwood and a modification of the Engler method for the valuation of crude petroleum, and also submits his own method, which combines the ease of manipulation of the Redwood test with the precision of the Engler test.

He also describes a method for approximately determining the sulphur compounds in the fuel, a matter of importance, because sulphur frequently reacts with the metal of the carburetor.

The determination of the hydrocarbon characteristics is discussed in considerable detail; while in connection with the determination of the spontaneous-ignition temperature only, the Moore method is described, which is a test consisting of allowing one drop of the fuel to fall into a platinum crucible heated to a desired temperature and observing whether an explosion occurs. Hydraulics

Determination of the Duty of Water by Analytical Experiment, W. C. Hammatt. The purpose of the paper is to show a method used in the determination of the quantity of water required for the growth of certain crops, where it is impracticable to measure it directly. In this case it was desired to determine the duty of water for the propagation of certain wild grasses in southeastern Oregon, under conditions making it impracticable to segregate certain measured areas and determine the actual use of water. Therefore some other method had to be devised, and the analytic method was selected as probably the best.

This method consisted in dividing the water into its various uses and making a separate determination, as far as possible, of each use. In this manner any of the determinations which were based on estimates, or for which the data were inadequate or unreliable, would affect only the particular item concerned, and not the whole duty of water. Also, by a study of different factors making up the analysis, it is believed that unnecessary or reparable losses may be discovered.

In this case the water was to be used for plant growth. In a strict sense the only water actually so used is that taken in through the roots and either remaining as a component part of the plant or evaporated through its leaves. However, it is impossible to deliver water to the roots directly, and as the water has to pass through the soil, both on its way to the plant and in order to pick up the salts necessary for plant growth, the uses of water are subdivided into the following four classes: (1) Soil moisture; (2) Soil evaporation; (3) Plant use; (4) Soil losses.

The writer proceeds to the analysis of each one of these items in a manner which cannot be reported here through lack of space.

The writer claims that while the method here described is not always superior to that of direct trial, it is useful in cases where the latter is impracticable, and even where direct trial is possible it may be used as a check on the economy of consumption of water for irrigation purposes. (Paper presented on March 20, 1918, before the American Society of Civil Engineers, abstracted from *Proceedings of the American Society of Civil Engineers*, vol. 44, no. 2, February 1918, pp. 307-357, 23 figs., *ep*)

Lubrication

Lubrication of Ball Bearings, Otto Bruenauer. The present article begins by setting forth the principal characteristics of oils and greases such as may be used for lubrication of bearings, especially ball bearings, and then proceeds to the description of various types of designs for grease, oil and dirt-proof houses. The article, which is apparently the beginning of a series, is liberally illustrated and is of considerable practical interest.

As regards the intervals at which the ball bearings must be lubricated, the writer states that in shaft hangers, in industrial motors, wheel hubs, gear cases, pumps and machines operating under similar conditions a fresh charge of lubricant twice a year is ample and in some cases once a year will be found sufficient. Exposure of the machine to heat will make more frequent lubrication necessary. Also for railway motors, journals and such machines as are constantly exposed to the influence of weather and outdoor conditions a fresh charge of lubricant four to six times a year is recommended. Measurements

Measuring High Pressures with Dead Weight. Sanford A. Moss, Mem.Am.Soc.M.E. Description of the use of a dead-weight pressure-gage tester for measuring pressures during tests, as used in the Steam Turbine Department of the General Electric Company, Lynn, Mass.

The difficulty with Bourdon pressure gages when extreme accuracy is desired, is that frequently the calibrations before and after the test disagree, and even where the calibrations do agree there is often a question as to whether the temperature effect has been properly taken care of. In addition, most Bourdon gages are not accurate to one per cent, and therefore have to be read by estimation between the graduations.

The dead-weight pressure gage consists of an accurately bored cylinder, usually having an area of 1/8 sq. in., with a closely fitting piston, at the top of which is a platform on which are placed weights sufficient to keep the gage floating. For use in direct measurement of pressure a stop must be added to prevent the piston from rising out of the cylinder, and an oil trap and reservoir, so that there should at all times be oil in contact with the cylinder and piston. The platform and piston must always be spun by hand when the apparatus is in use.

This gage when attached directly to the pipe where pressure is being measured gives without any difficulty whatever readings accurate to within 0.25 of one per cent. Fig. 4 shows the

apparatus used in the Turbine Department of the General Electric Company's works at Lynn, Mass., where there are about fifteen outfits, all in more or less regular use. Fig. 5 gives a sectional view through the dead-weight pressure gage.

The writer describes in detail several measurements where the dead-weight pressure gage is used. He states in particular that in orifice tests of pumps for air compressors it is necessary to have two dead-weight gages; or one dead-weight gage and one mercury column, since there are two distinct pressures. One of these is a discharge pressure measured in the pipe between the throttle valve and the machine; it gives

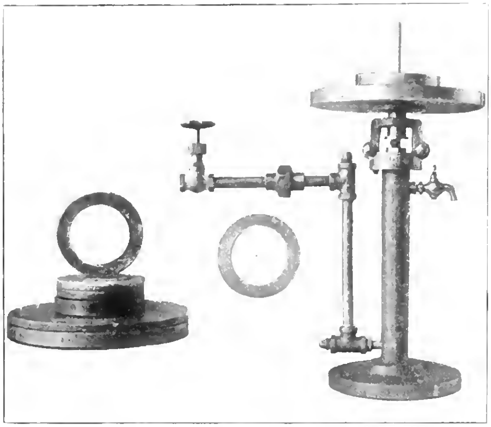

FIG. 4 DEAD WEIGHT PRESSURE GAGE

the pressure with which the machine is to be credited in computing performance, efficiency, etc. The throttle valve cuts down this pressure so that any desired pressure can be had on the orifice, the volume or amount of flow being computed from the orifice pressure. This orifice pressure may be measured by means of a static hole in the pipe wall with the pipe connecting to the dead-weight gage or mercury column, or an impact tube may be used on the jet discharged from the orifice, as explained in a paper by the author, entitled The Impact Tube (Trans.Am.Soc.M.E., December 1916).

When, in the test with the dead-weight gage, the pressure variation is such as to require constant adjustment by an attendant, a throttle valve must be provided at a convenient location and the gage must be piped nearby. The attendant then has one hand on the throttle valve and with the other hand spins the dead weight gage. The purpose of this spinning is to keep the gage floating.

The writer gives two tables from which the necessary corrections in the readings may be made, as well as directions to avoid errors in readings. (*Power*, vol. 47, no. 9, February 26, 1918, pp. 286-288, 3 figs., *dA*)

NEW "TOTAL IMMERSION" HYDROMETER, A. Ångstrom and H. Pettersson. (*Zeits. Instrumentenk*, 37, pp. 177-180, September, 1917). To a glass bulb, weighted with shot, and of about 25 cm. external volume, is attached a fine chain about 40 cm. long. The chain is made of doubly-gilded brass and contains about 500 links of equal weight. When a bulb and chain are put into a glass cylinder containing a liquid of such density that the bulb is totally immersed, the bulb will sink in the liquid and the chain will coil up on the bottom of the cylinder until a position of equilibrium is reached. The cylinder containing the liquid is so graduated that the density of the liquid in it can be determined from the position of the pointed upper end of the glass bulb. It is shown that the maximum error in the density is less than the accuracy with which the divisions on the cylinder can be read, the average error not exceeding 0.02 per cent. If the bulb is made of quartz, the chain of gold, and a Dewar vacuum vessel is used to contain the liquid, an accuracy of about 0.002 per cent can be obtained. It is convenient to have a glass cylinder with a false bottom on which the chain coils up. The bottom of the cylinder is drawn out to a tube and fitted with rubber tubing and clip so that the liquid can be conveniently run out. FLOW MEASUREMENT IN A WATER COLLECTING GALLERY BY THE CHEMICAL METHOD, D. H. Maxwell. *Journal of the American Water Works Association*, vol. 4, no. 2, June 1917, pp. 192-199, 3 figs.

Mechanics

HOW TO PROPORTION UNSYMMETRICAL CONCRETE ARCHES, Jos. P. Schwada. The writer develops a method and formula for determining the dimensions of the two halves of an unsymmetrical concrete arch.

One of the steps in the design of an unsymmetrical concrete arch is the proportioning of the arch ring. This consists of the determination of the position of the crown with respect

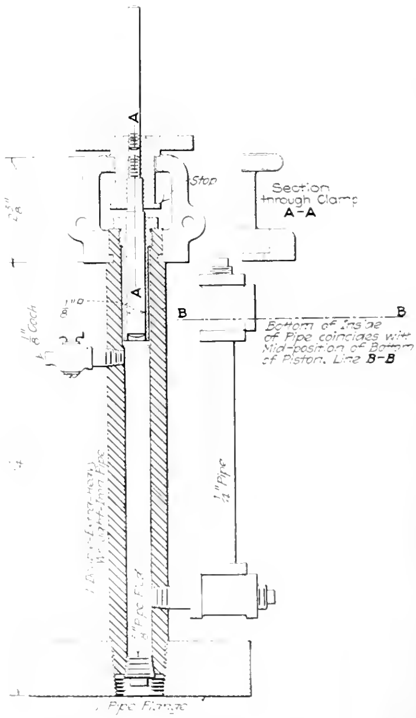

FIG. 5 SECTIONAL VIEW THROUGH DEAD-WEIGHT PRESSURE GAGE

to the springing lines and the selection of a proper crown thickness, the curvature of the arch axis and the thickness of the arch ring from the crown to the springing lines. An empirical method is here offered for determining these dimensions. This method is based on a consideration of an unsymmetrical arch ring as made up of half spans of unequal symmetrical arches, located so that when treated as the half spans of symmetrical arches, the crown thrusts for dead load only will be equal. Hence, the position of the crown will be at the point of zero shear, and the crown thickness, curvature of the arch axis and the thickness of the arch ring may be obtained as for symmetrical arches.

The writer derives an expression for the length of the shorter segment of the unsymmetrical arch of given span, and also an expression for the other determining magnitudes. A comparison between the crown thrust for a given unsymmetrical arch determined according to the elastic theory, and the crown thrust for the symmetrical arches, with half spans equal to the segments of the unsymmetrical arch, determined according to both the empirical formula and the elastic theory, shows the general reasonable correctness of the empirical formulæ. (*Engineering News-Record*, vol. 80, no. 9, February 28, 1918, pp. 415-416, 3 figs., *pe*)

Studies of Liquid Films, Sir James Dewar. Last year Sir James Dewar delivered a lecture before the Royal Institution on liquid films (soap bubbles), and showed the great importance of research in this direction. He pointed out at the time that the work was threatened by the restriction of the departmental staff. While his two men actually remained in with him, the research was frequently interrupted.

The speaker explained the manner of blowing the soap bubbles and means for prolonging their life, the most important in this latter respect being the absence of dust, and especially of greasy dust specks. He further explained the mechanics of the bubble: namely, thinning of the film through the draining off of the liquid of the bubble and the condensation of water vapor on the film, resulting in the washing out of the soap.

The gas pressure inside the bubble was always a little greater than the pressure outside. Owing to the surface tension, the bubbles contracted and the gas was forced outward through the film.

In order to produce large bubbles of long life, the speaker attempted to purify one of the cellars of a building of all dust and blow bubbles from outside through the wall. The cool, steady temperature of such a space was supposed to be an advantage. Actually, however, the attempts failed. Yet Sir James succeeded in producing films, one half black and another wholly black, in a bottle about a foot and a half in diameter. One of these films lived for 56 days, in spite of all the vibrations of the laboratory.

Two methods have been applied to prevent the spontaneous contraction of a bubble and to prolong its life. One is to replenish the gas forced out of the bubble, and the other to produce the bubble in a high-pressure atmosphere, so as to have a high pressure both inside and outside of the bubble. Thus, in the case of a bubble in a glass vessel at ten atmospheres pressure, ten times the amount of gas would have to get through the film to produce the same contraction as would result in a container at atmospheric pressure, while in a container at 100 atmospheres the bubble would practically be permanent. Rates of transference of hydrogen through bubbles under a pressure of 1 atmosphere and 6.5 atmospheres were determined.

Sir James also made numerous experiments on the production of chains of bubbles, showing how bubbles united. One of the ways of determining this was as follows:

By forcing air through a tube he produced a soap bubble on a plate of glass smeared with glycerine, the bubble being more or less hemispherical. When a second bubble was planted next to the first, the second united with a plane common face; a third bubble added led to the formation of three common faces meeting at 120 deg., and so on. When the plate was illuminated from below to show the arrangement in the plan, it was seen that five bubbles would group themselves about a pentagon; six bubbles would form a hexagon, etc. When the plate was blown upon, the films collapsed and flattened out, but the geometric pattern remained discernible for a few moments.

In another series of tests, a chain of bubbles was suspended from a tube forming quite interesting structures, including catenaries of strange complexity built up of multitudes of bubbles in regular patterns. For example, an inclined catenary in which photographs of natural colors showed both the spherical and the color plane faces. (Lecture before the Royal Institution, January 18, 1918, abstracted through *Engineering*, vol. 105, no. 2717, January 25, 1918, pp. 98-99, 1 fig., *etA*)

Discussion of some new formulæ in metallurgy. The present investigation is based on the formula developed just before the war by the Russian metallurgist, Prof. Groun Grzimailo. On the basis of this formula the writer has developed a new type of blast furnace.

Motor-Car Engineering

Principles of Tractor-Engine Cooling, Arthur B. Modine. Discussion of the factors involved in tractor-engine cooling. While the paper is specifically devoted to tractor engines, it discusses the subject in a broad manner, which makes it fully applicable to the case of motor-engine cooling generally.

The principal variables affecting the cooling in addition to the radiator size pertain to radiator type, radiator core, thickness or degree of cooling capacity, rate of water circulation, size, type and speed of fans, and the economic characteristics of the engine to be cooled.

It is obvious that in order that the cooling should be efficient, the air has to be capable of taking away the heat delivered in the water to the radiator. This heat to the radiator, as the author states in his introductory formula, is equal to heat input minus heat equivalent of horsepower developed and

heat losses, which he divides into two groups, viz.: exhaust loss, and engine radiation and convection losses.

The following equation is given as derived from observed average performances:

$$\text{Heat to radiator} = 0.40 \times \text{heat input} \times F$$

where F is a variable with the value of 1.0 in the case of L-head engines ranging from 25 to 50 hp. and 0.8 in the case of valve-in-head engines of the same power range, both values applicable to tractors. The writer shows further that in the case of a tractor, the heat loss to the radiator per minute per horsepower is equal to about 100 B.t.u. It may be stated here that the average heat loss to the radiator in motor-car engine design is assumed to vary from 50 to 60 B.t.u. per min. per hp.

The writer derives the following formula for the frontal area of the radiator in sq. ft. per hp. output of the engine:

$$\text{Area} = \frac{6000}{v(T_1 - T_2)}$$

where v is the air velocity in ft. per min. and $T_1 - T_2$ is the temperature rise of air (in deg. fahr.) due to its passage through the radiator.

This indicates that for a given radiator the problem of cooling resolves itself into two factors—the temperature rise of the air and the velocity of the air.

The writer considers the subject of temperature rise in its relation only to two variables—rate of water delivery and air velocity; and shows, first, that the velocity of flow of water through the radiator is of very great importance, the faster flow producing much better cooling; and second, that the heat taken up by convection by air increases nearly directly in proportion to the velocity.

The paper presents also an interesting discussion as to fan power requirements, and presents a plea for larger fans and slower speeds than those in present average practice. (*Journal of the Society of Automotive Engineers*, vol. 2, no. 2, February 1918, pp. 148-151, 4 figs., *et*)

Munitions

Formulæ for Trajectories of Anti-Aircraft Shells, G. Manetti. The formulæ used in the present article are expressed in the notation used in the works on ballistics by Siacci and by Ronca, published in Italy. These works are not available in the Library of the Engineering Societies.

Consider the two trajectories in Fig. 6, such that $X = W$, $OC = OD$ and the initial velocity V is the the same in both cases. Then from the equations cited by Ronca, the writer deduces the following equations:

$$X = \frac{V^2 \sin 2\phi_r}{g} G_y(Z) \ldots\ldots\ldots\ldots\ldots [1]$$

$$W = 2V^2 \frac{\cos(\varepsilon + \alpha)\sin\alpha}{g\cos^2\varepsilon} G_y(z) \ldots\ldots\ldots [2]$$

From the condition stated above, namely, $OD = OC$, the writer deduces $OB = x = X\cos\varepsilon$, but knowing that approximately $\beta = \sec\phi$, he further deduces that the ballistic coefficient of the trajectory OC is equal to the ballistic coefficient of OD multiplied by the same $\cos\phi$. Hence, $z = Z$, and $G_y(z) = G_y(Z)$.

After simple reductions the following formula is obtained:

$$\sin 2\phi_x = \frac{2\cos(\varepsilon - \alpha)\sin\alpha}{\cos^2\varepsilon} \ldots\ldots\ldots\ldots [3]$$

and by an analogous method, assuming that T_w represents the duration corresponding to W, he obtains

$$T_w = T \cdot \frac{\cos\varepsilon\cos\alpha}{\cos(\varepsilon + \phi_x)} \ldots\ldots\ldots\ldots\ldots [4]$$

These are the formulæ which have already been deduced by another method, namely, by a consideration of the analogy with motion in vacuum by Obermeyer, Schmidt, Clausen and others, together with the following formula which is correct only for vacuum:

$$\tan\theta = \tan(\varepsilon + \alpha)\frac{\sin 2\phi_x \cos\varepsilon}{\cos^2(\varepsilon + \alpha)} \ldots\ldots\ldots [5]$$

But knowing that $\nu = \varepsilon - \theta$, Clausen advises to substitute the value of the angle of arrival of the aerial trajectory when ν is calculated by these vacuum formulæ and to multiply the result by ϕ_x, ω_x, a procedure which has no analytic justification, but is permissible in an approximate calculation. (Compare *Journal of the United States Artillery*, November-December 1916).

The preceding formulæ represent the best approximative solution of the problem of anti-aircraft ballistics, because of their marked simplicity, and in computations give sufficiently satisfactory results, which may be improved to any desired degree by means of the following methods:

From [3] it is easy to obtain equation

$$\frac{2d\phi_x}{\tan 2\phi_x} = \left[\frac{1}{\tan\alpha} - \tan(\varepsilon + \alpha)\right] d\alpha \ldots\ldots\ldots [6]$$

a formula to the application of which it is possible to give a precision equal to that which is secured with its integral. This can be proved in the same manner as has already been done with respect to the function G. Since it is known that $\frac{2d\phi_x}{\tan 2\phi_x} = \frac{\tan\omega_r}{\tan\phi_x}\frac{dX}{X}$, which is true because by assumption $X = W$, and hence $dX = dW$, we have

$$\frac{\tan\omega_r}{\tan\phi_x}\frac{dW}{W} = \frac{1}{\tan\alpha} - \tan(\varepsilon + \alpha)d\alpha \ldots\ldots\ldots [7]$$

which is the differential equation of projection on the plane and is of great value in the calculation of tables of fire.

From the equality of $G(z) = G(Z)$ is derived also the equality of their partial derivatives $\frac{\partial G}{\partial V} = \frac{\partial G}{\partial \frac{x}{G}}$ and hence by the usual differentiations of [1] and [2] it is easy to prove that approximately the following two equations always hold good:

$$\frac{\partial W}{\partial V} = \frac{\partial X}{\partial V} \ldots\ldots\ldots\ldots\ldots\ldots [8]$$

$$\frac{\partial W}{\partial C'} = \frac{\partial X}{\partial C'} \ldots\ldots\ldots\ldots\ldots\ldots [8a]$$

These equations are of the greatest utility for direct application and still more for purposes indicated below.

It is known that

$$\frac{\tan\omega_r}{\tan\phi_r}\frac{dX}{X} = \frac{2d\phi_r}{\tan 2\phi_r} + \frac{\tan\omega_r - \tan\phi_x}{\tan\phi_r}\frac{dC'}{C'}$$

Knowing that

$$\frac{2d\phi_x}{\tan 2\phi_x} = \frac{\tan\omega_x - \tan\phi_x}{\tan\phi_x}\,\frac{d\delta}{\delta}$$

and introducing this value into Equation [6], we obtain

$$\frac{\tan\omega_x - \tan\phi_x}{\tan\phi_x}\,\frac{d\delta}{\delta} = \left[\frac{1}{\tan\alpha} - \tan(\varepsilon+\alpha)\right]d\alpha$$

which permits improving the result obtained by the application of [3] (which may be done in practice by using a nomographic slide rule) by applying the angles of elevation directly in order to take care of the variation of density in the vertical direction.

Professor Fubini has succeeded in an original and ingenious manner to establish the following equations:

$$d\phi = g\,\frac{dy - \tan\theta\,dx}{V^2(\tan\phi - \tan\theta) + \frac{\partial x}{\partial V}\tan\theta\left(g\tan\phi + \frac{\delta i}{C}F(V)\frac{1}{\cos\phi}\right)}$$

from which we get by writing $dy = 0$, ...[9]

$$V^2\left(1-\frac{\tan\phi}{\tan\theta}\right) = g\,\frac{\partial x}{\partial\phi} + \frac{\partial x}{\partial V}\,V\left(g\tan\phi + \frac{\delta i}{C}\,\frac{F(V)}{\cos\phi}\right).\ [10]$$

By using the same method the present writer succeeded in obtaining

$$V^2\left(\frac{\sin\alpha}{\tan\nu} - \cos\alpha\right) = g\cos\phi\,\frac{\partial W}{\partial\alpha} + V\left(g\sin\phi + cf(V)\right)\frac{\partial W}{\partial V}$$

........[11]

in which the ballistic coefficiency for the sake of convenience in anti-aircraft fire calculations is, contrary to the usual practice, expressed by the following equation:

$$c = 0.896\,\frac{a^2}{p}\,\delta_m i$$

where δ_m is the average density; 0.896 i is the "form" coefficient as applied to a projectile of the type having a complete ogive of two radial calibers.

The three formulæ, [9], [10] and [11], are of the greatest utility for purposes of calculation.

In tables of anti-aircraft firing preëminent importance must be given to fuse timing. Hence, while the above formulæ may be considered to have the same values as if they were expressing at the same time a formal solution of problems of anti-aircraft ballistics, they cannot be correctly applied to the case of formula [4]; that is, to the calculation of all "time" elements.

In the Italian *Rivista di Artiglieria e Genio* two papers concerning the above matter were published in 1916 and 1917, first by the author and then by the well-known artillerist, Bianci. In the present article the author proceeds to give a more simple and direct solution than any given in the two papers cited above.

If we consider that at P, Fig. 7, is projected some point of an anti-aircraft trajectory which is being calculated, then by adhering to the hypothesis of direct resistance and by applying the Siacci formulæ for retardation as given in Ronca's Ballistica (in formulæ 54 on p. 149), and finally by resolving the force of gravity into two forces—one parallel to, and the other at right angles to, the direction of motion, the writer applies the principle of conservation of energy and obtains

$$\frac{dv}{dt} = \frac{vdv}{ds} = -cf(v) - g\sin\theta$$

and for centripetal acceleration

$$\frac{v^2}{\rho} = \frac{v^2 d\theta}{ds} = -g\cos\theta$$

where ρ is the radius of curvature. From this we easily deduce

$$ds = \frac{-vdv}{g\sin\theta + cf(v)}$$

$$dt = \frac{-dv}{g\sin\theta + cf(v)}$$

$$d\theta = \cos\theta\,\frac{gdv}{v[g\sin\theta + cf(v)]}$$

Substituting for $\frac{c}{\sin\theta}$ the expression, $c_1 = \frac{c}{\sin\theta_m}$ where θ_m is the average value of θ, we obtain

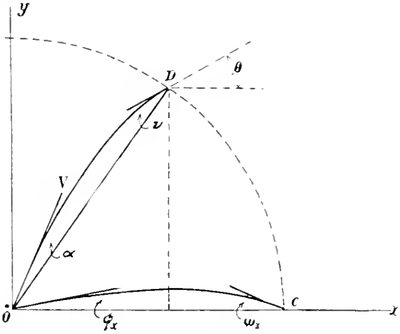

FIG. 6 TRAJECTORIES OF ANTI-AIRCRAFT SHELLS HAVING THE SAME INITIAL VELOCITY

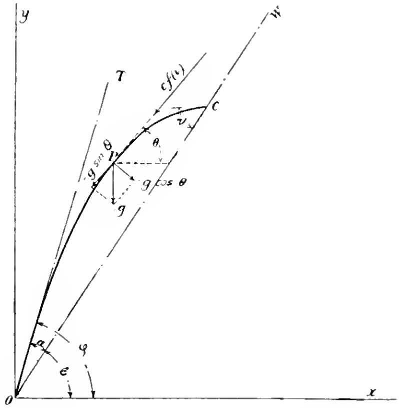

FIG. 7 ANTI-AIRCRAFT SHELL TRAJECTORY

$$\log_e\frac{\cos\theta}{\cos\phi} = \int_V^v \frac{-gdv}{v[g + c_1 f(v)]}$$

Then, using the notation

$$B(v) = \int_v^{1200}\frac{gdv}{v[g + c_1 f(v)]}$$

and further using the notation $e^{B(v)} = I(v)$, the writer obtains

$$\cos\theta = \cos\phi\,\frac{I(v)}{I(V)}$$

Likewise it is easy to deduce

$$s = \frac{1}{\sin\theta_m}\left[S(v) - S(V)\right]$$

$$t = \frac{1}{\sin\theta_m}\left[T(v) - T(V)\right]$$

where

$$S(v) = \int_{v}^{1200} \frac{v\,dv}{g + c_1 f(v)}$$

$$T(v) = \int_{v}^{1200} \frac{dv}{g + c_1 f(v)}$$

Now, since $dy = \sin\theta ds$ and $dx = \cos\theta ds$
we have $y = \sin\theta_m s$

$$\text{and } dx = \cos\phi \frac{I(v)}{I(V)} \frac{v\,dv}{g \sin\theta + c f(v)}$$

and hence

$$x = \frac{\cos\phi}{I(V)} \frac{1}{\sin\theta_m} \left[A(v) - A(V) \right]$$

where

$$A(v) = \int_{v}^{1200} \frac{I(v)\,v\,dv}{g + c_1 f(v)}$$

There is no difficulty in calculating and tabulating with respect to v and c_1 the functions I, A, S and T, and this will give a complete solution of the problem provided the method of calculating the average function $\sin\theta_m$ be given.

The writer considers it unnecessary to try to solve this far more difficult part of the problem, since, from a practical point of view, the results would be of little value. As a matter of fact, tables can be constructed so as to make the interpolation very easy, and it is always possible in practice to use such a subdivision as would make it possible to give with reasonable correctness to $\sin\theta_m$ such a value that the function $\sin\theta$ may apply to the origin of the required arc. Railroad Engineering

Electric Boiler Heating for Steam Locomotives, W. Kummer. (*Schweiz. Bauzeitung*, 1917. *Elektrot. u. Maschinenbau*, 35, pp. 434-435, Sept. 9, 1917. Abstract). This article suggests that electric boiler heating offers economic advantages on Swiss steam railways; there are also criticisms by other writers. Kummer considers that electric heating can compete with coal firing for boilers at the present price of coal in Switzerland. Any kind of current may be employed so long as it is transmitted at high enough pressure. The accompanying table gives data for three types of Swiss steam railways referred to traffic in ton-km. (total weight).

Assuming feedwater at 30 deg. cent., the heat expenditure for steam as used on locomotives averages 635 kg-cal. per kg. for saturated steam and 700 kg-cal. per kg. for superheated steam. On the basis of 1 kg-cal. = 1.16 watt-hr., and allowing 86 per cent efficiency for saturated steam or 81 per cent for superheated steam between the line feeding point and the steam

raised, we have an energy consumption of 857 watt-hr. per kg. with saturated steam, and 1000 watt-hr. per kg. with superheated steam. Lines 3 (*a*), (*b*) in the table show the much higher efficiency of direct electric drive, compared with electric heating of steam boilers. Lines 4 (*a*), (*b*) are based on lines (1) and (3), and on coal at 100 fr. per ton and electrical energy at 1.5 Rp. per kw-hr. Under these conditions electric heating is 10 per cent cheaper than coal firing. Allowing 0.043 to 0.055 Rp. per ton-km. for working line costs, and from 0.015 to 0.01 Rp. per ton-km. for the conversion of steam locomotives to electric heating, the cost of electric heating would be practically equal to that of coal firing. Kummer suggests that tests be made on an electric railway with a steam locomotive fitted for electric heating.

	Rhaetian Railway	Gotthard Railway	Swiss Mountain Railways, Circuits 1 to 4
1 Coal consumption, kg. per ton-km.	0.100	0.080	0.075
2 Steam consumption, kg. per ton-km.:			
(*a*) Using saturated steam	0.700	0 560	0.525
(*b*) Using superheated steam	0.600	0.480	0.450
3 Electrical energy at feeding-point of the line, watt-hr. per ton-km.:			
(*a*) Steam boiler heating	600	480	450
(*b*) Direct electric drive	48 1	46 to 47	45 to 46
4 Cost of steam, rappen per ton-km.:			
(*a*) Coal firing	1 00	0 80	0 75
(*b*) Electric boiler heating (excluding working cost for line, and loco. conversion)	0 90	0.72	0 675

L. Thormann criticises the practicability of the proposed system. This writer allows 1 kw-hr. per kg. of steam at working pressure; and an energy consumption with electric boiler-heating equal to about 10 times that with electric locomotives. If there is a heating surface of 250 m.^{2} already available on the locomotive to be converted, approximately another 650 m.^{2} would have to be provided, with a construction weight of 52 tons. Probably the extra weight of the electrically heated boiler would be 60 to 80 tons, excluding transformers, which would probably be necessary, and would add another 80 tons to the dead weight. The crucial point seems to be the heating surface required. Thormann's estimate is much higher than Kummer's, owing partly to his assuming that there is no considerable heat storage, so that the heat equivalent of electrical energy supplied would have to correspond with the instantaneous steam demand. Thormann concludes that the weight of an electrically heated boiler and locomotive would be two or three times that of an ordinary steam locomotive; the former would be costly and increase materially the specific energy consumption, so that energy would have to be obtainable at 1.5 centimes (rappen) per kw.-hr. to compete with coal firing. This price, at the line wire, cannot be realized.

In his reply, Kummer asserts that 2750 kw. at the line would provide 417 hp. at the wheel rim of an electrically heated locomotive, sufficing to propel a total weight of 350 tons at 25 km. per hr. up a 1:100 gradient. Thormann's assumption of 917 m.^{2} heating surface for 1036 hp. (at rim) corresponds to 1.13 hp. per m.^{2}, whereas 4 to 6 hp. per m.^{2} is commonly obtained with locomotive boilers providing saturated steam, and 6 to 8 hp. per m.^{2} with superheated steam. Kummer does not agree that the locomotive weight would be much increased by electric heating; as compared with plain electric drive, the electrically heated boiler would be able to accumulate energy during station stops and while running downhill.

A. Trautweiler suggests that surplus electrical energy if available free, could be used advantageously to preheat feedwater for locomotives up to 90 deg. cent. or so in stationary plants at depots. At a medium-sized depot 250 m.^{3} of feedwater might be required daily for 20 locomotives. If 5000 kw. spare capacity be available for 5 hr. each night at an adjacent power station, this could be utilized (at 80 per cent efficiency) to warm the 250 m.^{3} of feedwater through 70 deg. cent. This would correspond to a saving of 3000 kg. coal per diem. Even on the basis of peace prices for coal, this saving would cover the costs and charges on the preheating equipment. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 1, no. 241, January 31, 1918, pp. 1-2)

A Scientific Study of Railway Track Under Load. Progress report of investigations carried on for a period of over five years by a special joint committee of the American Society of Civil Engineers and the American Railway Engineering Association.

The proper conception of the fundamentals underlying the action of track under load may be had only by considering the track as an elastic structure under load. The wheel loads are applied on the top of the rails; the rails are flexible beams which rest on flexible supports (ties); and the ballast and roadway on which the ties rest are themselves yielding or flexible. Due to the stiffness of the rail and the yielding of its supports, the load from a wheel will be distributed over a number of ties, and the amount of yielding of the supports affects the values of the moments and stresses developed in the rail.

The properties of elasticity and stiffness in the rail, the tie, the ballast and the roadway enter in a complex manner into the development of the stresses in a track structure, the relative stiffness of the various parts affecting the results in any one part. The spacing of the wheels of locomotives and cars longitudinally along the track also influences the division of the load, and hence the value of the stresses developed in rails, ties and ballast.

The method of analysis of track action, which is based on the assumption of a continuous elastic support under the rail, has been found to be the most convenient and most comprehensive in its applications to the present investigation. The assumption of a continuous support in place of tie supports is not an element of serious inaccuracy for the close tie spacing and large rail sections used on the American railroads.

A new term, "modulus of elasticity of rail support," has been introduced to measure the vertical stiffness of the rail support, and may be defined as the pressure per unit of length of each rail required to depress the track one unit. It represents the stiffness and ability to yield of tie, ballast and roadway, but does not involve the stiffness of the rail. As applied to ordinary track, the load on one rail required to depress one tie one unit, divided by the tie spacing, will give the modulus of elasticity of rail support.

The fundamental condition on which the analysis is based is that the track depression at any point and the upper pressure of the rail per unit of length at the same point are directly proportional to each other: in other words, $p = uy$.

The following notation is used here (compare Fig. 8):

P = wheel load on a rail at the point which will be used as the origin of abscissæ

E = modulus of elasticity of steel

I = moment of inertia of section of the rail

y = depression of rail at any point, x, it being assumed that there is no play or backlash in the track; downward displacement of a rail is negative; however, in the applications to track, the ordinary downward depressions of track will be spoken of as positive

p = upward pressure against rail per unit of length of rail at any given point

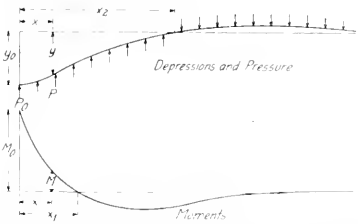

FIG. 8 DISTRIBUTION OF DEPRESSION AND BENDING MOMENT FOR A SINGLE LOAD

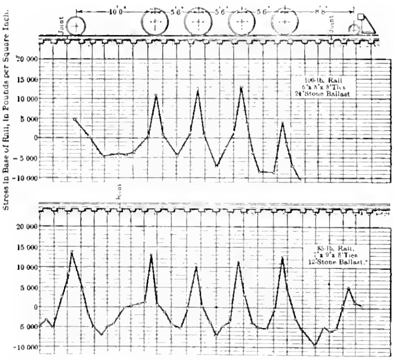

FIG. 9 STRESS-DISTRIBUTION DIAGRAMS FOR STATIC-LOAD TESTS WITH MIKADO LOCOMOTIVE

u = an elastic constant which denotes the pressure per unit of length of each rail necessary to depress the track (rail, tie, ballast and roadway) one unit; for the system of units ordinarily used, it will be expressed in pounds per inch of length of rail required to depress the track 1 in.; u represents the stiffness of the track, and involves conditions of tie, ballast and roadway; it is termed the modulus of elasticity of rail support

M = bending moment in rail at any point.

The formulæ for the bending moment in the rail, the shear and the intensity of the pressure (p) against the rail are obtained from the differential equation of equilibrium of a beam. To find the effect of a combination of wheel loads on the track depressions and the pressures and the bending moment in the rail as may occur with the given type of locomotive, the equations and diagrams for a single wheel load may be applied by the use of the principle of superposition; that is, by considering that at the given point along the rail the combined effect of two or more wheel loads is the algebraic sum of the effects of the individual wheel loads.

Two main types of tests were carried out: namely, static-load tests and moving-load tests. In all moving-load tests, except at very low speeds, steam was shut off as the locomotive approached the test section of the track. It was found that the tractive effort of the locomotive produced an appreciable effect on the rail stresses which was somewhat variable, and it was decided to eliminate this variable when the effect of speed only was studied.

As regards depression of track, little difference was found in the depression for the load over a tie and for the load midway between ties, though both in the one-axle and two-axle loads the depression is generally somewhat greater for the load overhead tie. There is a marked difference, however, in the magnitude of depression, according to the condition of the track, freshly tamped track having a smaller depression under load than track which has been subjected to the action of traffic for a considerable time after surfacing.

Load-stress diagrams for gage lines at the point of application of load in the case of one-axle load and at the points of application of load in the case of two-axle loads were secured and the average of the stresses at the two points being plotted in the latter case. Here again little difference is to be found in the rail stress under the load for a load over a tie and for a load midway between ties, but rail stresses differ noticeably, according to the condition of the track, freshly tamped track giving small stresses. For a rail of 85-lb. section, the stress in rail in an untamped track was found to be as much as 6000 lb. per sq. in. more than in a freshly tamped track.

An interesting series of static-load tests was carried out with a Mikado locomotive on rails of 85-lb. and 100-lb. sections. The static distribution diagrams shown in Fig 9 have been derived from these tests. It is found that the maximum stresses in the rails are directly under the wheels, positive moment being developed at these points and negative moments at points between the wheels. The stress under the inner two drivers and that under the front driver is generally somewhat greater than that under the real driver.

Values of the modulus of elasticity of support were calculated from the track depressions expressed in pounds per inch of rail length necessary to depress the track one inch.

There seems to be some tendency toward a higher value of the modulus in the track having the heavier strain. It is apparent that the character and condition of the track greatly influences the magnitude of the modulus of elasticity of rail support.

Tables were compiled showing the effect of speed as a percentage of the stress in the rail at 5 m.p.h. for each mile-per-hour increase of speed greater than 5 m.p.h. In this connection it appears that heavier rail sections give a somewhat higher proportional increase of stress with increase of speed than the lighter sections; also the heavier rail gives a much higher bending moment coefficient than the lighter. Relation between Efficiency of Refrigerating Plants and the Purity of Their Ammonia Charge, F. W. Frerichs. An extensive experimental investigation in which it is shown that the quality of the ammonia charge has an important bearing upon the operation of the ice plant. In order to minimize considerable losses due to operation of absorption in ice machines with impure ammonia, the writer recommends using liquid anhydrous ammonia of known purity and pure distilled water for charging absorption plants. He calls further attention to the fact that the question of purity of water is of real importance. Steam Engineering

A 50,000 Sq. Ft. Condenser. Description of a surface condenser serving a 30,000-kw. turbine. One of the interesting features of its construction is the use of a special design of expansion joint, shown in Fig. 10. It is 13 ft. in diameter and consists essentially of a fairly close-fitting cast-iron sleeve, so formed as to permit a manometric column of mercury to make a seal to prevent air leakage and at the same time permit of a free motion of the upper and the lower halves of the joint relative to each other. The upper part of the joint is built so that if, for any reason, the mercury arrangement should fail, an ordinary slip joint with soft packing could be used, the place for it being indicated in the figure as "Rope for Packing."

The dotted portion marked "Expansion Joint Clamping Block" at the lower left part of the figure is not used when the joint is in service. It is simply an arrangement whereby the two portions of the joint can be fastened together for shipment, and is removed after the joint is in place.

Some such type of joint was necessary, because the great vertical distance between the condensers and the turbines entailed an extraordinarily great expansion in case the apparatus should be much changed in temperature. The mercury expansion joint can take up an indefinite amount of expansion, whereas a copper joint might ultimately fail with the great distortion necessary. (*Power,* vol. 47, no. 9, February 26, 1918, pp. 282-285, 4 figs., *d*)

The 50,000-Kilovolt-Ampere Connors Creek Turbines. The Connors Creek plant of the Detroit Edison Company was planned to contain six 25,000-kva. machines. Three of them were installed between 1915 and 1917, but when the fourth unit came up for consideration it was found that the development of large turbine units had progressed to such a point that it would be desirable to install a unit of greater capacity than originally planned. Hence, instead of the original contemplated 25,000-kva. units it was decided to install two 50,000-kva. machines, one of which is now being placed.

This turbine is of the disk type. It has twenty-one stages as against nine in the smaller machines, but is only 15 ft. longer overall than are the smaller machines. Other dimensions are also much smaller than one would expect from a direct comparison of capacities. The weight is only about 40 per cent greater than that of the earlier models, while the speed of 1200 r.p.m. is the same.

The small physical size in comparison with the earlier units is partly due to refinements in design, which have made it possible to greatly decrease the distance between wheels and also

to generate higher voltage, viz., 12,200 instead of 4600. The tremendous capacity in a single turbine barrel and in a single generator is given by the size of the exhaust opening, which is rectangular and measures 12 by 18 ft. in the clear. The unit is supplied with steam through two lines, each 14 in. in diameter, and the steam from the exhaust passes directly downward through a short expanding neck into the condenser, which, like the turbine, is the largest yet attempted in a single shell. It is also unique among condensers of this general class in that it is arranged for but one water pass. The circulating

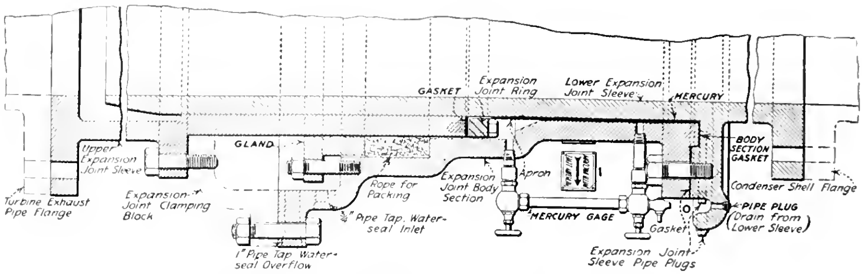

FIG. 10 DETAILS OF THE MERCURY EXPANSION JOINT FOR CONDENSERS

water enters all the tubes at one end and leaves all at the other end, flowing away over a dam, the crest of which is so located as to submerge the highest tubes.

In order to prevent an excessive cooling of the condensate, special devices called drain plates were installed. These drain plates are formed by placing light-weight metal plates in the steam space in such positions as to catch the condensate from the upper sections and lead it to the bottom of the condenser without allowing it to come in contact with the tubes in the sections through which it is led. These plates are not intended as steam guides or baffles, and their successful use depends on placing them in such positions that they do not interfere in any manner with the free flow of steam. (*Power*, vol. 57, no. 8, February 19, 1918, pp. 255-256, *d*)

STEAM-RAISING BY ELECTRICITY, WITH HEAT STORAGE, E. Höhn (*Schweiz. Bauzeitung*, 69., April 28, 1917. *Elektrot. u. Maschinenbau*, 35, pp. 316-317, July 1, 1917. Abstract). Describes tests made in October, 1916, by the Swiss Union of Boiler Owners, on a boiler in which steam was raised electrically. A horizontal cylindrical boiler with flat ends had 28 steel tubes of 27 and 28 mm. diam. and 1250 mm. free length. The effective heating surface in contact with water was 4.25 sq. m. (34 tubes), the permissible steam pressure 2.5 atmos. Each of the 34 active tubes contained a spiral nichrome wire threaded through glass beads and about 54 m. long, 0.9 mm. diam. and with a specific resistance of 1 to 1.1 ohms. For convenience in control, the heating spirals were arranged in groups of 18, 9 and 7. Approximately the current consumption was 115 amp. at 225 volts. The evaporation in two tests was 12.8 and 13.5 kg. per hr. per sq. m. heating surface, and 1.212-1.205 kg. per kw.-hr., respectively. The thermal efficiency of the boiler is 89.8-90.5 per cent.

In order to work economically, plenty of cheap electrical energy is needed; this may be secured by applying waste power to steam raising and storing heat on the principle of the fireless locomotive. The author discusses the economy of such an installation in which 100 hp. of waste power is converted to heat during 12 hours and stored in this form. As regards the size of storage necessary: If E = available energy in kw-hr., A = heat equivalent = 859 kg-cal. per kw-hr., and η = efficiency of evaporation; then heat W transferred to steam = ηEA, and if t = feedwater temperature and i = heat content of saturated steam, we have weight of steam = G kg. = $\eta EA/(i - t)$. Further, let Q be the number of kg. of water in reservoir before discharge, D the weight in kg. of steam evaporated from the accumulator during discharge, t_3 = the temperature of the feedwater, w_3 = its heat content ($= t_3$), t_2 the temperature of water and saturated steam in accumulator at pressure p_2 after discharge, w_2 and i_2 the heat contents of water and steam, respectively, t_1 the temperature of water and saturated steam at pressure p_1, after charging, and w_1, i_1 the heat contents of water and steam. Then the heat remaining in the accumulator after discharge = $Q - D$. The charging heat = $EA\eta = Q(w_1 - w_2) + D(w_2 - w_3)$. The amount of Q which can be "self-evaporated" as steam is $D = Q(w_1 - w_2)/(i_m - w_2)$. Hence $Q = EA\eta/[w_1 - w_2 + x(w_2 - w_3)]$. Knowing the weight of water, Q, the volume is easily calculated.

Applying these equations to the above numerical example, we have the heating surface = 7.5 m.^{2} corresponding to a boiler 800 mm. in diam., 1600 mm. between tube plates, with 47 tubes of 27/32 mm. diam. The accumulator water content Q = 9370 kg. and the total accumulator volume V = 11.8 m.^{3}, corresponding to a cylindrical vessel of 1.5 m. internal diam. and 6 m. high. The weight of steam removable from the accumulator is D = 1020 kg. The efficiency of the accumulator is 94-95 per cent, and of the whole installation, including boiler, 82 per cent. Of the electrically generated steam G = 1020 kg., 960 kg. can be recovered from the accumulator, corresponding to a coal economy of about 130 kg. per day. This covers interest and depreciation and leaves a small margin for current cost. If there is no direct charge for current supply, the plant may be used even to accumulate heat on Sunday for use during the rest of the week. Neither boiler nor accumulator requires any appreciable attendance. (*Science Abstracts, Section B—Electrical Engineering*, No. 24, December 31, 1917, pp. 435-436)

Thermodynamics

THE GAS-FILM THEORY IN RELATION TO HEAT CONDUCTION, Halbert T. Gillette, Mem.Am.Soc.M.E. The writer starts by citing a statement by Prof. H. L. Callendar on the adherence of gas films to solids, and the paper by Irving Langmuir (1912), where he showed that the film of quiescent air adhering to incandescent wires is 0.17 in. thick. This led the present writer to make some experiments with the view to determining the film thickness of water.

He found that at low temperatures and in water not mechanically stirred, the equivalent film thickness of water is about 0.05 in.

Next the writer undertook to determine the equivalent film thickness of steam. In this respect he has not yet secured sufficient experimental data to deduce a formula for all conditions, but claims to have established the fact that the equivalent film thickness of steam is far less than that of air, which, if correct, is of material importance.

In its simplest form, the film theory of the writer is graphically illustrated in Fig. 11. There a temperature gradient is shown from t_1 to t_4 through two gas or liquid films and a solid. This figure represents heat conduction from a gas or liquid through a solid to a gas or liquid. Heat flows from a temperature t_1 through a film of thickness d_1 to a solid, which it enters at a temperature t_2, dropping to t_3 and thence to a temperature d_3. While the actual heat gradients through gases or liquids

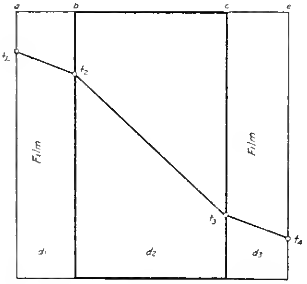

Fig. 11 Diagrammatic Illustration of the Film Theory

are not straight lines, for simplicity's sake each film is here assumed to conduct heat exactly as if it were a solid. This may be legitimized by the use of the term "equivalent film thicknesses." If by H we denote the number of heat units that pass through this system in one hour, by k_1, k_2 and k_3 the coefficients of heat conductivities of the respective films, the equation

$$d_1 = k_1 \frac{t_1 - t_2}{H}$$

will give the equivalent film thickness when the other factors are known. Usually t_2 is not known directly, but if we know H, d_2 and k_2, we may calculate $t_2 - t_3$ from the equation

$$t_2 - t_3 = \frac{Hd_2}{k_2}$$

and from this we can readily deduce t_2, or if the films are of the same gas or liquid, the drop in each film. Also, t_3 can often be measured.

The writer calculates the amount of heat which will pass through a glass window from a room whose temperature is 70 deg. fahr. to quiescent air outside at a temperature of 50 deg. fahr., assuming that the plate of glass is 1 ft. sq. and 1/8 in. thick. This calculation is based on a table reproduced in the original article and giving coefficients of heat conductivity for a large number of solids, liquids and gases. The author shows that while the total temperature drop is 20 deg., only 0.2 deg. is the share of the drop through the glass, while 19.8 deg. is the drop through the two air films, which clearly shows the extent of resistance to heat transfer offered by the air films as compared with glass an eighth of an inch thick. This result was secured, however, only by ignoring the heat lost by radiation from the surface of the glass.

Further, the influence of the air film decreases rapidly when the air is mechanically agitated, as when the wind is blowing or powerful convection currents take place. This is one of the reasons why double windows or double glazing is so effective in reducing heat losses. In a double window there are four air films instead of two, and a strong wind can reduce the thickness of only one of the four.

In his analysis of available experimental data on heat transfer, the author was struck with the slight resistance offered by steam. By deduction he secured for steam a coefficient of conductivity not greatly differing from that for air at the same temperature, but found that steam transfers heat many times faster than does air, which, in his opinion, is possibly only because the equivalent film thickness of steam is much less than that of air. Water in the ashpit of a boiler has long been known to increase fuel efficiency under certain conditions. The author believes that the reason for it is that the steam film facilitates the transfer of heat through the boiler tubes to the water and steam film on the other side.

Brief indications are given as to the method of applying the film theory as exposed here to the design of windows and heat-insulated walls. In particular, as to the latter, the writer designed a heat insulator in which the walls are hermetically sealed, and the space between filled with granular or fibrous material and a gas of low conductivity, such as CO_2 or SO_2. Such a gas-filled insulator has more than double the heat resistance of an ordinary air-film insulator of equal thickness. (*Engineering and Contracting*, vol. 47, no. 26, June 27, 1917, pp. 573-576, *etA*.)

Thermodynamics of the Throttle Valve, M. Jakob. (*Phys. Zeits.* 18., pp. 421-422, Sept. 15, 1917.) This paper is a discussion of a previous communication by R. Planck [see Abs. 146 (1917)]. From his formula [1], namely:

$$v/T = c^0_p\, 10^4 \cdot A \cdot \int 1/T^2\, (\partial A/\partial p)\, r dT + f\,(p)$$

Planck derived the following equation of state [2] for the air:

$$v = RT/10^4 \cdot p - 0.0103\,(8.9/T^{-7868}/T^2 + 15p^2/T^6)$$

and then deduced an expression [3] for the cooling produced during reduction to atmospheric pressure by the throttle valve:

$$\triangle = -17.8_p/T + {}^{250}p/T^2 - {}^{20}p^3/T^7.$$

Schames has shown [*ibid.* p. 30, 1917] Equation [2] to give false values for the volumes, and Planck's reply to his criticism [Abs. 314 (1917)] was that his empirical equations only held in the region of — 100 deg. to 0 deg. cent., and from 70 deg. to 200 deg.; even within this zone, however, v deviates too strongly from observation values and at the higher pressures by over 10 per cent. Schames has not supplied the cause of this variation in Equation [1], and in the present paper this is shown to be essentially due to the assumption made by Planck for $f(p)$. In order to modify formula [1] so as to hold between wide limits, Equation [3] must be suitably replaced by one of greater validity. Planck's assumption that $f\,(p) = R/10^4 p$, is found to be only correct when the conditions are those for a perfect gas. The author evolves a value for $f(p)$ which gives results correct in practice to 1 per cent. Schames's criticism is also met by a suitable modification of Equation [3]. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 1, no. 241, January 31, 1918, pp. 26-27. The formulæ [1], [2] and [3] above are given as printed in *Science Abstracts*.—Editor.)

The Nernst Theorem and the Thermal Expansion of Solid Bodies, M. B. Weinstein. (*Ann. d. Physik*, 53, 9. pp.

47-48, October 2, 1917). In a former communication [Abs. 520 (1917)] the author has shown that on the Planck view of Nernst's theorem it does not of necessity follow that the thermal expansion of bodies, for which the theorem is valid, is nil at the absolute zero of temperature. In the present paper the author proceeds to deduce the same result from Nernst's exposition of his own theorem. The author refers to his own work on the equation of state for solid bodies, where a similar result is found for many substances. Reasons are given why Nernst's statement of his own theorem is considered preferable of that of Planck. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 1, no. 241, January 31, 1918, p. 23)

On the Nernst Theory of Heat, P. S. Epstein. (*Ann. d. Physik*, 53, pp. 76-78, October 2, 1917). Weinstein has recently [Abs. 520 (1917)] investigated Planck's explanation of Nernst's theory of heat. This he has modified to the extent of finding that the entropy of a condensed body at absolute zero is not an absolute constant but may be dependent on the pressure. The present author now puts forward a thermodynamical exposition of this proposition, and this points to Weinstein's assumption being incompatible with the second law of thermodynamics. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 1, No. 241, January 31, 1918, p. 23)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

The city of Philadelphia has awarded the John Scott Legacy Medal and Premium to Max Ulrich Schoop, of Zurich, Switzerland, for the Schoop Metal Spraying Process. In this process, wire of some easily fusible metal, like zinc, is fed into a device called a spraying pistol. The wire passes through a tube, and at its end comes into contact with burning gas, by which it is melted, and the molten metal is sprayed by an air blast upon the surface to be covered. The use of this process has been found to greatly increase the life of patterns for castings.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

WAR LIBRARY SERVICE

GOOD books are urgently needed for our soldiers and sailors here at home in the training camps, on transports, in the Navy and overseas in the trenches.

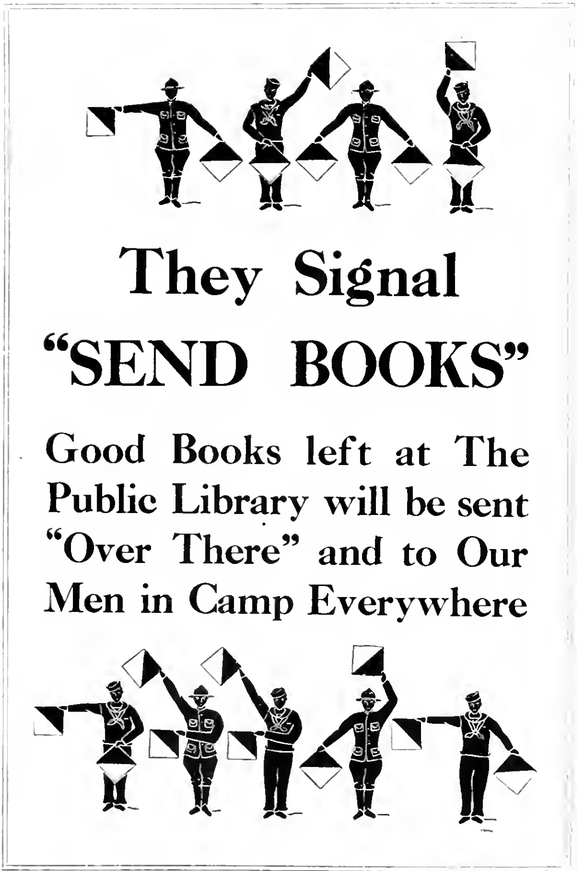
A fund of $1,700,000 has been raised by the American Library Association to build and equip thirty-four libraries in the camps, to provide trained library service, and to buy books. The service includes all Y. M. C. A., K. of C. and Y. M. H. A. huts, hospitals, Y. W. C. A. hostess houses, and many other distributing agencies. The work has grown wonderfully, and to supply the unexpectedly great demand for books and thriftily save the fund, the American Library Association calls for gifts of books from the public.

Every camp librarian reports a steady, large demand for technical works of every class. The war is an engineers' war, and the need for engineering data is acute. The American Library Association intends to devote its funds as far as possible to the purchase of scientific and technical books and other works of a serious nature, but it will appreciate greatly any gifts of this kind, as well as of recreational reading.

Over 600,000 books are now in use, but hundreds of thousands more are needed. Multitudes of good books that would be of the greatest service are standing unused on shelves in our homes. Others that are treasured would be given gladly if the great need were known. Many useful engineering works stand on office shelves, not in actual use and rapidly growing obsolete. Their presentation to the Army would be a real service. Obviously, the technical books sent should be recent editions.

To present books, all that is necessary is to mark them "War Library Service" and deliver them at any public library. They will be forwarded to the war-library storage plant and distributed to the points where they are most needed.

HARRISON W. CRAVER.



BOOK REVIEWS

The Taylor System in Franklin Management: Application and Results. By Major George D. Babcock, in collaboration with Reginald Trautschold, with a foreword by Carl G. Barth The Engineering Magazine Co., New York, 1917. Cloth, 5½x8½ in., 265 pp., 26 figs., including 4 folding charts. $3.

Aside from the real merit which this book possesses as an exposition of scientific management, it is very interesting because it gives a fairly full account of the introduction and building up of one of the best-known successful installations of the Taylor methods, namely, in the plant of the H. H. Franklin Manufacturing Company. Considerable of the subject-matter was published originally in *Industrial Management*, but it has, of course, been edited and supplemented for this volume.

The first two chapters are devoted to the conditions in the Franklin plant in 1908 prior to the introduction of the new system and to the investigation and reasoning that led to the installation of scientific management, so-called. Chapters III, IV and V treat of the methods by which the product was classified and the methods by which the flow of product was controlled. The complex-appearing control board invented by Major Babcock is described fully, as well as other features of the control and dispatching system.

Chapter VI discusses employment and rate fixing. Chapter VII describes the Franklin organization, while Chapter VIII discusses how changes in product and method are handled.

Chapter IX, entitled Changes That Have Affected the Men, is most interesting in that the author concludes that the Taylor system as operating at the Franklin plant is far from a mechanical system, so far as men and women are concerned, as is usually supposed. On the other hand, he claims that it is distinctly human and brings out the best there is in all workers. The concluding chapter shows how the results of the plant operations are depicted graphically.

In addition to these chapters there are two appendices. The first, entitled Wage Rates in the Franklin Shops, gives some specific experiences with the wage system discussed in the chapter on employment and rate setting. The second appendix is devoted to suggestions concerning the best form of scientific management for repair shops, small-part factories and plants with uniform manufacture.

One of the most interesting chapters is that on employment and rate fixing. It describes an interesting though complex attempt to fix the worker's compensation by taking account of all the variables such as the percentage of increase in cost of living. Like all such efforts it rests upon the prevailing wage rates, and the author very sagely points out that no successful attempt has as yet been made to fix an accurate base rate. The important feature of the chapter, however, is the attempt on the part of the management to do what was fair. Perhaps this attempt had considerable to do with the success of the whole plan.

The book is filled with useful information for those who wish to study these new methods. It is true that the conditions of manufacture in the Franklin shops lend themselves more readily to the Taylor system than do many others, but all manufacturers and students of efficiency can read this book with profit.

Dexter S. Kimball.

The Taylor System of Scientific Management. By C. Bertrand Thompson. A. W. Shaw Co., New York, Chicago and London, 1917. Flexible cloth, 9x11 in., 175 pp., 43 illustrations and 22 forms, charts and diagrams. $10.

Mr. Thompson's book, as its name implies, is a report, or rather a review, of the Taylor system of management, with an account of some of the results that have been accomplished and a discussion of methods to be pursued in securing results with this system. His findings are based upon his own long and intimate experience with scientific management, supplemented by a personal investigation, covering a large part of four years, of nearly all the installations of the Taylor system in this country prior to 1915.

Considerable of the subject-matter has appeared in the magazines *System* and *Factory*, and in The Library of Factory Management. All of this matter has been thoroughly edited and revised. The aim of the author has been to make clear the differences between the Taylor system of management and other systems, and to present in a clear manner the general principles and most important mechanisms of the Taylor system as found in actual practice. It would appear that he has succeeded admirably in accomplishing his purpose. The book is tastefully illustrated and liberally provided with marginal notes that are helpful in grasping the most important parts of the discussion. It is bound in manual form, and provision is made for comments and memoranda by the reader.

The discussion is non-technical in character, and is written in a simple, readable manner, the aim being apparently to present the Taylor system clearly to those who know little about it, and to managers who may be desirous of finding out more concerning it with a view of installing efficiency methods. It is suited, therefore, to elementary students of efficiency methods, factory managers, and superintendents and general readers who are curious concerning the Taylor system, but who have neither the patience nor preparation to read Mr. Taylor's original writings.

The book is naturally somewhat biased in favor of the Taylor methods, and, like many books on this or other modern efficiency systems, it is liable to give the impression that all that is good in modern management came in with these modern methods. It hardly makes clear that many of the ideas and mechanisms employed by Mr. Taylor and his contemporaries in this work were in actual use before they launched their crusade.

However, Mr. Thompson makes some very convincing arguments, and his statements concerning the number of installations that have been successful, and his analysis of the reasons why some of them have failed, are well worth considering. Aside from this, also, the book will be interesting reading to those who are well informed on these matters, as it is the statement of one who has had long and intimate connection with the Taylor methods.

Dexter S. Kimball.

Applied Motion Study. A Collection of Papers on the Efficient Method To Industrial Preparedness. By Frank B. Gilbreth, Mem.Am.Soc.-M.E., and Lillian M. Gilbreth, Ph.D. Sturgis & Walton Co., New York, 1917. Cloth, 5x7½ in., 220 pp., 17 illustrations and 1 folding chart. $1.50 net.

This book, as its subtitle implies, is a collection of papers presented by the authors before different scientific societies or printed in the Annals of the American Academy of Political and Social Science. The titles of the several papers are: 1. What Scientific Management Means to America's Industrial Position. 2. Units, Methods and Devices of Measurement Under Scientific Management. 3. Motion Study as an Industrial Opportunity. 4. Motion-Study and Time-Study Instruments of Precision. 5. Chronocyclegraph Motion Devices for Measuring Achievement. 6. Motion Models: Their Use in the Transference of Experience. 7. Motion Study for the Crippled Soldier. 8. The Practice of Scientific Management. 9. The Three-Position Plan of Promotion. 10. The Effect of Motion Study upon the Workers.

Mr. (now Major) Gilbreth is the father of modern motion study. He began it on July 12, 1885, when he studied the motions of two expert bricklayers who undertook to teach him their trade. He has been studying motions ever since, and now holds a commission as Major in the U. S. Army, with the special duty of utilizing motion study in the training of crippled soldiers for productive work and in modifying and adapting the work to the capabilities of the cripple. We quote the following from an introduction by Mr. George Iles:

> This is a book written from the heart as well as from the brain. Its good will is as evident as its good sense. Frank B. Gilbreth is a versatile engineer, an untiring observer, an ingenious inventor, an economist to the tips of his fingers: first and chiefly he is a man. To his wife, co-author with him, this book owes much. Every page has taken form with the aid and counsel of Mrs. Gilbreth, whose Psychology of Management is a golden gift to industrial philosophy. And thus, by viewing their facts from two distinct angles we learn how vital phases of industrial economy present themselves to a man and a woman who are among the acutest investigators of our time.

The greater part of the book is devoted to descriptions, in popular style, of the several inventions that have facilitated motion study. The following, in the words of the authors, is a brief outline of these descriptions:

> Scientific management is simply management that is based upon actual measurement.
>
> Motion study, time study, micromotion study, fatigue study and cost study are important measures of scientific management.
>
> Micromotion study consists of recording the speed simultaneously with a two- or three-dimensional path of motion by the aid of cinematograph pictures of a worker and a clock that shows divisions of time so minute as to indicate a different time of day in each picture in the cinematograph film.
>
> Motion study consists of dividing work into the most funda-

mental units possible; showing these elements separately and in relation to one another, and from these studied elements when timed, building methods of least waste.

The chronocyclegraph method of making motion study consists of fastening electric-light bulbs to the fingers, or to any part of the operator or of the material whose motion path it is desired to study. If the direction, relative time and relative speed are to be noted, the path of light, through controlled interruptions of the current, is made to consist of dots or dashes, or a combination of the two, with angle-pointed ends, the point showing the direction. Through the micromotion studies and the chronocyclegraph studies the expert formulates the standard method.

By taking the photograph stereoscopically we were able to see this path in three dimensions, and to obtain what we have called the stereocyclegraph. The time element is obtained by putting an interrupter in the light circuit that causes the light to flash at a known number of times per second. This gives a line of time spots in the picture instead of a continuous cyclegraph light line. Counting the light spots tells the time consumed.

The next step was . . . to find the right combination of volts and amperes for the light circuit and the thickness of filament for the lamp to cause quick lighting and slow extinguishing of the lamp. This right combination makes the light spots pointed on their latest, or forward, ends.

The points, thus, like the usual symbol of arrow heads, show the direction. The result was then, of course, stereochronocyclegraphs showing direction.

Wire models of cyclegraphs and chronocyclegraphs of the paths and the times of motions are now constructed that have a practical educational value besides their importance as scientific records.

We have a double cinematograph, that one part may record while the other moves from one exposure to the next.

For such cases [where there is an objection to the presence of an observer] we have designed an automicromotion study which consists of an instantaneous modification of the standard micromotion apparatus, and also the autostereochronocyclegraph apparatus. This enables the operator to take accurate time study of himself.

Through a method of using the same motion-picture film over and over again up to sixteen times . . . we have been enabled to cut down the cost of making time and motion study, until now the most accurate type of studies, involving no human equation in the record, can be made at less cost than the far less accurate stop-watch study.

The penetrating screen makes it easier to visualize and to measure the elements of the cycle being studied. A cross-sectioned screen of known dimensions can be introduced at any place where it will enable one to secure a more accurate record of the motion.

The data ascertained by these motion devices are placed on the simultaneous motion cycle chart. This analyzes a motion cycle into its component parts, and indicates graphically by which member of the body, and in what method, each portion of the cycle is performed. By the comparison of the analyzed motion model with the data on the chart, the possibility of the transfer of work from one working member of the body to another is indicated. The simultaneous motion cycle chart....has been presented by the writers for the benefit of the crippled soldiers in whose interests they are at present engaged.

We heartily commend this book to the attention of all those who are interested in the latest developments in scientific management, and especially in that branch of it that relates to the elimination of waste motion. The book, being merely a collection of papers and addresses, lacks, of course, the unity and systematic method of a logical and scientific treatise, such as it is to be hoped the Gilbreths may publish after the war is over, when they may find the time for its preparation.

A "final note," at the end of the book, informs us that the authors requested that it be printed in accordance with the forms of spelling recommended by the Simplified Spelling Board, but the publishers ruled otherwise. We congratulate the publishers upon their ruling. The authors are geniuses, of course, and must be allowed to have some of the eccentricities of genius, but they should not be allowed to give offense to their readers by flinging reformed spelling at them. If they wish to save ink and paper they can save a hundredth of one per cent by reformed spelling, but they can save a thousand times as much by blue-penciling their manuscript and cutting out ten per cent of it, and the "boiling down" would improve its quality.

William Kent.

The American Year Book: A Record of Events and Progress for 1917. Edited by Francis G. Wickware, B.A., B.Sc., with the cooperation of a supervisory board representing national learned societies. D. Appleton & Co., New York and London, 1918. Cloth, 5x7¾ in., xx+822 pp. $3 net.

In the present edition of this important and comprehensive digest, that which has been accomplished during the past year in the great departments of learning and human activity—history, politics, government, legislation, foreign relations, industry, science, engineering, the arts, the professions, literature, etc.—has been tersely reported by the members of a board consisting of over 100 accredited representatives or members of some forty American learned and scientific societies. The 31 sections of the work include articles on hundreds of topics, many of them relating to the war, ready reference to which is afforded by an extensive index containing nearly 6000 items. Section XXII, devoted to engineering, comprises 34 pages, eleven of which deal with progress in the field of mechanical engineering, and were contributed by Messrs. Calvin W. Rice, Secretary of the A.S.M.E., and Leon Cammen, associate editor of The Journal.

LIBRARY ACCESSIONS

Activated Sludge Process of Sewage Treatment. A bibliography of the subject. By J. Edward Porter. *Rochester, 1917.* Gift of General Filtration Company.

The Aldrich Marine Directory, Containing (A) List of Concerns which Build and Repair Vessels, (B) List of Steamship, Steamboat and other Vessel Owners Using the American Flag. Aldrich Publishing Co., *New York, 1918.* Flexible cloth, 8 x 4 in., 220 pp. $5. Gift of the publisher.

Automobile Starting, Lighting and Ignition. By Victor W. Pagé. A Complete Exposition Explaining all Forms of Electrical Ignition Systems Used with Internal Combustion Engines of all Types, also Including a Comprehensive Series of Instructions Pertaining to Starting and Lighting Systems of Automobiles. 4th ed., revised. The Norman W. Henley Publishing Co., *New York, 1918.* Flexible cloth, 5 x 8 in., 519 pp., 298 illus., $1.50. Gift of the publisher.

Aviation Engines. By Victor W. Pagé. Design, Construction, Operation and Repair. A Complete, Practical Treatise Outlining Clearly the Elements of Internal Combustion Engineering with Special Reference to the Design, Construction, Operation and Repair of Airplane Power Plants; also the Auxiliary Engine Systems, such as Lubrication, Carburetion, Ignition and Cooling. It Includes Complete Instructions for Engine Repairing and Systematic Location of Troubles, Tool Equipment and Use of Tools, also Outlines the Latest Mechanical Processes. The Norman W. Henley Publishing Co., *New York, 1918.* Cloth, 6 x 9 in., 589 pp., 253 illus., $3. Gift of the publisher.

Aviation Pocket Book for 1917. By R. Borlas Matthews. *London, 1917.* Purchase.

Axial Aberrations of Lenses. (U. S. Bureau of Standards. Scientific Papers, no. 311.) *Washington, 1917.* Purchase.

Central Stations. By Terrell Croft. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6 x 8 in., 332 pp., 306 illus., $2.50. Gift of the publisher.

COLORADO. Mining map showing the distribution of the main geological periods from the Archean to the Tertiary with the occurrence of the various metals therein and some of the non-metals, as oil, coal, etc., compiled by R. L. Chase. Gift of Bradley Stoughton.

COMPARATIVE TESTS OF PORCELAIN LABORATORY WARE. (U. S. Bureau of Standards. Technologic Papers, no. 105.) *Washington, 1917.* Purchase.

CONTINUOUS CURRENT MOTORS AND CONTROL APPARATUS. By W. Perren Maycock. A Practical Book for all Classes of Technical Readers. Whittaker & Co., *New York, 1917.* Cloth, 8 x 5 in., 331 pp., 150 illus., $2.25. Gift of the Macmillan Co.

CORRECTION TABLES FOR THERMODYNAMIC EFFICIENCY. Calculated by C. H. Naylor. *London, 1917.* Purchase.

CREOSOTED WOOD STAVE PIPE AND ITS EFFECT UPON WATER FOR DOMESTIC AND IRRIGATION USES. (University of Washington, Bureau of Industrial Research. Bulletin No. 1.) *Seattle, 1917.* Gift of University of Washington.

SPRING MEETING PAPERS

IN A RECENT ADDRESS, Past-President Hollis, who will be one of the Society's hosts at the coming Spring Meeting, expressed the relation of the engineer to the war in the following words: "We all know that this war is a problem in manufacture, business and organization. Much of it is engineering, but it is not an engineer's war, a farmer's war nor a banker's war. It is a people's war in which every individual, man, woman and child, counts for something."

While it is true that the burden falls heavily upon those whose business it is to secure mass production of the mechanical devices required by our men at the front, the first responsibility of the engineer is that of a loyal citizen, ready to answer the call for public service. It is in this spirit that the members of the Society are counseled to meet at Worcester, Mass., June 4 to 7, for conference, mutual help and inspiration. It will be a time for interchange of ideas, planning for the future and a strengthening of one's abilities so that each may return to his strenuous duties better equipped for the months which are to follow. This will be the third war convention of the Society, with a remarkable program carefully developed in all its details, and having a direct bearing on the stupendous undertakings in which the members of the Society are engaged.

Readers of THE JOURNAL are referred to page 404 of this issue for the program of the meeting, and other information of interest to those expecting to attend.

PAPERS FOR GENERAL SESSIONS

THE SPRING MEETING PROGRAM comprises a number of addresses, papers and discussions relating to the procurement and manufacture of supplies for the Government, ways and means for effecting fuel economy, and the problem of instructing and housing labor under war conditions; besides the usual number of general technical papers necessary to maintain the TRANSACTIONS of the Society. These general papers are published in abstract form in this number of THE JOURNAL, discussion upon which is solicited. Other papers contributed by the New England Sections and the Providence Engineering Society will appear in the next number. Except in a few instances, the matter relating to the war will be in the form of addresses or topical discussions, and will be published after the meeting. Pamphlet copies of the complete papers will be ready for distribution to all who desire them in advance of the meeting.

EFFECT OF MOISTURE REABSORPTION ON COMPRESSIVE STRENGTH OF AIR-DRIED TIMBER

BY IRVING H. COWDREY,[1] CAMBRIDGE, MASS.

Non-Member

THE effect of moisture on the properties of timber has become a well-established and recognized fact. Every practical man, whether he be an engineer or a craftsman, knows full well that the removal of moisture from timber, or the so-called "seasoning," produces marked changes in its strength, hardness, stiffness, resiliency and other characteristic properties. Much has been done in the way of scientific investigation by the Bureau of Forestry, The Forest Products Laboratory and various universities and technical schools to determine the effect of the progressive removal of moisture on the strength of timber of all kinds, and the results obtained have been published.

To the reversal of this process there has been given considerably less attention. There is often expressed great surprise at the rapid and very appreciable regain of moisture by wood after it is removed from the dry kiln. This reabsorption, moreover, is not confined to kiln-dried wood, but occurs as well in the case of timber which has been thoroughly air-dried. In fact, the reabsorptive power of air-dried timber is believed to be somewhat greater than is that of timber which has been properly and thoroughly kiln-dried. The effect of atmospheric conditions on the physical properties of timber through their effect on the moisture content of the wood is well exemplified by the behavior of certain beams which were subjected to a time test under load for several years in the laboratories of the Massachusetts Institute of Technology. During the summer months these beams always manifested a very noticeable stiffening and consequent decrease in deflection at the center, even though subjected to load far in excess of the proper working load for such beams. While, of course, no moisture determinations were possible under the conditions noted above, yet the common fund of engineering knowledge would point to the moisture factor as the proper explanation of this observed behavior.

PROBLEMS TO BE SOLVED

If, then, wood responds so quickly in its reabsorption of moisture under very ordinary atmospheric conditions, and in consequence thereof undergoes change of properties, how much greater will be the response and the consequent change of properties if the timber be introduced into a saturated atmosphere at reasonably high temperatures, or if it be completely submerged in water? For example, if the roof of a laundry or of the dye house or finishing room in certain textile industries be of a timber-truss or beam construction, what is the effect on such timbers of the temperature of, say, 120 deg. fahr. with saturation? Again, suppose the basement of a heavily loaded warehouse be flooded. If the supporting col-

[1] Department of Mechanical Engineering, Massachusetts Institute of Technology.

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

mns be of timber, to what extent will their ability to reabsorb moisture affect the stability of the structure?

A recognition of the importance of these items and the belief that reabsorption is a factor to be reckoned with has led to the conducting of a series of investigations during the past year in the Testing Materials Laboratory of the Massachusetts Institute of Technology to determine the quantitative effect, if possible, of such conditions.

During the past few years the eastern lumber markets, as typified by Boston, have witnessed the entrance of Douglas fir (*Pseudotsuga Douglasii*) as a competitor in the field of structural timber. This fact led the experimenters to make a parallel investigation for purposes of comparing this timber with the better-known southern hard pine, which has been so long established in the structural engineering of New England. In so far as the writer is aware, this is the first work of the kind to have been done on Douglas fir. The pine used

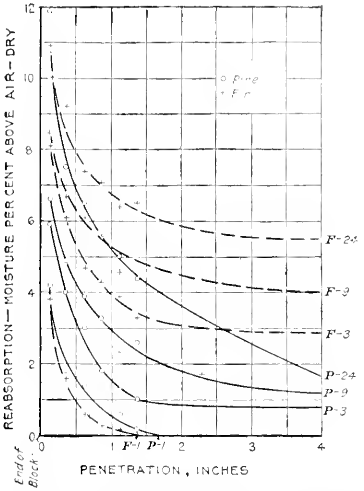

FIG. 1 REABSORPTION OF SPECIMENS WHEN EXPOSED TO SATURATED AIR AT 120 DEG. FAHR.

P-1 indicates pine treated 1 hr.; *F-9*, fir treated 9 hr.; other symbols to be similarly interpreted.

falls under the classification of "dense southern pine" according to the standards of the American Society for Testing Materials, and is very probably the long-leaf yellow pine (*Pinus palustris*).

The tests were carried out, it is true, upon small specimens, and in consequence are open to criticism such as has been made concerning much of the work which has been done by the Bureau of Forestry. It must be acknowledged that the results are scarcely to be used as constants of design, but it is believed that they may well be used as indicative of certain truths and as a means of comparison in the guidance of the users of the two timbers placed under observation.

NATURE OF THE INVESTIGATION

The investigation under discussion may be briefly outlined as follows: The stock used had been purchased in the open market without any special care in selection. In the form of 4-in. planks it remained in the testing laboratories about six months under the conditions of heat and moisture ordinarily pertaining to such localities, being open to free and complete circulation of air over and around the material.

Tests showed the moisture content to be between 6 and 8 per cent for all pieces. The timber, then, may be considered to have been thoroughly air-dried. From these planks were cut specimens which were planed to a section 2 in. by 2 in. and 20 in. long. These pieces were cut further into blocks 8 in. long, and the pairs thus obtained were used in most cases under similar conditions of treatment for check purposes. All treatments were conducted on specimens 8 in. long and tests were made on specimens 6 in. long formed by the removal of 1 in. from each end of the treated specimen.

A number of specimens of both pine and fir were tested in the air-dry condition to establish their initial properties. One set consisting of 20 pieces of pine and 20 pieces of fir was subjected for various lengths of time to a saturated atmosphere at 120 deg. fahr. Another similar set was immersed in fresh water at 70 deg. fahr. for various periods of time.

While the moisture even in so thin a block as those investigated will doubtless vary from surface to surface, yet it seems sufficiently accurate for the purposes of this paper to take the average value as representative of the conditions at the center of the section. These values have been so assumed and are plotted in the curves of Figs. 1 and 2.

The water present in wood may exist (*a*) as free water within the cellular spaces, the canals and ducts, and possibly to some slight extent in the intercellular cavities; and (*b*) as water which has been actually absorbed by the material which constitutes the cell walls.

It is commonly supposed that the absorption of water from moist air at least is first an absorption by the cell walls, and that later under some conditions there occurs a partial filling of the cell cavities. The maximum water content possible without the presence of free water in the cells and canals is known as the "fiber-saturation point." When water is absorbed because of the actual immersion of the wood it is very likely that free water may exist in the cells without the cell walls having absorbed a quantity sufficient to produce fiber saturation. For most of the commoner timbers this fiber-saturation point occurs at a moisture content of approximately 25 per cent.

Most writers consider that it is only this second form, or "imbibed" water, as it is sometimes called, which affects the strength. No satisfactory theories have been advanced to elucidate the phenomenon. It would seem to the writer as though perhaps there may occur some of the effects of colloidal solution, which may to some extent be borne out by the fact that a very complete kiln-drying at high temperature prevents or markedly decreases certain effects commonly produced by reabsorption of moisture such as swelling, increase of pliability, etc.

Again, the writer would hold that the free water in the cells and canals may also have a weakening effect, due to re-solution of some of the salts which are undoubtedly deposited within the cells as the sap dries out, or in the case of heart wood by infiltration during the life of the tree. These crystalline deposits, it would seem, must have a stiffening effect, and, if present in sufficient quantity to fill completely the cell or to bridge it at any point, should add quite materially to the rigidity of the cell, as latticing adds to the rigidity of structural compression members.

RELATIVE RATES OF MOISTURE PENETRATION LONGITUDINALLY

Only the rate of penetration in the direction of the fiber was investigated. The specimens, in the form of blocks 2 in. by 2

in. by 8 in. were subjected to the desired treatment for periods ranging from one hour to 117 hours. At the end of the period of treatment the moisture content was obtained as previously described.

Reabsorption When Exposed to Saturated Air at 120 Deg. Fahr. The specimens were treated by placing them on a grid just above the surface of hot water in a covered steamer freely vented to the air. The temperature of the vapor in the steamer was maintained within the limits of 2 deg. fahr. variation during the longest period of treatment, namely 24 hours.

Fig. 1 shows the reabsorption of the specimens during periods of 1, 3, 9 and 24 hours of treatment. It has seemed best to plot the reabsorption in terms of the moisture content in excess of that present in the air-dried condition rather than the absolute moisture content. This was done to eliminate if possible any variation of hygroscopic action inherent in the specimen due to structural peculiarities.

Referring to curves *P*-1 and *F*-1 representing the conditions at the end of an hour's treatment, it will be noticed that no reabsorption was manifest beyond a point approximately 1½ in. from the end. The curves *F*-3 and *P*-3, showing the effect of 3 hours' treatment, clearly indicate some absorption, even at a distance of 4 in. from the exposed end grain. This furnishes a very striking example of the extreme rapidity with which moisture will penetrate along the grain of timber when it is exposed to the action of hot, moist air.

It should be noted that in none of the treatments did the reabsorption become greater than 12 per cent average moisture in the first ¼ in. from the end. With the air-dry condition of 8 per cent of moisture or less, giving total moisture 20 per cent or less, it would seem that the fiber-saturation point was not attained. However, the point plotted represents the average only for the first ¼ in., and as the plots show, the moisture content decreases very rapidly at first; hence it seems fair to presume that the walls of the cells immediately adjacent to the surface may have reached the point of saturation. From this it might be inferred that saturated air at 120 deg. fahr. is capable of producing fiber saturation. It seems also reasonable to suppose that if the treatment were continued for a period of sufficient length this condition might extend throughout the timber regardless of size. The logical conclusion to be drawn from this leads to the statement that *timbers subjected to the action of saturated air at 120 deg. fahr. must be designed on a basis of constants determined from tests on green timber.*

Reabsorption When Completely Immersed in Fresh Water at 70 Deg. Fahr. Reabsorption tests were made at the end of 1, 24, 48, 72 and 117 hours. The observations were all concordant, and hence only the data obtained from the 24-, 48- and 117-hour periods have been plotted in Fig. 2. Here the relative reabsorptive powers of pine and fir are much more nearly alike than in the case of the treatment in saturated air. Yet even here it will be noted that in all cases the reabsorptive power of the fir is slightly greater than that of the pine.

While the time required for fiber saturation is not definite in the case of timber immersed in water, yet an inspection of the curves of Fig. 2 shows clearly that such saturation undoubtedly occurs, and that it is only a matter of time, whether in the case of columns or beams of timber, even though previously air-dried, for them to be reduced to the character of green wood. It would seem, then, that conclusions relative to the design of timber liable to submersion are similar to those drawn at the close of the discussion of the effect of treatment by saturated air.

Comparison of Figs. 2 and 3 beyond the first half inch from the exposed end shows that the rapidity of reabsorption is much less when the wood is immersed in water at 70 deg. fahr. than when exposed to air saturated at 120 deg. fahr. In detail it will be noted that 24 hours in water are required to produce approximately the same reabsorption as 3 hours' treatment in moist air, and that the reabsorption after 48 hours' submersion is approximately that attained during a 24-hour exposure to moist air.

Effect of Reabsorption on the Compressive Strength

As previously noted, the blocks under investigation were 2 in. by 2 in. by 8 in. After treatment a section 1 in. thick was removed from each end, thus giving a specimen 6 in. long for the compression tests. The ends were squared in a metal

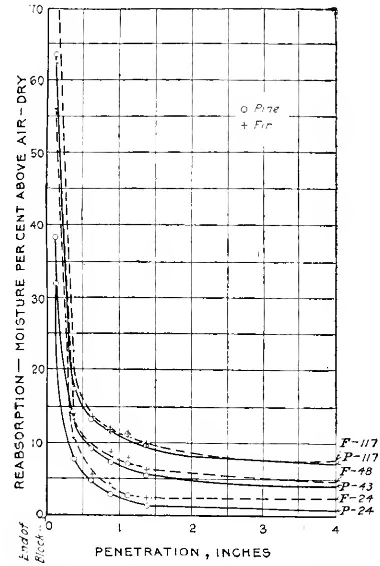

Fig. 2 Reabsorption of Specimens when Completely Immersed in Fresh Water at 70 Deg. Fahr.

P-24 indicates pine treated 24 hr.; *F*-48, fir treated 48 hr.; other symbols to be similarly interpreted.

miter box so that the faces subjected to pressure were as nearly parallel as possible. The tests were conducted on a 100,000-lb.-capacity Olsen testing machine having a ball-and-socket joint on the moving head. This should completely obviate the introduction of any eccentricity of loading, and the failure of the specimens would indicate a pure compression stress.

After failure a quarter-inch section was removed from the specimen at the point of fracture, and from this the moisture content was obtained as previously described.

Figs. 3 and 4 have been prepared to show the relations, if any exist, between the actual moisture content and the crushing strength of the two woods under discussion.

All of the fir tested, with two exceptions, showed from 12 to 17 rings per inch measured radially; the summer wood comprised from 30 to 60 per cent of the total growth; the air-dry density ranged between 31 and 36 lb. per cu. ft.

The pine under investigation showed from 7 to 10 rings per inch measured radially. The summer wood ranged from 30 to

50 per cent of the total growth. The air-dry density was between 32 and 36 lb. per cu. ft.

Pine specimens *S* (three in number, see Fig. 4) had but 6 rings per inch, showing only 25 per cent summer wood, and an air-dry density of about 30 lb. per cu. ft. It is evident that the wood from which these were cut should be classed as "sound" rather than as "dense" southern pine according to the A. S. T. M. standards.

The moisture-strength relations for the fir and pine will now be taken up separately and later compared.

Douglas Fir. The most superficial glance at Fig. 3 will very clearly show that the compressive strength of the wood falls

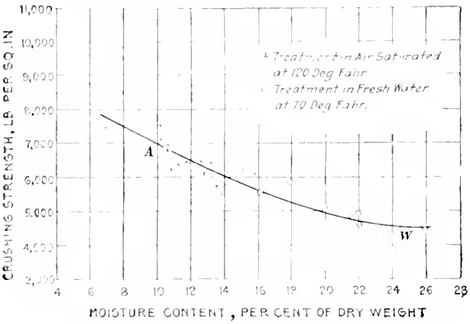

Fig. 3 Relation between Moisture Content and Crushing Strength of Douglas Fir

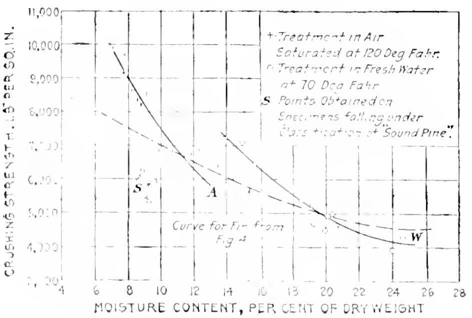

Fig. 4 Relation between Moisture Content and Crushing Strength of Yellow Pine

as the moisture content increases. The material is of organic origin and subject consequently to manifold variation. Hence it is only to be expected that the plotted points shall assume a more or less "gun-shot" arrangement. In such a case the choice of the best representative curve is open to all the elements of variation arising in the personal equation of the investigator. The curve drawn, however, is assumed by the writer to be fairly representative and is at least indicative of certain fundamental relations.

The data were obtained as previously explained from tests made on specimens subjected to radically different treatments. In the case of the fir, nevertheless, the resulting graph is evidently a continuous line. The inclination is somewhat sharper with the lower moisture contents and flattens out, becoming approximately horizontal at a moisture content of about 25 per cent. This corresponds very closely with the fiber-saturation point previously referred to and would seem to bear out the existing theory that only the "imbibed" moisture affects the strength in compression.

While it must be kept in mind that the values of the strengths here recorded are in no way indicative of the proper constants for use in design, yet it is felt that certain of the relations apparent are of fundamental truth. It will be noted that the treatment of wood by exposure to air saturated at a temperature of 120 deg. fahr. results in a compressive strength of about 25 per cent less than the strength of air-dry timber. This reduction appears at about 14 per cent moisture content.

Submersion in water at 70 deg. fahr. for a period of 117 hours produces at the point of fracture a moisture content of 26 per cent, thereby reducing the strength to a value about 40 per cent below that of air-dry wood of the same quality.

Yellow Pine. The data recorded in Fig. 4 offer certain marked variations from those shown for fir in Fig. 3, the curve for which has been transposed to this plot as a dash line. It is very obvious that the data obtained from the pine yield plotted points which cannot be satisfactorily represented by a single line. The data from the water-soaked specimen, marked *W*, yield a fairly determinate curve. The data from the specimens exposed to the moist air, marked *A*, might be reasonably well represented by a variety of lines. However, it seems fair to presume that the two lines will be of the same general type, even though they are discontinuous. Such has been the assumption used as a guide in drawing the representative lines.

The generalizations for the pine are quite similar to those drawn from the graph characteristic of the effect of reabsorption by the fir. The decrease in strength is at first quite rapid with the increase of moisture content. It later flattens, becoming nearly horizontal at about 25 per cent moisture content, again indicating this value as the fiber-saturation point.

The rate of decrease in strength seems to be more rapid for yellow pine than for fir. In the case of the specimens investigated this decrease becomes about 35 per cent after 24 hours' exposure to air saturated at 120 deg. fahr. It is only fair to suggest that this decrease may not be due entirely to moisture, which point is discussed in a later paragraph.

Due to the extremely rapid reabsorption, no points were obtained for the soaked specimens between the air-dry condition and about 14 per cent of moisture. The graph *W* as drawn, however, if extrapolated as a straight line will pass very close to the data obtained from the air-dry material. This graph shows that the moisture content of about 25 per cent which was present 1 in. from the exposed end after a soaking of 117 hours, resulted in a strength nearly 60 per cent below the strength of the air-dry material.

Reasons for the Discontinuity of the Graph. The wood treated to the moist air at 120 deg. fahr. was tested immediately upon removal from the steamer. It was warm when subjected to pressure; in some cases the temperature of the inner portions was probably at least 100 deg. fahr. Pine is a very resinous wood. At the temperatures maintained this resinous material will soften, and some of the normally solid constituents will undoubtedly become actually liquefied. The portions normally in the state of a liquid of high viscosity will undoubtedly have their viscosity considerably lowered. The effect of this action will be that of a general removal of the stiffening action of the cell contents and a possible lubricating effect tending to permit a greater freedom of movement between cells which are poorly adherent because of incidents of growth. This effect is additive to the general effect of the absorption of moisture and may well explain the sharp pitch of the curve *A*.

The temperature of the water (70 deg. fahr.) used for the soaking treatment is probably insufficient to produce the above-noted effect. In fact, the temperature is approximately that at which the air-dry specimens were tested. It would seem, then, that the temperature factor may reasonably be eliminated from a discussion of the curve W. If such be the case, it is to be expected that a given moisture content when obtained in the water at 70 deg. fahr. will show a less marked weakening effect than does the same moisture content when resulting from exposure to moist air at 120 deg. fahr. Observing the conditions at a moisture of 14 per cent, such is found to be the case. The difference between the ordinates of curves A and W at this degree of saturation may well be taken to represent the weakening effect of heat due to softening of the resinous compounds by a heating for 24 hours at 120 deg. fahr.

Since the quantity of resinous matter in the Douglas fir is much less than that in the pine, this temperature effect would doubtless be absent and the resulting graph be a continuous curve, as was found to be the case.

The specimens giving the points marked S are of considerable interest as an exemplification of the fact that wood of coarse growth, low percentage of summer wood, and corresponding lesser density yields a lower compressive strength than when the reverse conditions obtain. Though the number of pieces coming in this category is small, yet the facts point strongly toward a justification of the acceptance of the so-called "density rule" of the standards of the American Society for Testing Materials.

Comparisons and General Conclusions

In the interpretation and subsequent use of the data furnished in this paper, it must be kept in mind that the specimens tested were brought in the open market of Boston; that no special selection of material was made except so far as was necessary to obtain specimens of reasonably straight grain, free from knots and serious defects; that tests were made on small specimens, limited in number and selected from a very small initial quantity of lumber; that in consequence of the above facts the results must be considered comparative and qualitative rather than definitely quantitative.

With all the above in mind, an analysis of the preceding data as shown by the accompanying plots seems to justify the following statements:

In the air-dry condition with approximately equal moisture contents the compressive strength of hard pine is about 25 per cent greater than that of Douglas fir.

When exposed to air saturated with water vapor at 120 deg. fahr. and when immersed in fresh water at 70 deg. fahr., the moisture reabsorption of air-dried wood is greater and more rapid in the case of fir than in the case of pine.

The temperature effect on strength decrease is of more importance on pine than on fir.

Pine shows a more rapid decrease in strength with the moisture increase than does fir. [The more rapid reabsorption by fir tends to offset this effect when the time element is used as a basis, so that for a given time of treatment the pine remains the stronger, although the strengths tend to approach each other with more extended treatment.]

For moisture contents above 11 per cent when due to reabsorption from air saturated at 120 deg. fahr., the fir is stronger in compression than is the pine. The same relation appears for moisture contents greater than 20 per cent when due to soaking in fresh water at 70 deg. fahr.

EFFICIENCY OF GEAR DRIVES

An Accurate Method of Testing

Member of the Society

and

F. W. ROYS, WORCESTER, MASS.

Non-Member

Apparatus for determining the efficiency of gears and other drives has recently been developed and used for making tests in the Mechanical Engineering Laboratories of the Worcester Polytechnic Institute. The fundamental principle of the apparatus consists in the direct measurement of the loss of power in the gear drive instead of the usual method of determining the input and output and subtracting one from the other.

Since the efficiency of good geared drives is relatively high, the input and output are very nearly equal, and any small errors in the measurement of these relatively large quantities will make a very large per cent error in the difference, which is the power loss.

It is therefore evident that a method by which the loss may be measured directly and independently of the input and output would be very much more accurate.

Theory of Apparatus Used in the Tests

The theory of the apparatus which was used in the tests is as follows: An electric motor is so hung in a cradle that both its armature and field are free to turn. The armature shaft is connected directly to the pinion gear shaft and the driven shaft directly to an Alden absorption dynamometer. The reaction of the motor field is balanced by the action of the absorption dynamometer through a simple lever. The arms of the lever are accurately proportioned to the ratio of the gears.

The general idea of the apparatus is as follows: An electric induction motor is hung in a cradle on double roller bearings, and an arm attached to the motor casing makes a cradle dynamometer. The motor shaft is connected directly to the drive shaft and an Alden dynamometer is put on the driven shaft. These dynamometers are so arranged that the force exerted by the end of the arms is downward. The arms of the dynamometers are of equal length and at the end of each is a fixed knife edge. A lever with three knife edges mounted upon it has the two outer knife edges adjusted so that the distance between them is equal to the distance (horizontal) between the dynamometer knife edges. The third knife edge divides this distance into segments whose ratio to each other is the same as the gear ratio. These three knife edges lie in the same straight line. The lever is now placed directly over the line between the dynamometer knife edges, and is supported by the third knife edge which rests on platform scales. The end knife edges of the lever are connected to the dynamometers in such a way that the high-speed dynamometer is connected to the long arm of the lever. A counterweight and a rider weight are mounted upon the lever. See Fig. 1.

Method of Testing

The method of testing, so far as the operation of the lever

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

system is concerned, is identical for all tests, and therefore the explanation of its action is made perfectly general.

The center of gravity of the Alden brake was very nearly in the horizontal plane, so that a slight movement of the arm did not measurably affect its balance. The cradle dynamometer was so loaded that its center of gravity was only a short distance below the shaft center, and a load of 2 lb. at the end of the arm was enough to entirely upset its equilibrium. The lever was then placed in position as described above and statically balanced by means of the counterweight shown in Fig. 1. A long pointer attached to the lever showed the position of the system relatively to the initial condition of balance.

When the rider weight W was in its initial position, the load of moment, and when corrected for the speed of the apparatus it is a measurement of the power loss.

Here the input power is automatically balanced against the output, and any little change in the latter is immediately taken care of by the motor, and it is impossible for the apparatus to be out of balance except by the amount of the transmission loss. This is the feature of the method which distinguishes it from all others.

The power transmitted by the drive may be computed by noting the change in the load P_2 on the platform scales, and such computations will be shown later.

In operating it was found necessary to start the apparatus and let it run for several minutes before taking note of the

P (see Fig. 1) was noted as the initial reading of the platform scales.

The variables entering into the balance of this apparatus are then the forces P_1, P_2 and P_3, and the displacement of the rider weight. P_3 may be measured at any time while the apparatus is in operation, and so may the displacement of the rider weight.

It should be noted here that the amount of P_2 has nothing to do with the calculation of the power loss, which is found as follows:

METHOD OF MEASURING POWER LOSS

It will be seen from the preceding description and from Fig. 1 that $P_1x = P_2y$ for 100 per cent efficiency; but since the efficiency is never 100 per cent, P_1x must exceed P_2y by the amount necessary to overcome the loss in moment. This difference immediately upsets the balance of the lever, of course, but equilibrium may again be restored by shifting the position of the rider weight in the proper direction. This displacement of the rider weight is therefore a measurement of the change initial position of the lever. The zero reading was frequently checked during the period of testing.

EFFICIENCY TEST OF BEVEL-GEAR DRIVE

Data of Gears and Apparatus. The gears were 5 per cent nickel steel, case-hardened, 5 pitch, 1½-in. face. They were cut by the Brown & Sharpe Mfg. Co. and were mounted by them on ball bearings especially designed for testing purposes. Fig. 2 shows the apparatus set up for this test. Following are the preliminary data employed:

Number of teeth in gear.............................52
Number of teeth in pinion...........................14
Ratio, 52 ÷ 14....................................3.714
Total length of lever between outside knife edges (see Fig. 3)......................................3.95 ft.
Length of long arm of lever............3.112 ft. = 37.344 in.
Length of short arm of lever...........0.838 ft. = 10.056 in.
Length of dynamometer arms........................31.5 in.
A force of 2 lb. at 31.5 in. is equivalent to 1 hp. at 1000 r.p.m., for which the expression 1 hp_{1000} will be used.

Calculation of Horsepower Loss from Movement of Rider. Referring to Fig 3, a force of 2 lb. at $P_1 = 1$ hp_{1000}. Therefore $2 \times 37.344 =$ in-lb. of moment in lever necessary for 1 hp_{1000}, and if the rider weight is 3 lb., then for this to balance 1 hp_{1000}, $3x$ must equal 2×37.344, whence $x = 24.893$, and therefore a movement of 24.893 in. of the rider is equivalent to 1 hp_{1000} for a 3-lb. rider.

If the rider weighs but $1\frac{1}{2}$ lb., then the same displacement means only $\frac{1}{2}$ hp_{1000}. A paper scale was made according to these figures and was fastened to the lever. The readings for hp. loss were taken from it throughout the test.

Calculation for Horsepower Input. Referring to Fig. 3, since the initial load of P_3 was taken with the rider weight W already on the lever, a change in the position of W does not change P_3, but merely changes the moment. Therefore, in moment equations of the lever, regardless of where the center of moments is taken, the arm of the moment of W is always the distance from the zero position.

The force P_1 is a measure of the input power if the speed is known, and it is merely necessary to calculate this value in order to solve the problem. Considering the moment equation of the lever, we have

$$0.838P_3 - 3.95P_1 + Wx = 0$$

whence

$$P_1 = \frac{0.838P_3 + Wx}{3.95}$$

If $W = 3$ lb.,

$$P_1 = 0.2122P_3 + 0.759x$$

if $W = 1.5$ lb.,

$$P_1 = 0.2122P_3 + 0.379x$$

x being the displacement of W measured in feet.

Referring to Table 1, for accuracy of recorded data the values in column 5 (x ft.) and column 10 (rider hp_{1000}) should vary together, since they both refer to the displacement.

Column 10 is recorded for one purpose and read from the paper scale directly in hp_{1000}; while column 5 is recorded for

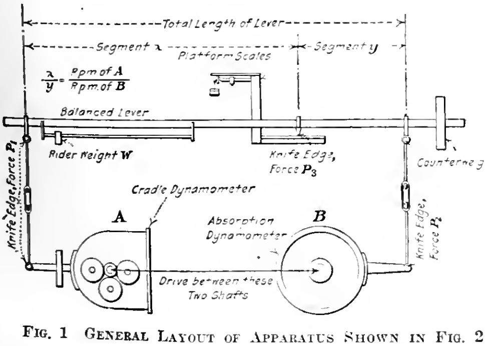

Fig. 1 General Layout of Apparatus Shown in Fig. 2

another purpose and the measurement is recorded in feet measured by an ordinary rule.

It is necessary to read the values recorded in column 10 with as great accuracy as possible, but the approximate distance to the mean position as determined in column 10 is as close as it is necessary to record the values of column 5.

The values in column 10 after correction for speed give the total loss in power and become therefore the whole of the numerator of the equation for *loss* of efficiency, namely,

$$\text{Loss of efficiency} = \frac{\text{Hp. loss}}{\text{Hp. input}}$$

These values for hp. loss are recorded to three significant figures, but the third is somewhat in doubt, and therefore the absolute accuracy is only through two significant figures.

In figuring hp. input it is necessary to use the value P_1, which is obtained by means of the equation $P_1 = 0.2122P_3 + 0.759x$, where x is the value in column 5. The maximum variation in feet from the mean position (column 10) is less than 0.1 ft., but suppose that it was 0.1 ft.; then column 5 might have been 1.8 instead of 1.7 as in the first recorded line.

To see what the effect of such a discrepancy would be,

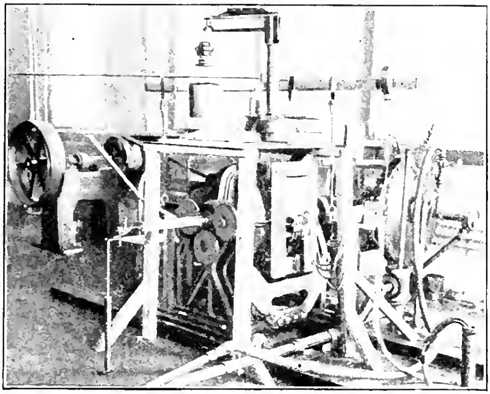

Fig. 2 Apparatus for Testing the Efficiency of Bevel-Gear Drives

the following computations have been made, taking $x = 1.8$ and $x = 1.7$, respectively:

$$P_3 = 200; \quad 0.2122P_3 = 42.44$$
$$P_1 = 42.44 + 0.759x$$
$$= 42.44 + (0.759 \times 1.8) \text{ or } = 42.44 + (0.759 \times 1.7)$$
$$= 42.44 + 1.36 \text{ or } = 42.44 + 1.29$$
$$= 43.80 \text{ or } 43.73.$$

As hp_{1000} input $= \frac{1}{2} P_1$, then hp_{1000} equals either 21.90 or 21.865, and

$$\frac{\text{Hp. loss}}{\text{Hp. input}} = \frac{\text{Rider hp}_{1000}}{\text{Input hp}_{1000}}$$

whence

$$\text{Loss of efficiency} = \frac{0.746}{21.90} \text{ or } \frac{0.746}{21.865}.$$

It is thus seen that, measuring as accurately as possible, the numerator is only accurate to the second place, the third being in doubt; and that the second place in the denominator is sure, and the third fairly sure, although considered in doubt. Therefore the denominator is as accurate as the numerator.

The numerator is as accurate as the apparatus will allow data to be read, and therefore the inaccuracy of the data of column 5 has no effect on the final accuracy of the work.

In Test No. 1, the data of which are given in Table 1, practically no lubrication was used, the gears having been washed off with gasoline. Previous to this there had been oil and graphite on the gears, and some of the graphite still remained on the teeth. However, after running for a while they were practically non-lubricated. The 3-lb. rider had to be used in this case because of the amount of the friction loss, which, by the way, was sufficient to cause the gears to heat considerably.

Table 1 gives only a few of the results actually obtained, for

the apparatus was started time after time and the balance by the rider gave the same results over and over again.

The next test was made to see how much the efficiency would be increased with good lubrication. Accordingly some heavy oil and flaked graphite were mixed and used as a lubricant. The efficiency was so much increased that the $1\frac{1}{2}$-lb. rider weight was sufficient, and again it was found that the same results were obtained time after time. Later, after the graphite and oil had become more perfectly blended, another test was made.

The efficiency curves for these three tests are all given in Fig. 4. The difference between the results of non-lubricated and lubricated conditions is perfectly clear. The test with the more perfect blending of the lubricant showed results identical with the previous one, except as indicated by the dash line at the end of the upper curve. This showed that the lubricant

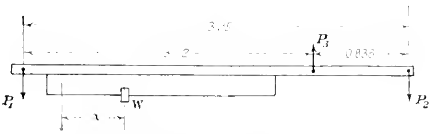

Fig. 3 Dimensioned Sketch of Apparatus

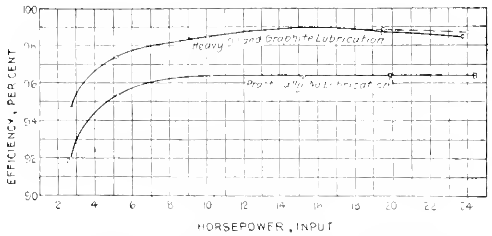

Fig. 4 Horsepower-Efficiency Curves of Bevel-Gear Drive

Gear ratio, 26 to 7; r.p.m. of pinion, about 1200

was not squeezed out from between the teeth at quite so low a pressure.

The form of the curves and the consistency of the readings convinced the experimenters that very reliable results had been obtained. This was also the case regarding tests made of the efficiency of a worm-gear drive and reported in the complete paper.

It is accordingly concluded that this apparatus will measure accurately the efficiency of any positive shaft drive where both shafts are rotating at constant speed, and that it seems to be the best method yet devised for testing gear drives for efficiency, since it measures directly the actual power loss.

While this paper has described only tests of bevel- and worm-gear drives, tests of other drives have been made, and the method is applicable to all types.

The depth of a pile seems to have a good deal to do with the development of spontaneous combustion. A 10-ft. pile is very likely safe for most bituminous coals, provided other conditions are not unfavorable; but 20 to 25 ft. is probably more or less dangerous. In the New York Edison Co.'s yard at Shadyside, N. J., where coal is stored in piles reaching heights up to 35 ft., spontaneous combustion gives trouble. (*Power*, April 16, 1918, p. 537.)

A FOUNDRY COST AND ACCOUNTING SYSTEM

By WILLIAM W. BIRD, WORCESTER, MASS.

Member of the Society

The work in Shop Management at the Worcester Polytechnic Institute is in the nature of a laboratory course, and experimental work in accounting and cost keeping is made possible by the commercial foundry and machine shop of the Institute, known as the Washburn Shops.

The object of this paper is to present an outline of the cost and accounting system which has been developed as a result of experiments carried on in connection with the foundry at the Institute.

The first problem was to determine the number of independent variables and how the dependent ones were related to them. After several years it was decided that the three most important items were Core Labor, Molding Labor, and Pounds of Castings Produced, and that each of the other items of cost was a function of some one of these three independent items.

Ledger accounts were opened for each one of the items, and by careful inventories at the beginning and end of each year the exact annual cost for each item was worked out.

The next problem was to determine a proper production credit for the individual accounts for each month, based on factors secured by previous records. The general scheme being to charge an account with the amount of the purchases for that month and credit it with a fair estimate of what ought to have been used for that month's work. These production credits are charged to another account, as will be explained later.

All expenses are charged to the Expense Account and the production credit for expense ought to be large enough to more than balance the charges, thus creating a balance to the good, known as Expense Reserve.

Core Work

The material required for core work was found to average about 30 per cent of the core labor, hence to make the production credit for core work for a month it was only necessary to secure from the payrolls the amount paid to the core makers for that month and add 30 per cent for the supplies used.

Molding

All of the items of cost in the foundry excepting the metal, melting and core work, were divided into two classes: Supplies or all the materials used in connection with molding, such as sand, facing, etc., and Expense, or all charges for management, office work, power and other overhead items, cleaning, flasks, etc.

At the present time we are basing our production credits for supplies on 6 per cent of the molding labor and the expense on 75 per cent, the molding labor for the month being secured from the payrolls, all of the molders being grouped for this purpose.

Metal and Melting

In order to secure the exact tonnage for each month it was

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

found necessary to make an inventory on the first of each month of the castings on hand. This, however, is only a close estimate of the weight of these castings. A record of the castings sold during the month gives the tonnage also. Correcting this for the change in the inventory of castings, gives the production in pounds for the month.

The cost of melting was found to vary directly with the pounds of castings produced, and therefore the melting production credit for the castings produced each month is found by multiplying the pounds produced by the melting factor, which at present is 30 cents per 100 lb.

A careful record for a number of years of the castings produced and of the pig and scrap used, gives the data for the factors to be employed in making up the production credits for the metal used each month. At present we use 75 per cent of the pounds produced as the proper weight of pig iron, and 37½ per cent for scrap iron. These factors take care of the shrinkage and the defective castings, as these are replaced without credit to the foundry.

Knowing the weight and cost of the pig iron purchased each month, this cost including all charges for freight and teaming, the cost per 100 lb. is made up. Multiplying this by 75 per cent of the pounds produced, we have the production credit for pig iron. The production credit for scrap iron is worked out in the same way.

The problem of handling the difference between the material purchased and what was actually used was solved by making the ledger balance a book inventory for material accounts and a reserve for the expense account, as stated.

The next problem of how to adjust the difference between the castings sold and the castings produced was solved as follows:

Two ledger accounts were opened—Foundry Sales and Foundry Production. The first is credited with the monthly sales and charged with the factor cost of the castings sold. The balance of this account is the factor gain and gives a definite line on the profits.

Foundry Production is charged each month with the total amount of the production credits and credited with the factor cost of the castings sold, the monthly ledger balance giving the value of the castings on hand. In fact, the value of the castings on hand is worked up first from the inventory made on the first of each month, and the factor cost of castings sold is simply the amount required to make the account show the proper balance.

To show the exact working of this system, the figures for three months will be given—a good month, a fair month, and a poor one. As these months did not come in this exact order, it was necessary to make a few changes in the figures, but they are substantially an exact record.

Starting with a clear record on July 1, with no castings on hand, we have:

Balance Sheet, July 1

Assets		Liabilities	
Bills receivable..........	$13,187.20	Capital..	$20,000.00
Cash....................	6,331.06	Surplus....	3,654.13
Metal and supplies.......	1,333.03	Bills payable..	2,197.16
Equipment..............	5,000.00		
	$25,851.29		$25,851.29

The inventory on August 1 gave 3500 lb. of castings on hand, the sales record gave 122,541 lb. sold, the production was therefore 126,041 lb. The core labor was $443.89 and the molding labor $1863.84. 117,180 lb. of pig iron cost $2381.86 and the scrap iron cost $1.50 per hundred delivered in the yard. These are all of the data necessary for making up the following:

Monthly Foundry Record, July

Purchases	Division	Factor	Production credits
$443.89	Core labor..	100%	$443.89
127.00	Supplies.......	30%	133.17
1,863.84	Molding labor.......	100%	1,863.84
156.29	Supplies..	6%	111.83
1,303.03	Expense....	75%	1,397.88
612.17	Metal—melting....	30c.	378.12
2,381.86	117,180 lb. pig iron...	75%	1,918.98
737.62	$1.50 per 100 scrap iron....	37½%	708.98
$7,625.70	Total—Factor Cost of Production		$6,956.69

The factor cost was $5.52 per 100 lb. for castings produced and the castings on hand at the end of the month were valued at this rate. 3500 lb. at $5.52 gives a correction of $193.20. This is the difference in the value of castings on hand at the beginning and end of July.

Factor cost of production........	$6,956.69
Correction	193.20
Factor cost of castings sold...	$6,763.49
Sales for July...............	7,350.31
Factor gain for July..........	$586.82

The Expense Reserve is found by subtracting the charges $1303.03 from the credits $1397.88, giving $94.85 for the month.

The Trial Balance of the Ledger gives the necessary data for the following:

Balance Sheet, July 31

Assets		Liabilities	
Bills receivable.........	$13,288.31	Capital....	$20,000.00
Cash....................	6,299.50	Surplus.............	3,654.13
Castings	193.20	Bills payable.......	2,542.10
Metal and supplies.......	2,096.89	Expense reserve......	94.85
Equipment..............	5,000.00	Factor gain...	586.82
	$26,877.90		$26,877.90

On September 1 we had 4000 lb. of castings on hand, and sold in August 132,773 lb. The production was therefore 133,273 lb., as we had 500 lb. more on hand at the end of the month than at the beginning.

Monthly Foundry Record, August

Purchases	Division	Factor	Production credits
$522.61	Core labor......	100%	$522.61
45.50	Supplies...	30%	156.78
1,968.90	Molding labor......	100%	1,968.90
44.83	Supplies.........	6%	118.13
1,426.64	Expense...	75%	1,476.67
382.21	Metal—melting.......	30c.	399.82
2,759.65	107,620 lb. pig iron........	75%	2,568.84
701.70	$1.75 per 100 scrap iron........	37½%	874.62
$7,852.04	Total—Factor Cost of Production.		$8,086.37
	Inventory correction.......		$49.60
	Factor cost of castings sold...........		$8,036.77
	August sales................		8,179.51
	Factor gain—August.....		142.74
	Factor gain—July 1-Aug. 1.......		586.82
	Factor gain—July 1-Aug. 31.......		$729.56

The Expense Reserve for August is \$1476.67 minus \$1426.64, or \$50.03, making the total Reserve, August 31, \$144.88.

BALANCE SHEET, AUGUST 31

ASSETS		LIABILITIES	
Bills receivable	\$14,016 50	Capital	\$20,000 00
Cash	5,750 82	Surplus	3,654 13
Castings	242 80	Bills payable	2,394 14
Metal and supplies	1,912 59	Expense reserve	144 88
Equipment	5,000 00	Factor gain	729 56
	\$26,922 71		\$26,922 71

On October 1 we had 15,000 lb. of castings on hand and sold during September 124,557 lb. The production for the month was therefore 135,557 lb.

MONTHLY FOUNDRY RECORD, SEPTEMBER

Purchases	Division	Factor	Production credits
\$542 00	Core labor	100%	\$542 00
65 46	Supplies	30%	162 60
2,016 70	Molding labor	100%	2,016 70
144 94	Supplies	6%	121 00
1,326 58	Expense	75%	1,512 53
541 90	Metal—melting	30c.	406 67
2,834 85	116,980 lb. pig iron	75%	2,160 37
1,763 52	\$1.75 per 100 scrap iron	37½%	889 60
\$9,235 95	Total—Factor Cost of Production		\$8,111 47

Inventory correction	\$654 20
Factor cost of castings sold	\$7,457 27
September sales	7,485 76
Factor gain—September	28 49
Factor gain—July 1-Sept. 1	729.56
Factor gain—July 1-Sept. 30	\$758 05

The Expense Reserve for September is \$1512.53 minus \$1326.58, or \$185.95, which added to \$144.88 makes the total reserve \$330.83.

BALANCE SHEET, SEPTEMBER 30

ASSETS		LIABILITIES

In order to keep comparative data before the foundry officials and aid them in the analysis of the monthly records, the table of monthly averages (in the next column) is filled in as soon as possible after the first of each month.

In order to keep a line on the book inventories, the table following that of monthly averages is filled in each month. These figures show the changes in the several accounts and indicate in a way how the factors are working. If an account is steadily growing, as the Pig Iron Account shows in this table, we are either accumulating pig iron or the factor is too small. Core Supplies here shows a constantly diminishing amount, and either we are reducing our supplies or the factor is too large. An exact inventory can be made at any time to check up the book inventory and a change made in the factor if necessary.

MONTHLY AVERAGES

Melting supplies	+234 05	−17.61	+135.23
Pig iron	+462.88	+190.81	+374.48
Scrap iron	+28.64	−172.92	+873.92
Net change	+763.86	−184.30	+1,310.43
Beginning of month	\$1,333.03	\$2,096.89	\$1,912.59
End of month	\$2,096.89	\$1,912.59	\$3,223.02

The following samples of ledger pages will show just how the bookkeeping is done:

FOUNDRY SALES

July 31	Factor cost—sales	\$6,763 49	July 31	Sales	\$7,350.31
	Balance	586.82			
		\$7,350.31			\$7,350.31
			Aug. 1	Balance	586.82

The balance of this account gives the factor gain and is the total amount from the beginning of the fiscal year.

FOUNDRY PRODUCTION

Aug. 1	Balance	\$193 20	Aug. 31	Factor cost—sales	\$8,036.77
31	Factor cost—production	8,086 37		Balance	242.80
		\$8,279 57			\$8,279.57
Sept. 1	Balance	242 80			

The balance on this account is the exact inventory of the castings on hand, valued at the factor cost for the month.

Foundry Expense

Sept. 30	Purchases....	$1,326.58	Sept. 1	Balance...	$144.88
	Balance.....	330.83	Sept. 30	Production credits.	1,512.53
		$1,657.41			$1,657.41
			Oct. 1	Balance ..	330.83

The balance on this account is the amount that the Reserve has built up during the year.

Pig Iron

July 1	Balance..........	$331.20	July 31	Production credit..	$1,918.98
July 31	Purchases.....	2,381.86		Balance.....	794.08
		$2,713.06			$2,713.06
Aug. 1	Balance........	794.08			

The balance on this account is the book inventory for the pig iron on hand.

Thus every ledger balance has a definite meaning, either an inventory, a reserve or a gain, and the complete balance sheet for each month can be made up in a few minutes from the regular trial balance. All of the work can be done by the regular clerical force and requires but a small amount of extra time. No expert accountant or efficiency engineer is needed.

The closing of the books at the end of the fiscal year introduces several interesting problems.

The Molding and Core Labor Accounts take care of themselves as the charges and credits are the same and they are therefore always balanced. The material accounts are first corrected by introducing the exact value of a carefully made inventory. This gives us the real cost for the material which has been actually used during the year. The next step is to adjust the production credit for the twelve months to the final charge. The difference between the two sides of the ledger is the amount of the adjustment and may be either plus or minus. The net result of all these factor adjustments is carried to Expense Reserve and will either increase it or decrease it, as the case may be.

Bad accounts, depreciation charges, discounts, premiums, special expenses or any other accounts which need to be absorbed, are all transferred to Expense Reserve and the net balance of the account is carried to Foundry Sales either increasing or decreasing the Factor Gain and this balance then becomes the real Sales Gain for the year.

In conclusion, we would say that the system as outlined is giving good satisfaction, the results are fairly accurate, and the comparative monthly data thoroughly reliable as a signal system.

A state testing and experimental institution for the mining industry has been formed in Minneapolis, Minn., and it will coöperate with the mining section of the University of Minnesota. Special attention will be paid to the treatment of ores with a comparatively low percentage of iron, and which at present cannot be industrially exploited with advantage, so that such ores may be enabled to play their part in the iron industry of the country. Particular attention will be paid to hematite containing 30 per cent to 50 per cent iron, to magnesite iron and to titaniferous iron ore, of which large deposits are to be found in the northeastern portion of Minnesota, and to manganese ore with a small percentage of manganese—all problems of great importance to the future of the American iron industry.

INVESTIGATION OF THE USES OF STEAM IN THE CANNING FACTORY

By JULIAN C. SMALLWOOD, BALTIMORE, MD.

Member of the Society

It is not the writer's purpose to deal in this paper with the economies possible in the generation of steam in the canning factory. Although it would well repay the packer to inform himself on this subject, since in the boiler room any amount up to 50 per cent of his coal may be wasted, the principles of economical boiler-room operation are well understood by mechanical engineers and are no different in the canning factory from any other. The principles and the best practice in the use of steam, on the other hand, are not common knowledge, and will therefore engage the writer's attention.

Uses of Steam in Canning Factories

First in an enumeration of the various packing-house units requiring steam are engines to turn the lineshaft and operate cranes and conveyors, and, possibly, pumps for supplying water. Next in order is the apparatus to give the raw material a preliminary heat treatment. In the case of tomatoes, this is a scalder which loosens the skins; in the case of peas, beans, spinach, etc., it is a bleacher which fixes the color of the product and washes away impurities and partial decay. At this stage some goods are placed in the cans, but for others heat must first be applied in bulk in order to evaporate water and concentrate the product. For example, tomato pulp or paste must first be boiled down, as must also fruit juices in the manufacture of jellies and preserves. If the material requires such reduction, it is next introduced into a kettle supplied with a steam jacket for evaporation, or a tank supplied with steam coils, or into some form of evaporator using steam as a source of heat for evaporation. If the material does not require such reduction, it must next be sent through an exhaust box the chief function of which is to produce a partial vacuum in the capped can by expanding its contents previous to capping. The expansion is accomplished by heating the cans by direct contact with steam in the exhaust box. After the cans are capped they are packed in metal cages and placed in a "process kettle" or retort, where they again are subjected to steam heat for the purpose of sterilizing and cooking. Finally, upon removal from the process kettles, the packed cans must have their heat removed, which is usually effected by a water bath and which completes the heat processes of production.

Analysis of the Heat Distribution

An analysis of the heat distribution leads to the following conclusions: First, as a rule, the mechanical power required is comparatively small, and this limits the possibilities of exhaust steam. Second, except for products that must be reduced by evaporation, the directly useful heat functions simply by elevating the temperature of the raw material from that of the room up to whatever temperature is carried in the process kettle. Assuming, for example, that the temperature of the

---

For presentation at the Spring Meeting, Worcester, Mass, June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

raw material is 80 deg. fahr. and the temperature of the process kettle is 212 deg., the difference is 132 deg., and the useful heat in the whole process of canning is numerically equal to the total weight of the can contents multiplied by 132 deg. multiplied by the specific heat. To this, of course, must be added the heat of vaporization when the product is reduced, which, however, is only the case for certain products.

This may seem a startlingly simple conclusion to be formed from a complex problem, and yet, truly, there is no other one. Cooking and sterilizing are merely a matter of elevating a temperature and maintaining it. Once the temperature is attained it can be held, under ideal conditions, without further consumption of heat. Heat consumed for any other purpose is either for an auxiliary process, or is a total loss through inefficiency of the main process. This principle finds an application in a small way, in domestic kitchens, in the fireless cooker. The old-fashioned stove and the more recent gas range both waste enormous amounts of heat, because after the temperature of the cooking material has been raised, heat continues to be consumed, and is wasted by radiation from the containing vessel and by convection currents.

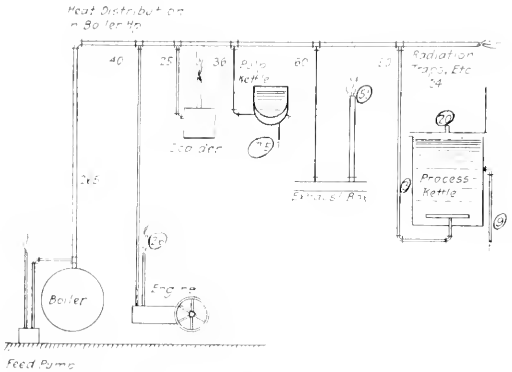

FIG. 1 DISTRIBUTION OF HEAT IN A FACTORY CANNING TOMATOES

Similarly, in the canning factory, from the time the raw material enters the exhaust box up to the time it leaves the process kettle, the one desirable effect is the elevation of temperature. In the exhaust box this is partially accomplished, possibly with the expenditure of a disproportionate amount of steam. Between this stage and the process kettle the can is being capped and packed in the crates, during which handling it may radiate some heat which will have to be restored. Finally, the sealed cans are placed in the process kettle. Heat is transferred to them and, incidentally, radiated from the surface of the kettle, blown right through the kettle (especially if an open water bath is used), and wasted through an overflow of hot water.

For the purpose of obtaining an idea of the quantitative values of these heat transfers, Fig. 1 has been prepared showing the distribution of heat in a packing house putting up tomatoes. An arrangement using steam inefficiently has been purposely shown in order to indicate the possibilities. It is assumed that this plant is equipped to handle 10,000 baskets per day of 12 hours, that the tomatoes are canned whole, and that skin-and-core pulp is put up as a by-product. A fair value for the yield is seven No. 3 cans of whole tomatoes per basket, and one No. 3 of pulp. This will make a total of 70,000 cans of the former and 10,000 cans of the latter per day of 12 hours.

Taking as the heat unit the boiler horsepower, which is equivalent to about 30 lb. of high-pressure steam per hour, or, more exactly, 33,479 B.t.u. per hr., and assuming the temperature elevation to be 132 deg., the useful heat added to the whole tomatoes amounts to 57.5 boiler hp. The pulp must not only be elevated in temperature but thickened by evaporation of some of its water. Assuming a reduction of 5:4, the boiler hp. necessary is 18.5, making a total of 76.

Of the useful heat to the whole tomatoes only 9 boiler hp. is added in the exhaust box, the remainder being added in the process kettle. The figures on the drawing enclosed in circles represent the waste heat either through exhaust steam, or hot water from drains, or radiation.

These heat quantities may seem excessive, but it should be remembered that they vary in each of the particulars very considerably in different plants. The distribution shown may be considered on the whole not unrepresentative.

A study of this example shows that there are two general methods of obtaining heat efficiency in the use of steam. First, by improvements in the construction and operation of heat-transfer apparatus, and second, by establishing a coördination of units so that what has ordinarily been considered as waste and irrevocable heat may be recovered to the fullest extent possible. These requirements do not exist independently. Let us then consider first the efficiency, or lack of efficiency, of the various steam-using units familiar in the canning factory, having special regard to the possibilities of eliminating steam wastes, and with all due respect to the paramount necessity of capacity.

BLANCHERS AND SCALDERS

Blanchers and scalders both make a heavy drain on the steam pressure. In their operation water and steam are led to a single chamber, circular or rectangular in cross-section, through which also the vegetables or fruit are fed. In blanchers

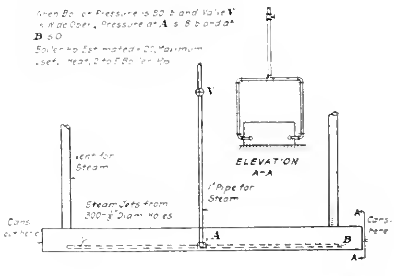

FIG. 2 HOME-MADE FORM OF EXHAUST BOX

the steam heats the water which is constantly overflowing, and excess steam is carried through a vent flue to the roof. Upon meeting the hot water, the raw material is washed free of its gummy coating, etc., which gradually contaminates the water and necessitates a continuous supply. The incoming fresh water requires more steam to maintain the temperature. Furthermore, steam must be added in sufficient amount to counteract the cooling effect of the entering food. From these considerations it becomes apparent that an exercise of judgment

is required to regulate the water and steam supply to the rate of the food material to secure the best economy with steam. The water should be fed in just fast enough to maintain the minimum degree of purity consistent with the requirements. Any greater amount of water necessitates more steam, the heat of which is wasted through the overflow. Any greater amount of steam than is necessary to maintain the temperature merely blows through the vent flue. Obviously, two or three times as much steam as is necessary may be consumed if regulation is neglected.

In the operation of tomato scalders a similar conclusion may be drawn. Here the steam and water do not mix, that is, intentionally, it being the purpose to have first the steam and then the cold water strike the raw material. Steam at 80 to 100 lb. pressure is supplied through a 2-in. pipe and passes through a series of perforated holes in pipes placed above and below a conveyor chain carrying the tomatoes. The bed of fruit is something like four to six inches thick, and it is expected that these steam jets will penetrate the mass and heat their outer skins in about ten seconds. Now, in the same chamber in which the steam is working, and just beyond the steam jets, are jets of cold water. There is no dividing partition, and the result is a splendid condenser effect. As the water must be kept cold, more of it than otherwise necessary is turned on to counteract this effect, thereby enhancing it. Provision is made through a vent flue so that if any steam escapes both water and tomatoes, it can go out through the roof.

Obviously, with the application of ingenuity and experiment the steam consumption of these machines might be materially lessened through radical structural changes without impairing effectiveness or capacity. On the other hand, and opposite to the case of bleachers, it is difficult to secure steam economy by nice regulation alone—for one reason because of the prejudice of operators.

Exhaust Boxes

Exhaust boxes are now to be considered. In the home-made form (see Fig. 2) these are long rectangular boxes made of four planks, open at the ends, and through which a conveyor

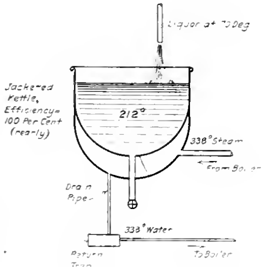

Fig. 3 Jacketed Kettle

chain passes bearing the filled but uncovered cans. Drilled pipes within the box are used as steam jets playing on the cans. At the ends of the box are flues, so that when the steam is fully turned on it will not pass into the packing room but out through the roof.

It is at once apparent that it is out of the question to obtain anything like a uniform temperature of the can contents in the small space of time that they are subjected to the steam, particularly if they are packed closely and contain little liquid. The heat consumed in the form of steam may be as much as anything between 20 and 30 boiler hp., making for a thermal efficiency of about 10 to 15 per cent. Where does the difference go? Through the roof.

The performance of the exhaust box as regards steam economy may be materially bettered by the careful regulation of the steam supply. From trials which the writer has made, involving temperature and pressure measurements, he has found that the steam can be cut down from full on to about one-half a turn of the stop valve in some cases without materially affecting the temperature elevation. That is, the heating effect is nearly as good when the steam merely trickles through

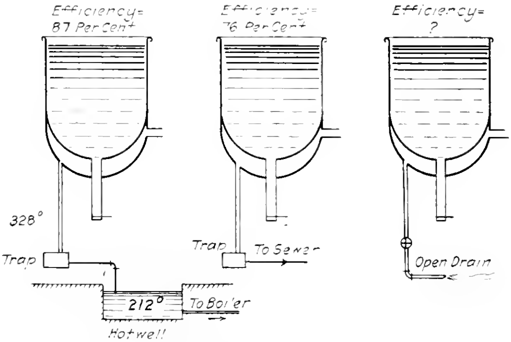

Fig. 4 Various Ways of Handling Steam in Connection with Jacketed Kettles

as when it pours through. To gain effectiveness, the time during which each can is subjected to the steam must be lengthened, and the greater the time, the greater will be the machine's efficiency. This fact is being recognized by the manufacturers of modern forms of exhaust box, which are so shaped that the length of the path through them is greatly increased, thereby increasing the time of heating (to 5 and 15 min.).

Much can be gained if the exhaust box is in part relieved of its effort by introducing whatever liquor goes with the solid part of the contents as hot as may be.

Jacketed Kettles

Turning now to a consideration of the various packing-house units used for concentrating liquid foods and food juices, which units may be termed generally "evaporators," it will be noted that there are many different forms and types. Perhaps the most elementary form, and in some ways the most interesting, is the jacketed kettle (see Fig. 3). It has a capacity of between 50 and 500 gal., and instead of having heat applied to it as an open flame, receives it from the steam jacket whence it gets its name. The jacket is tapped with one or more openings to receive the steam pipes, and another opening for the drain pipe to carry off the condensed steam.

The performance of these kettles is very interesting in many ways. In the first place, it may be observed that under approximately ideal conditions their thermal efficiency may be nearly 100 per cent, the only loss being from radiation of heat from the outside of the jacket. This assumes that the condensate from the jacket is returned to the boiler through a return trap which, however, is not always—or even often—used. Steam at 100 lb. gage pressure has a temperature of 338 deg., so if steam of this pressure is used in the jacket

of a kettle it will, after condensing in the jacket, emerge from the drain pipe as water at 338 deg. If this hot water is returned to the boiler by a return trap, none of its heat is lost (except that small amount due to radiation), and practically all of the heat given up by the steam goes to the useful purpose of evaporating water from food material.

There are, however, three other ways in which steam may be handled (see Fig. 4). First, the drain may be passed through an atmospheric trap, which necessitates that the water be reduced to below 212 deg. before it can be returned to the boiler. In this case the efficiency of the system is 87 per cent, and 13 per cent of the heat consumed is wasted. Practically the same thing may be accomplished if the drain pipe is without a trap but is supplied with a stop valve so regulated that only water will be discharged. Second, the kettle may be supplied with an atmospheric trap, or a stop valve in the drain pipe as just described, the discharge from which is *not* returned to the boiler. In this case, if feedwater at 70 deg. is used to make up the 212-deg. water which might have been used, the waste is 24 per cent and the efficiency only 76 per cent. Third, the kettle may be unprovided with a trap of any kind, and the valve in the drain pipe left so wide open as to let large quantities of steam escape as well as condensate. Here it is difficult to estimate the ensuing waste, but if one is to judge by the ascending clouds of steam, it must be enormous.

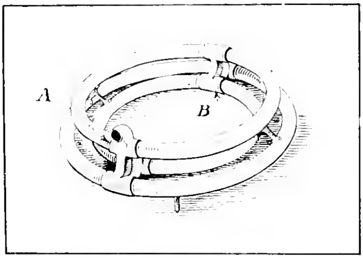

Fig. 5 Evaporator Coil of Modern Design

A jacketed kettle in full blast shows the most haphazard ebullition, and one would suppose that a much more effective rate of evaporation could be obtained if the circulation could be assisted. In spite of this, the fact is that this apparatus is a remarkably quick evaporator. Results that have come to the writer's attention show, with the use of 100-lb. steam, as high as 8.5 gal. or 70 lb. of liquid evaporated per square foot per hour after the mass has come to a boil. This corresponds to about 700 B.t.u. of heat transferred per hour per square foot per degree difference of temperature, a figure comparing very favorably with the best types of feedwater heaters and condensers, which class of steam-engineering apparatus the jacketed kettle most closely resembles as regards the matter of heat transfer.

Jacketed kettles, differently installed, show very different capacities for evaporation. The question then arises, What are the factors affecting the rate of evaporation? A study of this question shows that the total amount of water a kettle can evaporate per hour may be affected chiefly by the pressure of the steam in the jacket. The rate of heat transfer is directly proportional to the difference in temperature between the boiling material (about 212 deg.) and the substance supplying the heat, that is, the steam. Now, since the temperature of steam increases with its pressure, the high-pressure steam is more effective in rapidity. But if the steam pipes are too small, or if the kettle opening for steam is not large enough, there may be a considerable drop of pressure of the steam before it reaches the jacket, and a still further drop after it gets into the jacket. In consequence, and especially if the steam is initially wet, it falls in temperature and loses some of its effectiveness. Much can be done to improve capacity by using carefully calculated pipe sizes and by *introducing the steam into the jacket through two or more openings instead of only one*. A series of experiments with the purpose of learning the pressure within a steam jacket for different systems of piping would, it is felt, disclose facts of practical value in future design.

The capacity of a jacketed kettle may be much reduced by the cooking material caking to its sides. To avoid this condition, kettles are frequently equipped with mechanical stirrers which continuously wipe the heating surface, thus keeping it clean. This action also imparts a velocity to the boiling liquid at the heating surface which, presumably, affects the heat transfer, but just how much is not known. Similarly, the quantitative effect of high velocity of the steam in the jacket is unknown.

Coil Evaporators

The final limitation to capacity has to do with the area of the heating surface. The obvious step, then, is to add heating surface in order to increase capacity, and this has been done.

Coils offer such an attractive way of forming a compact heating surface, that they have come into favor in units which dispense entirely with the steam jacket. Any form of containing vessel may be used for the liquid to be concentrated, and the vessel may be made of any appropriate material. Jacketed kettles are commonly made of copper: the containing vessels for coil evaporators may be made of wood, thereby making a great saving of expense. Also, a wooden vessel with coils occupying a given floor space may contain vastly more heating surface than a jacketed kettle occupying the same floor space, and therefore have considerably greater capacity. In such a case the coil evaporator also loses less heat by radiation from the containing shell, but otherwise the heat efficiency of the coil may be just as good or as bad as that of jacketed kettles previously cited. The effectiveness of a single square foot of heating surface of the coil is, it is believed, possibly less than that of the jacket, particularly if the coil is not carefully designed. "Effectiveness" in this connection means the number of heat units that can be transferred per hour from the steam to the liquid contents. As mentioned before, the efficiency may be nearly 100 per cent in each case.

Fig. 5 shows a coil of modern design taking steam through the manifold at *A* and exhausting from drain *B*.

Evaporators depending upon coils or nests of tubes suffer two serious disadvantages: First, they are much more difficult to clean and to keep clean than are jacketed kettles. Mechanical wipers, as stirrers, are out of the question, and hand cleaning is awkward. Second, they are, with poor design, more apt to leak steam into the liquid to be evaporated than are jackets, whereby both heat and capacity are lost.

Vacuum Pans

In the writer's opinion, a type of evaporator which will eventually enter the canning factory is the vacuum pan, Fig. 6. The advantage which it possesses is that it can use exhaust steam efficiently, and, when live steam is employed, the pan may be so designed as to take only half or less than half the

steam required by apparatus which boils at atmospheric pressure.

The subject of vacuum pans is too large a one to enter upon here, there being many different designs and principles involved. It may be mentioned, however, that the whole subject is replete with unsolved problems which give much opportunity for successful research work.

All of the evaporators cited may meet a check in their capacity when certain products are handled, through the thickening and foaming of these products. To avoid boiling over, foaming necessitates a cutting down of the rate of evaporation. Similarly with thickening—the resulting increased viscosity of the mass causes a spattering dangerous to operators and wasteful of material. In such cases the initial rate of evaporation must be lessened toward the end of the process. The remedy is evaporators with high sides to prevent boiling over, and stirrers to prevent caking.

TABLE 1 PERFORMANCE OF EVAPORATORS

Type of evaporator	Evaporation, lb. per sq. ft. per hr.	B.t.u. transferred per sq. ft. per hr. per deg. fahr. difference in temperature
Jacketed kettle with 100 lb. steam pressure, by test	66 6	660
Jacketed kettle with 50 lb. steam pressure, assuming the same B.t.u. rate of transfer	45 0	
Jacketed kettle with 25 lb. steam pressure	29 0	
Shell evaporator, with paddles, 50 lb. steam pressure, by test	41 5	625
Coils, 100 lb. steam pressure, by test	60 0	628
Vacuum pan, single effect, 25 lb. steam pressure, on tomato paste; average, by test	40 0	313
Vacuum pan, maximum, 100 lb. steam pressure	105 0	600
Vacuum pan, with 10 lb. steam pressure, single effect, and 26 in. vacuum	64.5	600

Another item which should be carefully calculated for individual evaporators as well as a number of them together, is the drainage of the spaces supplying steam. It is very easily possible to food these spaces with water, either through too small a pipe size for the drain from the jacket or coil, or by having one unit flood another, or by a badly designed unit of which coils are a conspicuous example.

Comparative Performance of Evaporators

In Table 1 the first three lines show the effect of using steam of a lower pressure than 100 lb., the rate of evaporation in lb. per sq. ft. per hour rapidly falling off with the lower-pressure steam. The low result of the shell evaporator may be explained possibly by the effect of the design, in that the heating surface was so arranged that part of it could be flooded during operation. It is seen from the table that the best results were secured with the jacketed kettle. This fact is very much influenced by the steam connections, in that if only one is used, the rate of evaporation may be only half that obtained when two generous steam openings are used.

Table 2 is intended to show the real advantage of coils. The figures presented are obtained from a number of kettles and coils in actual operation. It is seen that as the capacity of the kettle increases the heating surface per unit of contents decreases, which is not true of the coil, the reason being that the jacket surface of the kettle increases with the square of its linear dimension, whereas the volume increases as the cube.

Process Kettles

The last item to be considered is the process kettle. In one way this is perhaps the most important of all, since the success of the pack depends upon the process kettle. Its whole function is to raise the temperature of the contents of the cans to that necessary for sterilization. Fig. 7 is a diagrammatic representation of a process kettle.

There are four methods in use in the operation of these units: First, the cans are placed in the process kettle, which is previously empty; the kettle is then closed and steam turned on so that a pressure of between 5 and 15 lb. gage is secured. Second, this same process may be used, except that the kettle

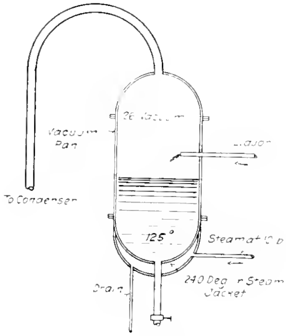

Fig. 6 Vacuum Pan

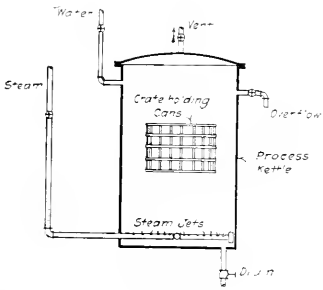

Fig. 7 Diagrammatic Representation of a Process Kettle

is previously filled with hot water and the cans are subjected to a water bath under pressure at a correspondingly high temperature. Third, the cans may be placed in a closed process kettle and subjected to a pressure very slightly greater than atmosphere, say, 1 lb. gage, there being no water in the kettle. Fourth, the process may be under atmospheric pressure but in a water bath with the lid of the kettle raised. These processes may be referred to as dry and wet, respectively, and closed and open.

In the open-bath process it is a custom of operators to maintain a violent boil of the bath so as to secure a circulation through all the interstices between the cans, which practice results in large volumes of steam being emitted into the packing room. In the closed process it is the custom to vent the valve on top of the kettle. When the process is wet, it seems that the object is twofold: first, to secure a circulation through the

interstices, and second, because it is easier to maintain a uniform temperature with the steam flowing through rapidly with this vent valve considerably open than to secure this uniform temperature with only a small vent.

Now, besides raising the temperatures of the cans in the dry process, heat has to be furnished to the kettle in the following directions, all of which is wasted:

1 To raise temperature of the metal of crates and kettle
2 To vent the kettle allowing air to escape, or to establish a circulation through the cans
3 Condensed steam drained from kettle
4 Radiation of heat from the outside surface of the kettle.

To these items, must be added, when the wet process is used, the heat necessary to raise the temperature of a mass of water

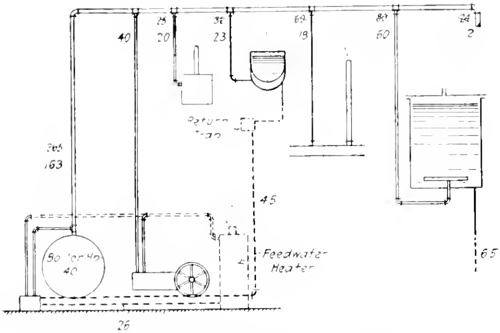

FIG. 8 POSSIBILITIES OF IMPROVING PERFORMANCE OF THE PLANT OF FIG. 1

as well as that of the cans. Table 3 gives some quantitative values, obtained in part by test, but for the most part by calculation upon the assumption of reasonably good conditions in each item. In this connection it should be remembered that radiation, venting and overflow wastes may each vary widely with different operators and units.

Comparing the boiler hp. required for the different systems it is noticed that the closed wet process takes about three times as much steam as the dry at 216 deg. On the other hand, the former is capable of twice the capacity of the latter, so that the proportion of steam per can used is as 3 is to 2.

Efforts have been made to increase the capacity of process kettles by agitating the cans during cooking, machines for this purpose being styled "continuous cookers."

There seems to be ample field for enlightenment by experiment in the case of process kettles. Among the questions to be answered are: What are the times necessary to elevate the temperature of the center of a can under the open or closed systems, and how much difference is made by circulating water instead of steam upon the time? What effect has venting the kettle different amounts? What effect has agitating the cans? If such venting of the kettles has any favorable effect, how may the steam thus lost be recovered? How does the temperature of the cans at various parts of the kettle vary? Of what value are automatic regulators to steam economy?

POSSIBILITIES OF IMPROVING PERFORMANCE OF PLANT

Referring to Fig. 8, the possibilities of bettering the performance indicated by Fig 1 are shown. The consumption of the scalder is reduced from 25 to 20 boiler hp. by careful supervision of its performance. The efficiency of the jacketed kettle is improved by means of the return trap which passes back to the boiler $4\frac{1}{2}$ boiler hp., thereby eliminating all possibility of waste in steam through the drain. The exhaust box is increased in efficiency to 50 per cent, and very probably much better than this can be secured with the more modern forms of exhaust box, the loss then largely being due to radiation. By using the dry process at 216 deg. the process kettle loses heat only to radiation in amount equal to about 5 boiler hp. and through condensate from the drain equal to about $6\frac{1}{2}$ boiler hp., the loss through the vent with automatic regulation being negligible. It is questionable how the $6\frac{1}{2}$ boiler

hp. escaping from the drain may be utilized. It might be returned to the boiler as feed if provision were made to eliminate impurities. An exhaust-steam feedwater heater is added, by means of which 26 boiler hp. is recovered, but as the exhaust steam is in excess of the requirements for preheating the feedwater, some of that available from the engine is lost through the vent. It is very possible that this excess of steam should be recovered in one of the steam-using units; for example, if a process kettle were designed with sufficiently large steam pipes and openings, exhaust steam could be used in it, or this steam could be used in a vacuum pan. There are a number of such possibilities.

GENERAL CONSIDERATIONS

Having now taken up in more or less detail the various familiar steam-using units in the canning factory, the writer would conclude with a few remarks of general application. Economy in steam means three things: increasing efficiency of units, eliminating all avoidable wastes, and utilizing all other wastes of heat as by-products. The first two can only be accomplished through measurement—it is necessary to know *how much steam* is used and wasted. The packing house should be properly equipped with measuring instruments for this purpose. The familiar and little appreciated pressure gage is almost a stranger in the packing house, and yet a judicious use of this instrument will disclose much valuable information as to how steam is being used or abused. To find

out how low the steam pressure is on some units whose inefficiency or lack of capacity has been ascribed to other causes and inspired futile remedies, will open the eyes of the superintendent. Next, when we eliminate wastes, we must eliminate *all wastes*, and not tolerate any just because we have been accustomed to seeing them and know that they are difficult to avoid. Wherever steam shows in the atmosphere it represents a waste, whether the steam comes from the jacket of a kettle, the vent of a process retort, the flue from an exhaust box or heater or scalder, or from any cause whatsoever. We have no right to shoot steam into the atmosphere, even if it is exhaust steam. We have no right to *radiate* heat to the atmosphere which might be saved by non-heat-conducting protection, and such wastes, it is necessary to say, are wantonly committed in the packing house. No steam-using units the writer has seen in such houses make the slightest provision against loss of heat by radiation. This is not only a waste of coal but a waste of human energy, since the operators cannot work efficiently in the torrid heat usually prevailing and aggravated by radiation from steam-using units. The packer objects on the ground of expense, but he should remember that each square foot of surface with steam behind it radiates to the atmosphere in ten hours an amount of heat requiring the burning of 1 lb. of present-day coal, and then, upon calculating what this aggregates to, will he realize that it is not a question of the expense of installing pipe coverings and other similar devices, but the expense of not doing so.

Finally, the question of how to utilize by-product heat requires careful study. In each factory the problem may be different, and in each it may be a separate case of proportioning the units to fit into each other. Feedwater heaters, traps, low-pressure heaters—all should be considered. Even the water used for cooling the cans, which carries away all of the useful heat transmitted, as previously defined, may be made to render up some of the heat it has removed.

AN INVESTIGATION OF THE FUEL PROBLEM IN THE MIDDLE WEST

By A. A. POTTER, MANHATTAN, KAN.

Member of the Society

The cost of producing power has increased in the various power plants of the Middle West from 15 to 60 per cent during the winter of 1917-1918. The Detroit Edison Company report that for 1917 the total operating expenses were 35 to 40 per cent greater than in 1916. The Quincy (Ill.) Gas, Electric and Heating Company, states that the increase has been 40 per cent. The cost of production in the Sioux City (Iowa) Gas and Electric Company has been increased by 60 per cent.

The increased cost of producing power has been due to:

a The increase cost of fuel

b The necessity of burning fuels of different grades with equipment suitable for one particular grade

c The greater amount of ash and other non-combustible matter

d The increased cost of labor and the poorer quality of labor available

e The increased cost of repairs, supplies and new equipment.

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here presented in abstract form, and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

Increase in Cost of Fuel

The Commonwealth Edison Company, of Chicago, Ill., report the cost of coal per ton, for January 1916, 1917 and 1918 as \$1.78, \$2.72 and \$3.14, respectively. A large power plant in Indiana paid for coal an average of \$3.60 per ton during the winter of 1917-1918, as compared with \$1.66 during the winter of 1915-1916. A large power plant in Omaha, Neb., paid for fuel during the winter of 1917-1918 at an average rate of \$4.45 per ton as compared with \$2.85 in normal times. In Kansas power plants the cost of fuel has increased about 70 per cent as compared with normal years. The Jackson Light and Power Company, of Jackson, Miss., report an increase in the price of coal from \$2.12 to \$4.48.

Grades of Fuel Used

The majority of the power plants in the Middle West burned any grade of fuel they could secure and were forced in most cases to go to the open market for their supplies. Plants using bituminous screenings, slack and mill run were forced to burn mine run and even screened nut and lump coal. One large power company of Indiana, which ordinarily uses fourth-vein Indiana screenings, used during the winter of 1917-1918 only 40 per cent screenings and 60 per cent mine-run and lump coal. The larger sizes were purchased, partly on account of the difficulty experienced in securing any definite or uniform grade. The increased attention to coal storage was also responsible for the use of the larger sizes, as fine coal is more liable to danger from fire on account of spontaneous combustion. The use of lump coal necessitated in some plants additional expenditures for crushing before the fuel could be used with certain types of stokers.

Several plants in Illinois used coke breeze. Several plants in northern Louisiana and in the other southern parts of the Central West used wood and wood waste to a limited extent. In North Dakota greater use was made of lignite slack.

Some efforts were made in several states to use fuel oil in place of coal, but it was found more expensive than coal and in the majority of cases, more difficult to secure on account of the shortage of tank cars. In Kansas coal and oil were equally difficult to secure, except in the southeastern portion of the state where oil and natural gas are used exclusively in power plants. In Oklahoma natural gas is used ordinarily in the power plants at Oklahoma City, El Reno, Muskogee, Enid, Tulsa and other cities and towns. The power plants located near natural-gas fields experienced a great shortage of gas during the past winter and had to use fuel oil. In some plants this change meant an increase in operating costs of several hundred per cent. In the largest portion of Texas, lignite and bituminous slack were cheaper for power-plant use than fuel oil. Substitutions for coal were found impractical in most cases.

Suggestions have been made by power-plant engineers that the Fuel Administration should segregate the supplies from the different mines in such a manner that individual plants would get their supply of uniform grade. Where several hundred tons of coal of different grades are mixed and stored in overhead bunkers, it is impossible for stoker operators to adjust their firing conditions as to feed and draft to suit the fuel served. With uniform grades of fuel, operating conditions can be adjusted for best efficiency.

In several cases the fuel scarcity and high cost resulted in the greater use of coal near the producing point, but in most cases it was a question of keeping the plants going, irrespective of the price of fuel.

The fuel situation in the power plants of Iowa, Kansas, South Dakota, Texas and Oklahoma was not as serious as in the more populous states of the Middle West. Many of the smaller power plants either had considerable fuel in storage or reduced their load. The majority of the plants in the Middle West were affected more by the quality than by the scarcity of fuel.

Impurities in Coal

One large plant in Illinois reports that the coal used during the winter of 1917-1918 contained 16 per cent ash as compared with 9 per cent in former years. Several of the power plants in Minnesota reported 25 to 35 per cent ash and slate in coal during the winter of 1917-1918. The plants of Louisiana had to use coal which contained in many cases 30 per cent ash, as compared with an ash content of 5 to 10 per cent in former years. An engineer in a large power plant at St. Louis, Mo., stated that the cost of producing power in that particular plant has increased 51 per cent, 40 per cent being due to the increased cost of fuel and 11 per cent to the increased non-combustible impurities. In general, the ash content in the fuel used during 1917-1918 was at least 5 per cent greater than in former years on account of the faulty methods at the mines. Power-plant engineers feel that the high ash content is greatly responsible for the fuel shortage and for the increased operating costs. In ordinary times fuel containing more than 30 per cent ash would be condemned for use in boiler-room furnaces.

Cost of Labor

The cost of common labor has increased in the various parts of the Middle West from 25 to 100 per cent. Operators and firemen in power plants are receiving more pay, but in rare cases is the increase as great as 25 per cent when compared with normal times. The cost of manufacturing power has probably been more affected by the poor quality of power-plant operators and labor available than by the increased cost of such labor.

Effect Upon Isolated Plants

In a few cases the increased operating expenses and the scarcity of fuel had a distinct tendency to eliminate isolated plants and to transfer the load to central stations. This was especially true where the rates of central stations are maintained constant by law. The large central stations in most cases, however, were not too vigorously soliciting business on account of the increased costs of fuel, labor, material, and new equipment. Some power-plant managers insist on a coal-and-labor-cost clause in connection with contracts for power. Public utilities complain about the difficulties which they are experiencing in financing improvements.

Many power companies are more concerned on account of insufficient plant capacity than because of the increased cost of fuel. Improvements and extensions in equipment are affected by the high cost of money, by the high prices of materials and equipment and by the difficulty of securing deliveries of materials and equipment purchased. A manager of a large central station in Indiana states that they are three years behind in expansion, development and replacement.

Efforts for Better Fuel Economy

The fuel situation during the past winter has resulted in greater efforts for fuel economy. This is particularly noticeable in the small power plants of the less populous portions of the Middle West. The high cost of new power-plant equipment has some tendency to delay improvements, but it is remarkable to see power plants in towns of 2000 inhabitants, or even smaller, discarding an inefficient old steam prime mover and paying at the rate of $200 per kilowatt capacity for new units, in order to produce fuel economy. The use of draft gages and of other measuring instruments is increasing in the boiler room, greater attention is given to the utilization of exhaust steam in non-condensing plants, more pipe covering is used, greater attention is being given to boiler settings and furnaces, heating surfaces are kept cleaner, and definite efforts are being exerted for the more economical utilization of fuel in the power plant.

Work of the Fuel Administrators

The work of the Fuel Administration Boards of Iowa, of Louisiana and of Illinois, is particularly creditable. The fuel-conservation campaign in Iowa consists of:

a Inspection of boiler rooms and heating plants, with recommendations as to improvement in equipment and operation, and instruction of firemen in proper firing methods

b Talks to groups of engineers and firemen on combustion and firing methods

c Talks to general audiences on the economical use of fuel in the home, and on firing house furnaces; and

d Dissemination of information on burning soft coal in house furnaces. Inspections of house-heating plants were made to a very limited extent.

Iowa State College at Ames furnished seven engineers to carry on this work, each of whom spent during the past winter from two to twelve weeks making inspections and giving talks and demonstrations. Their services were available to any city or town in the state without charge except for traveling and hotel expenses.

Prof. D. C. Faber of the Iowa State College, who is the consulting engineer for the Federal Fuel Administration for Iowa, gives the following in his recent report:

> Thirty-four cities and towns asked for this service, including practically all of the larger cities of the state. 1354 plants were inspected, and 80 talks given to a total of 7330 people.
>
> The boiler-plant inspections were made to point out defects in equipment and operation, and to give the firemen proper instructions in firing methods. The inspectors were equipped with draft gages, CO_2 recorders, and thermometers for measuring flue-gas temperatures. The inspections varied from casual inspections to complete investigations of combustion conditions, as circumstances required. It is not possible to enumerate the defects found by the inspectors, but a few of the commonly found faults were: Leaky boiler settings; uncovered steam pipes; failure to remove soot at frequent intervals; failure to regulate fire by use of damper in uptake; fire too thick; and firing too large a quantity of coal at one time.
>
> In the talks to engineers and firemen, combustion, hand firing methods and boiler-room losses were explained. These talks were accompanied by lantern slides, charts and demonstrations.

In Louisiana an extensive campaign for fuel conservation has been undertaken under Leo S. Weil, advisory engineer for the Federal Fuel Administration for Louisiana. Mr. Weil gave a complete description of his work in *Power*, Vol. 47, No. 5. Efforts were made to have other fuels substituted for coal, but these were found impractical in most cases. The fuel consumption was decreased by shutting down some of the ice plants which operated during the winter at about one-third of their normal capacity, and the remainder of the ice plants were run at nearly normal capacity, supplying ice to those which were shut down. The attention of power-plant owners

and of operators was called to the necessity of reducing waste of coal and to the desirability of coöperation on the part of both owners and operators. Suggestions concerning reduction of coal waste were sent out to power-plant operators. Mr. Weil reports very gratifying results due to the above efforts.

The Conservation Committee of the Fuel Administration of Illinois, with Prof. H. H. Stoek of the University of Illinois as chairman, is carrying on very constructive work among the power plants of that state in the interest of fuel economy. Those in charge of power plants are being urged to go over their equipment and to make necessary improvements. The Conservation Committee has also the coöperation of the factory inspectors of Illinois, who are bringing the matter of economy to the attention of the owners and operators of plants inspected by them.

Conclusions

The power plants of the Middle West are convinced that future emergencies can be averted by more adequate fuel storage, by greater attention to fuel economy, and by the more careful regulation on the part of the Government of the quality of fuel leaving the mines and of the fuel-transportation facilities.

Several state fuel administrators are expecting to start campaigns urging the early purchase of fuel for domestic use, and greater storage of coal by power plants during the summer. The larger power plants are expecting to store greater amounts of coal than usual. Some plants expect to provide storage capacity sufficient for 30 days; many of the smaller plants expect to put in larger storage capacity. Considerable difficulty is being experienced in storing many of the middle-western bituminous coals on account of spontaneous combustion. Storage under water will be used to a considerable extent. The Nebraska Power Company, of Omaha, which uses 250 to 300 tons of coal per day, constructed two subaqueous coal storage pits of a total capacity of 8000 tons and at a cost of about $120,000. The Commonwealth Edison Company, of Chicago, devotes about 100 acres of high-priced land to coal storage. On this land are nearly ten miles of railroad tracks and other improvements, in addition to locomotives and locomotive cranes. Mr. W. L. Abbott, chief operating engineer of the Commonwealth Edison Company, states that in addition to the above investment in storage facilities there is the great expense of storing upward of a million dollars' worth of coal and carrying much of it year after year, but that the outlay and expense are warrantable from a business point of view.

In the case of power plants using natural gas, a gas-storage-tank capacity sufficient for a 10-day period is considered practical. Such a storage capacity will take care of gas shortage during extremely cold weather.

More attention will be paid in the future to the proper furnace design for high-volatile bituminous coals. The combustion chambers of the furnaces in the majority of the smaller power plants are not large enough for the air to mix with the gases given off from the fuel bed and before such gases come in contact with the comparatively cool heating surfaces of the boiler.

Some attention should be given to the use of peat in certain parts of Michigan, Minnesota and Wisconsin for domestic use and possibly also for power generation. With the increasing scarcity and higher cost of coal and oil, low-grade fuels must be given greater consideration in connection with the generation of power.

The fuel administrators of the various states should be encouraged to secure engineering assistance, particularly in connection with the campaigns for economy in the smaller power plants. Much fuel can be saved if the operators of the small power plants can be carefully instructed with reference to the overhauling of equipment, the avoidance of air infiltration through settings, proper firing methods, correct thickness of fuel bed and other operating details which lead to the economical utilization of fuel. The institution of campaigns for fuel conservation, such as have been undertaken in Louisiana and in Iowa, will result in greater fuel economy. Such campaigns are absolutely necessary in the less populous sections of the Middle West, where the majority of the power plants are small and are operated by poorly trained attendants.

E. G. Bailey, Mem.Am.Soc.M.E., advocated recently that the price of coal be regulated by the Government according to the quality of the fuel produced, in order to give the coal operator a real incentive to clean his coal as he should. He states that—

> The base price for standard quality of coal should be established by the Government as at present, with possibly different base prices and different quality standards for the several districts, taking into account the character of coal, height of seam and other mining conditions; but the main thing to strive for is to obtain the highest quality of coal and the most concentrated form of heat units in order to tide us over the coming year, which is going to be much more critical than that just past, unless some radical step is taken to apply a remedy for the basic cause of the present situation.

The United States Fuel Administration has announced that, beginning March 11, 1918, an inspection system will be effective to insure improvement in the quality of bituminous coal leaving the mines. Coal containing a high percentage of impurities will be condemned or will be sold at 50 cents per ton less than the fixed Government price for that coal. There is no definite system recommended upon which the inspector may base his conclusions as to the quality of the coal. In ordinary times the operators are forced by competition to produce a low-ash coal. It is possible that the Government may be able to improve the quality of the coal leaving the mines by enlisting all mine officials and employees in some form of industrial army for coal production. Otherwise, some definite plan of fixing prices for definite quality standards should be worked out.

A detailed study of coal-car movements in the Middle West during the past four years discloses the fact that the average time required to move cars is extremely long. In most cases cars carrying coal will average less than 20 miles per day. When to this time is added the time required for empty cars to return to the mines, it is evident that the coal tonnage handled per car per year is very limited and very much smaller than reasonably efficient operation should produce. This delay is due partly to the practice by railroads of throwing cars on sidings and into yards with unnecessary switching, instead of delivering them to their destination in one or two hauls. Pooling of engines, cars and routes can be made to substantially relieve this situation. Another relief can come by so routing coal as to avoid, as far as possible, the congested terminals at the larger cities.

To avoid the recurrence of the conditions of last winter, the power plant men will have to coöperate with the Government by providing adequate coal-storage facilities, by unloading fuel without delay after it reaches its destination, and by giving careful attention to power-plant economy. The Government will have to insist upon reasonable cleanliness of coal leaving the mines, and should give more attention to the improvement in the railroad equipment and in the methods of transporting coal from the mines to the consumer.

THE PUBLIC INTEREST AS THE BED ROCK OF PROFESSIONAL PRACTICE

A Discussion of the Objects of Engineering Societies and Their Obligations to the Public

By MORRIS LLEWELLYN COOKE, PHILADELPHIA, PA.

Member of the Society

THE members of our Society individually are doing everything in their power to help to win the war. To this end we dedicate personal convenience, financial interest, and life itself. A study of the program of this and other recent meetings of the Society indicates that collectively our aim is the same. One has but to read the technical engineering journals to realize that perhaps no other profession is so profoundly affecting the actual conduct and progress of the war as is our own. Without doubt, engineers as a class are making every possible effort, and at every possible sacrifice, to make Liberty triumph in the present struggle. In other words, there is in our conduct the clearest recognition of the paramount obligation which we owe to the Nation, and, in the last analysis, to humanity. In view of this attitude taken spontaneously in time of war, it is curious to note that our public responsibilities are almost ignored in the codes of ethics of our organized associations of engineers. Drafted as they have been to control our conduct in times of peace, these canons of professional practice carry almost no reference to the public interest as a controlling, much less as a paramount, obligation of the individual engineer, of engineering societies, and of the profession as a whole.

This is a time of stock taking and of a critical examination of the orders under which society and its constituent elements are operated. Within the church, among labor organizations, in government, in the educational field, and in the professions,—everywhere, in fact,—we find the same searching inquiry as to aims and methods. Hence, there can be no better time for a review of the codes of ethics designed to regulate the professional practice of engineers. The object of this paper is to determine what has been, and apparently continues to be, the attitude of engineering organizations toward society as expressed in our rules of conduct. It is further sought to develop the engineer's concept of his public relationships and responsibilities as contrasted with such relatively minor obligations as those to the profession of engineering, to a client, to fellow-engineers, and to himself.

The oldest, the largest and perhaps the most representative society of American engineers, the American Society of Civil Engineers, for instance, makes absolutely no mention in its Code of Ethics of any such public responsibility. The Code in full is as follows:

> It shall be considered unprofessional and inconsistent with honorable and dignified bearing for any member of the American Society of Civil Engineers:
>
> To act for his clients in professional matters otherwise than as a faithful agent or trustee, or to accept any remuneration other than his stated charges for services rendered his clients.
>
> To attempt to injure falsely or maliciously, directly or indirectly, the professional reputation, prospects, or business, of another Engineer. To attempt to supplant another Engineer after definite steps have been taken toward his employment. To compete with another Engineer for employment on the basis of professional charges, by reducing his usual charges and in this manner attempting to underbid after being informed of the charges named by another. To review the work of another Engineer for the same client, except with the knowledge or consent of such Engineer, or unless the connection of such Engineer with the work has been terminated.
>
> To advertise in self-laudatory language, or in any other manner derogatory to the dignity of the profession.

The first of these three sections refers exclusively to the engineer's relationship to the client, the second to his relationship to fellow-engineers, and the last simply deprecates advertising.

The code of the A. S. M. E. contains a section devoted to The Engineer's Relation to the Public, but it includes no recognition of the fundamental character of the obligation of the engineer to the public. Even the engineer's responsibility "to extend the general knowledge of engineering" is quite incidental. The major import of these injunctions has to do with a negative phase of the subject, i. e., the holding back from the public of inaccurate information or of too narrow statements with regard to engineering subjects. The really significant sentence in our code reads:

> The Engineer should consider the protection of a client's or employer's interests *his first obligation* [italics mine], and therefore should avoid every act contrary to this duty.

This sentence is fairly typical of what appears to be the keynote not only of this, but of every engineering code. These codes have apparently been drawn to hold up a high standard of personal integrity in relations with the client and to protect one engineer against another.

The omission of any reference to the public interest in the codes of professional practice of engineering organizations would not be so noticeable were it not for the fact that other associations of professional men have been at very considerable pains not only to express the obligation, but to insist on its paramount importance, and to phrase it in terms of lofty idealism.

The architects, whose work in many respects is quite comparable to that of the engineer, have been emphatic and successful in their efforts to govern their professional conduct along ethical lines. They have further made the effort to stress the public character of the profession, and to reward those who have made distinct contributions in the public service.

Perhaps the most conclusive statement in this matter is that which appears in the Code of the American Bar Association under the head, The Lawyer's Duty in Its Last Analysis:

> No client, corporate or individual, however powerful, nor any cause, civil or political, however important, is entitled to receive, nor should any lawyer render, any service or advice involving disloyalty to the law whose ministers we are, or disrespect of the judicial office, which we are bound to uphold, or corruption of any person or persons exercising a public office or private trust, or deception or betrayal of the public. When rendering any such improper service or advice, the lawyer invites and merits stern and just condemnation. Correspondingly, he advances the honor of his profession and the best interests of his client when he renders service or gives advice tending to impress upon the client and his undertaking exact compliance with the strictest principles of moral law. He must also observe and advise his client to observe the statute law, though until a statute shall have been construed and interpreted by competent adjudication, he is free and is entitled to advise as to its validity and as to what he conscientiously believes to be its just meaning and extent. But above all, a lawyer will find his highest honor in a deserved reputation for fidelity to private trust and to public duty, as an honest man and as a patriotic and loyal citizen.

Engineers need not be told that an axiom is undebatable. Surely no one will hold that the public interest is not funda-

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

mental to all professional ethics and practices. It is not even necessary to vote on the proposition. The simple enunciation of the statement makes it so obvious that further action is in a way unnecessary. On the other hand, one must necessarily question codes of ethics and canons of professional practice which have been drafted without the clearest possible recognition of the fact that such rules and regulations must be interpreted in the light of public interest.

In much of the vital engineering of the time the determinations are inextricably interwoven with questions of public policy. In fact, enlightened public engineering is in many directions the insistent need of the hour. If the established engineering agencies fail to respond both efficiently and disinterestedly to this call for service, others will inevitably be created more in the spirit of our great time.

Practically all the questions affecting professional practice among engineers that have been raised during the last few years would have settled themselves had this one standard of the public interest been held to be fully operative while at the same time the interest of the profession as a whole, the relations of the engineer to his client and those of one engineer to another engineer, were being safeguarded as far as consistent with the public interest.

We frequently hear it said both by engineers and by laymen that this is the day of the engineer, or rather that the day is just dawning when society must become increasingly dependent upon engineering. Can this day really arrive so long as the rules and regulations for our professional conduct are so largely taken up with rather crude and in many cases debatable injunctions, which have more to do with what might be called "keeping the peace" than with our immeasurably more important task of providing such an enlightened leadership in the present as will make our dreams of the future come true?

My own feeling is that every code now in use by engineers in this country and abroad should be entirely rewritten on much broader lines and in a more inspiring key. It is useless to undertake such revision unless we have determined that we shall open every such code with the clearest possible enunciation of the principle that no considerations of professional or other special interest shall weigh for one moment against the interests of the nations and of humanity itself.

STRESSES IN MACHINES WHEN STARTING OR STOPPING

Method for Their Determination, Taking Account of Inertia and Elasticity

By F. HYMANS, NEW YORK, N. Y.

Member of the Society

A CYCLE of operation of a machine can be divided in three more or less distinct periods, namely, the start, the run at constant speed, and the stop.

The calculation of machine parts follows at present one of two methods. The first assumes a state of equilibrium, which permits the application of the known processes of statics to determine the forces acting on each machine part. The state of equilibrium, however, exists only when the machine runs at constant speed or is at rest.

In the second method all of the machine parts are considered to be rigid. The calculations are based on the external forces as they exist during stop or start, from which the forces acting on each machine part are determined by means of the dynamics of rigid bodies.

Neither of these methods leads to even approximately correct results. The first may be dismissed altogether, since no consideration whatsoever is given to the quite different phenomena occurring at start or stop. In the second such a consideration is attempted, but is based on entirely wrong premises. For, if correct, the forces acting on the machine parts merely depend on their inertia and on the magnitude of the external forces. From experience, however, it is known that the forces acting on a machine part do not only depend on the above

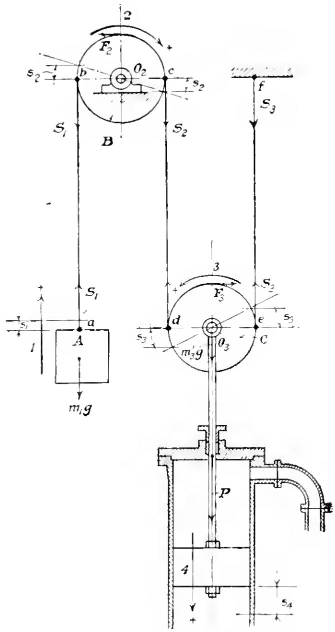

Fig. 1 Diagram of Hydraulic Machine

two factors, but, for example, also on the *nature* of the external forces. A feeble periodic force of the proper frequency, for instance, may cause the breakdown of a machine where a constant force of several hundred times its magnitude would be easily withstood. It is plain, therefore, that this method neglects the consideration of some property through which in the resulting formulæ the influence of the nature of the external forces vanishes. This property is the elasticity of the machine parts.

It is the object of this paper to present a method whereby the forces acting on the machine parts during start or stop may be determined with a degree of accuracy more than sufficient for technical purposes. While the method is explained in sufficiently general terms for ready application to any machine, it is more specifically applied to the determination of the motion and rope tensions during the starting of the hydraulic machine shown diagrammatically in Fig. 1.

As the figure shows, the machine consists of a vertical cylinder with a piston, adapted to lift the load A through the in-

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

termediary of a piston rod, a traveling sheave C, a stationary sheave B, and the ropes ab, cd and ef. The force P, acting on the piston and causing the motion of the machine, will be called the motive force, in distinction to all other external forces, such as the weight of load and machine parts, and the frictional forces.

According to the foregoing, it is necessary to consider not only the inertia of the machine parts, but also their elasticity. Strictly speaking, all of the machine parts are elastic. Fortunately, however, there are always a few which have elasticity to such a predominating degree that other parts in comparison with them may be considered to be rigid. Thus any machine may be approximated by a system of parts, of which some have elasticity and others inertia only.

In the machine of Fig. 1, for example, it is at once evident

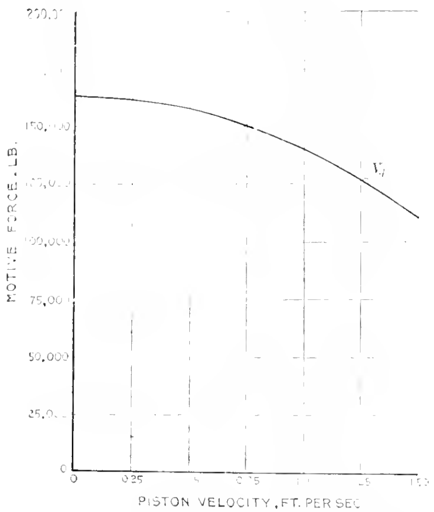

FIG. 2 MOTOR CHARACTERISTICS (MOTIVE FORCE AND PISTON VELOCITY)

that the ropes ab, cd and ef will be considered as the only elastic members. Their mass is very small and may be neglected. The remainder of the machine parts, that is, the load A, sheaves B and C, the piston and piston rod, will be considered rigid.

The author's method is based on the general energy equation of the machine, from which he derives all of the equations required in the further calculations. According to dynamics, this equation states that the gain in kinetic energy plus the gain in potential energy equals the work done by the external forces.

To derive the energy equation of the machine certain displacements are assigned to the rigid machine parts, such as s_1, the linear displacement of the load A; s_2 and s_3, the circumferential displacements of points b and c of sheave B, and of points e and d of sheave C; and s_4, the linear displacement of the piston and the parts rigidly connected thereto. Since the velocity of the rigid parts is the first time derivative of their displacements, it is quite simple to derive for each of them the expression of the kinetic energy. The kinetic energy of the machine then is the sum of the kinetic energies of its constituent parts.

The elastic machine parts—here the ropes ab, cd and ef—are the seat of the potential energy of the machine. By virtue of their elasticity they are capable of sustaining deformations, and so long as they are stressed below the elastic limit there is stored in them an amount of energy equal to the energy that produced the deformation. This energy is called the potential energy.

Considering now the rope ab, it is evident that if the end b has moved through the distance s_2, and the end a through the distance s_1, the rope has suffered an elongation equal to $s_2 - s_1$. Knowing further the elongation which a tension of 1 lb. will cause in the rope, it is merely necessary to apply the well-known laws of statics to determine the energy necessary to produce the deformation $s_2 - s_1$.

This process is also applied to ropes cd and ef, and the potential energy of the machine will be the sum of the potential energies of its constituent elastic parts. The derivation of the work done by the external forces needs hardly any elucidation.

From the foregoing it will be evident that, after having determined which of the parts shall be considered elastic and which rigid, the derivation of the general energy equation of the machine will not present any considerable difficulties. It will also be quite clear that the machine parts to be considered rigid are those wherein either the stress or the deformation, or both, are so small that the amount of potential energy stored in them is negligible. Further operation with the general energy equation is facilitated by the resolution of the absolute motion into two components, which the author calls rigid and relative motions. This is based on the following considerations.

The tension in rope ab (see Fig. 1) changes from instant to instant during the start of the machine. If the tension decreases, the rope contracts, causing points a and b to approach each other. Vice versa, if the tension increases they recede from each other. These varying elongations, however, are merely varying increments in the free length of the rope ab. It follows at once that the motion of points a and b, that is, the motion of the load A and of point b of sheave B, consists of two components.

One of these components is common to both, and is a motion wherein the linear distance between the points a and b is preserved and remains equal to the free length of the rope. The second component is superposed on the former, and corresponds to the varying elongations due to the rope's elasticity.

It will be seen that the component first named is the motion which would take place if the rope ab were non-extensible. In general, the motion of each machine part is the same as the motion which it would have if all of the machine parts were rigid, superposed by a motion relative thereto. It is this relative motion which is neglected if the calculations are based on the assumption of a state of equilibrium, or if all of the machine parts are assumed to be rigid.

The energy equations for the rigid and relative motions are easily derived from the general energy equation, and may be integrated separately. To prepare for the integration of the energy equation of the relative motion, the author makes use of the so-called theory of normal coördinates, which is explained at sufficient length in the paper for ready application to the problem in hand. By means of this theory the displacements s_1, s_2 etc., may be expressed as the sum of a number of normal displacements, each of these being the product of a normal constant into a normal coördinate. Of the normal constants and coördinates only a few general types need be determined.

Of the external forces acting on the machine, all are constant with the exception of the motive force P. Strictly speak-

ing, the frictional forces are also variable, and are really functions of the motion of the machine. On the other hand, the coefficient of friction depends on a number of factors which are only imperfectly known. In addition, the frictional forces are, as a rule, very small as compared with the other forces acting on the machine parts. There is therefore no advantage in introducing needless refinement, and it is sufficient to consider the frictional forces as constant.

If it were possible to express the motive force in an explicit function of the time, the above-mentioned integrations could be executed easily, either mathematically or graphically. For machines yet to be built this is impossible. However, there is available for the further calculations what is known under the name of the motor characteristics.

The motor in general will be that machine part which is the seat of the motive force, irrespective of the latter being

163,000 lb. For the entire duration of this interval, taken at 0.005 seconds, the motive force is assumed to remain constant at 163,000 lb. Under these conditions the various displacements, rope tensions and piston speeds are determined. At the end of the first time interval the piston speed amounts to 0.578 ft. per sec., when from Fig. 2 it is at once found that a motive force of 155,200 lb. corresponds to that speed. For the second time interval the motive force is then assumed to be constant at 155,200 lb. and the calculations are repeated.

The results of the calculations are shown in the complete paper in various graphs, of which four are here given in Figs. 3, 4, 5 and 6.

Particularly instructive in regard to the phenomena occurring at the start is Fig. 3, in which curve No. 1 represents the velocity of the piston, and curve No. 2 the velocity of the load A. Owing to the small inertia of the piston masses, it

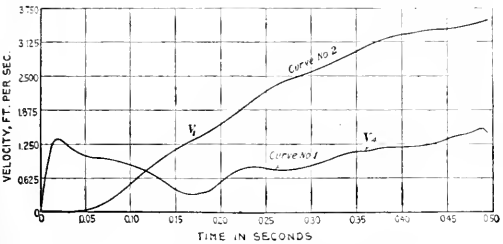

Fig. 3 Absolute Velocities of Piston (Curve No. 1) and of Load (Curve No. 2)

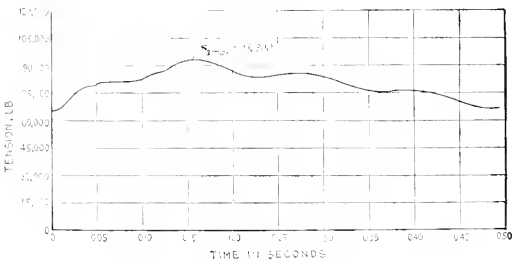

Fig. 6 Tension S_3 in Rope ef of Fig. 1

due to electric, hydraulic, steam or gas pressure. As is known, the force or torque exerted by these motors varies with the motor speed, although the manner in which these variations take place is frequently too complex to be adequately expressed in a mathematical formula. Fortunately, the latter is not necessary for the purpose in hand, since it is always possible from tests with the motor alone to derive a graph showing the variation of the motive force with the motor speed.

In the present case, the motor characteristics will be the performance of the piston alone when operating in the cylinder under the given conditions as to piping and water pressure. They are represented by Fig 2, which shows the net force P which the piston rod will exert at various piston speeds.

The calculations proceed by dividing the starting period into time intervals of so small duration that the motive force during any such interval may be considered constant, without that an appreciable error is committed.

For the first time interval, beginning with zero piston speed, it is found from Fig. 2 that the motive force P amounts to

must of course be expected that at the application of the motive force the equilibrium of the piston will be violently disturbed, while the effect on the heavy load will be less severe. This is clearly reflected in Fig. 3, where the piston speed rises from zero to 1.35 ft. per sec. within about 0.02 sec., whereas the velocity of the load after a lapse of even 0.05 sec. amounts to only 0.03 ft. per sec. That such conditions, nevertheless, do not lead to heavy stresses in the ropes is due to the nature of the motive force. Large variations in the piston velocity cannot persist, since the motor characteristics are such that an increase in the motor speed corresponds at once to a drop in the motive force (see Fig. 2), and vice versa. The motive force, therefore, has the tendency to counteract large variations in the piston speed, as witnessed by the smoother course of curve No. 1, Fig. 3, after the first violent rise. If the ropes of the machine of Fig. 1 were non-extensible, or as soon as the machine was running at constant speed, there would be a 2:1 ratio between the motion of the load and that of the piston. Owing to the elasticity of the ropes, however, there is no

vestige of any such ratio during the start, as will be seen from an inspection of Fig. 3. After a lapse of 0.05 sec., for example, the ratio between velocities of load and of piston is as much as 1:55; after 0.117 sec. it is 1:1; after 0.3 sec. it is approximately 3:1.

The rope tensions as they vary with time are shown in Figs. 4, 5 and 6. In the state of equilibrium $S_1 = 58,000$ lb., $S_2 = 61,000$ lb., and $S_3 = 64,300$ lb. During the start, however, $S_{1max} = 83,700$ lb., $S_{2max.} = 85,800$ lb., $S_{3max.} = 93,300$ lb., exceeding the former by 44.2 per cent, 40.5 per cent, and 45 per cent, respectively. It will be seen that in the present case the forces S_1, S_2 and S_3 are not very considerably in excess of the values which they have as soon as the machine runs at constant speed. This is primarily due to the nature of the motive force, as already explained.

From the foregoing it follows that the stresses in a machine at starting or stopping depend on a number of factors, namely:

1 The inertia of the individual parts, in particular the inertia of the motor in respect to that of other parts. The heavier the motor mass, the less violent will its equilibrium be disturbed at the start and the smaller the resulting stresses

2 The position of the motor mass within the system. The effect of a locomotive, for example, placed at the head of a string of cars, will be quite different than when placed in the middle

3 The elasticity of the individual machine parts

4 The distribution of the elasticity throughout the system. If, for instance, the equilibrium of the motor is liable to be violently disturbed at the start, the stresses in the machine will be less if the motor is coupled to the remainder of the machine by very elastic members

5 The nature of the motive force. In the hydraulic machine of Fig. 1 the drop in the motive force is approximately proportional to the square of the piston speed. Had the motor characteristics been such that the drop in the motive force was only proportional with the piston speed, far larger stresses would have resulted.

THE ELASTIC INDENTATION OF STEEL BALLS UNDER PRESSURE

By C. A. BRIGGS, WASHINGTON, D. C.

Member of the Society

W. C. CHAPIN,[1] and H. G. HEIL

Non-Members

In the adjustment and standardization of precision apparatus at the Bureau of Standards incidental to the testing of munition gages, the subject of the effect of pressure on the dimensions of steel balls and length standards having rounded ends came up for consideration. After a preliminary study of the matter it was concluded that the distortion of the steel balls between the contacts, and the elastic compression of the portion of the rounded ends not directly in contact with the measuring surfaces, was very small, a conclusion that appeared inconsistent with some of the results that had been obtained in actual measurements. This directed attention from the main portion of the steel ball or rounded surface to the elastic indentation of the surfaces immediately in contact with each other. In order to settle the questions arising, experiments were undertaken, and the results obtained form the substance of this report.

These experiments, while limited in scope, were so successful in giving consistent results and data of apparently wider application than that originally intended, that it appears desirable to make a brief report summarizing and recording the information obtained. Owing to the fact that the effect of high pressure was of no immediate interest in reference to the problem in hand, and to the fact that to extend the investigation to greater pressures would have required time that was needed for other matters, low pressures only were employed.

The maximum pressure used on steel balls against glass plates was 20 lb., which was used on balls ¾ in. and 1 in. in diameter. On smaller balls the maximum pressure used was 10 lb. The results, therefore, do not represent conditions present when high pressures are used, such as occur in the Brinell hardness test of materials where the stresses are above the elastic limit; or pressures such that the indented area includes a solid angle large enough to invalidate the assumption frequently made when the angle is small that the sine and angle are equal. However, the results obtained do give accurate information of the effect of pressures on the measured diameters of spherical surfaces of steel or other materials which are employed in standardizing gages; and also appear to give information of practical value as to what occurs in ball bearings.

The experiment was performed by observing and measuring with a micrometer microscope the area of contact made by flat and spherical surfaces in contact with each other under varying pressures. This area of contact was viewed as the central spot in the Newton's ring system formed when a glass surface was in contact with a polished surface of steel or with another glass surface. The amount of indentation was obtained from the measured diameters by a very simple computation, easily derived, which it is not necessary to give at this time.

The different combinations of surfaces available for observation and use in the experiments were: a steel sphere pressing against a flat glass surface; a spherical glass surface pressing against a flat steel surface; and a spherical glass surface pressing against a flat glass surface.

From an examination of the results for each pair of surfaces in contact plotted on log paper, and from general reasoning based on the nature of the phenomena, a general equation was worked out for the purpose of correlating all of the results. It is not necessary for present purposes to expand this report by giving all of the various considerations which lead to the particular form assumed for this general equation—suffice it to state that after the constants of the general equation had been determined from the experimental data, the experimental values were reobtained by computations from the general equation, and the agreement between the computed and experimental values was very good. In fact, the agreement was so satisfactory that it was considered unnecessary to take additional data from the same material, as had been contemplated up to that time.

In the case of steel against steel it was of course not possible to observe the area of contact owing to the opaque nature of both contact surfaces, so that the values of steel against

[1] Division of Weights and Measures, Bureau of Standards, Washington, D. C.

steel were obtained by the use of the general formula which had been found to fit all the various surfaces and materials used in the experiments.

It will be noted in the equations which follow that a quantity called the "indentation modulus" is used to express the elastic property which determines the indentation. It was originally intended to use Young's modulus as representing in a general way the elastic properties. However, on looking up the elastic constants of glass it was found that a problem of very similar nature had been worked out by Hertz from theoretical considerations which gave practically the same form of equation as was derived in the present experiments.

in contact with cylindrical surfaces—such as are represented by many forms of ball and roller bearings in every-day use. It would be also of interest to extend the experiments already made by employing higher pressures.

The elastic coefficients for the materials used in the experiment of this report were obtained from tabular data. If, in the future, it becomes desirable to obtain information on the indentation of surfaces with great precision, experiments should be performed on materials that have had their properties carefully measured, so as to fix with exactitude the values of Young's modulus and Poisson's ratio for the particular steel and glass used in the experiment.

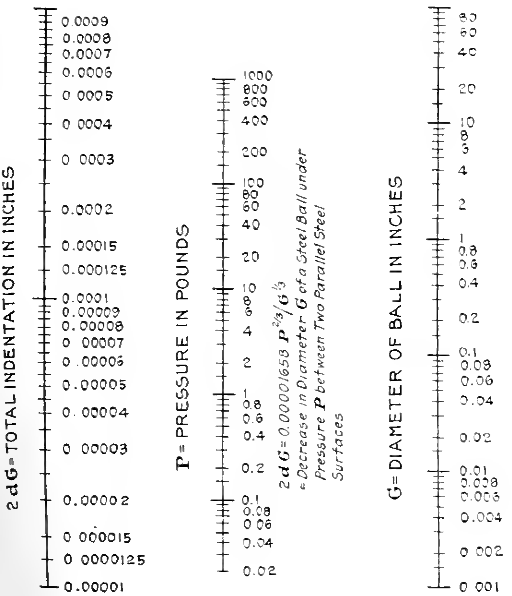

Fig. 1 Chart for Determining the Indentation of Steel Balls

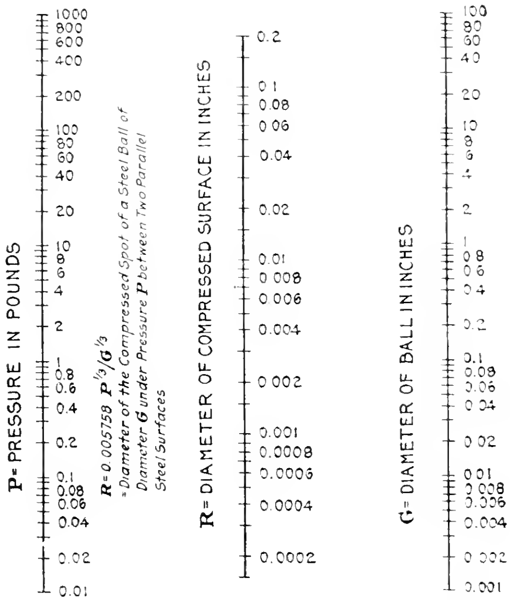

Fig. 2 Chart for Determining the Diameter of the Indented Spot of Steel Balls

and in which the elastic property effective in determining the indentation was found by Hertz to be a function of Young's modulus and Poisson's ratio, and which was called the indentation modulus.

A very interesting feature which can be noted on examining the results is that the indentation is not linear with the pressures but is proportional to the two-thirds power of the pressures. This is a fact of important interest in connection with the design of ball bearings, as it indicates what effects are produced on the distribution of the load by slight variations in the size of the balls in a bearing.

For steel against steel, which is the case of most general and important interest, the results are given in the form of computation charts, Figs. 1 to 3, by means of which numerical values can be obtained quickly for any particular case covered by the equations. (Three other charts, in which metric units are used, are given in the complete paper.)

In reference to future experiments, those which would appear to be of most practical interest are concerned with the determination of the elastic indentation of spherical surfaces

The results of the experiments are summarized in the eight equations which are given below.

General Equation for Indentation:

$$dG = 0.518\sqrt[3]{P^2[(G_1 - G_2)/G_1G_2][(1/E'_1)+(1/E'_2)]^2} \quad [1]$$

where

dG = the mutual indentation between the surfaces in contact

P = the pressure acting between the two surfaces

G_1 and G_2 = the radii of curvature of the two surfaces

E'_1 and E'_2 = the indentation moduli of the surfaces G_1 and G_2.

The indentation modulus is given by the expression

$$E' = E/(1 - u^2) \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

where E = Young's modulus and u = Poisson's ratio. The constant 0.518 is the same for both metric and English units when either are used consistently throughout the formula.

Indentation of Steel Balls Between Flat Steel Surfaces. For metric units the indentation is given by the equation

$$2dG = 0.00210\sqrt[3]{P^2/G} \quad \ldots\ldots\ldots\ldots\ldots [3]$$

where $2dG$ is the indentation in millimeters from both sides of the ball. For English units the equation is

$$2dG = 0.0000166\sqrt[3]{P^2/G} \quad \ldots\ldots\ldots\ldots\ldots [4]$$

where $2dG$ is given in inches.

Diameter of Area of Contact Between the Surfaces, Steel Against Steel. For metric units

$$R = 0.0647\sqrt[3]{PG} \quad \ldots\ldots\ldots\ldots\ldots [5]$$

where R is the diameter of the spot in millimeters. For English units—

$$R = 0.00576\sqrt[3]{PG} \quad \ldots\ldots\ldots\ldots\ldots [6]$$

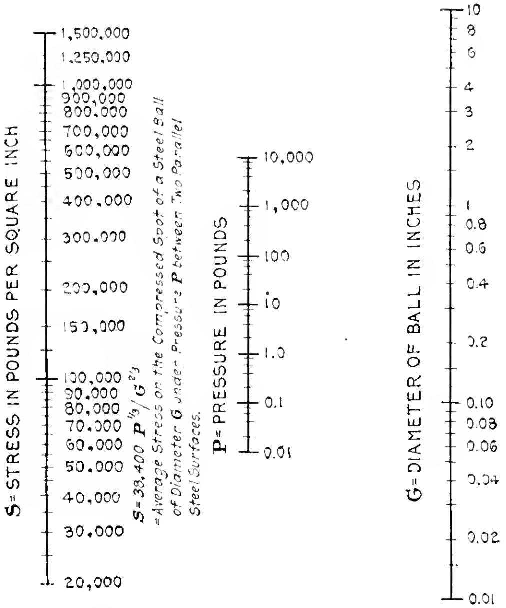

Fig. 3 Chart for Determining the Pressure per Unit Area on the Indented Spot of Steel Balls

where R is given in inches. If the general equation is desired for R it can be derived easily from Equation [1].

Average Pressure Over the Area of Contact, for Steel Against Steel. For metric units—

$$S = 301\sqrt[3]{P/G^2} \quad \ldots\ldots\ldots\ldots\ldots [7]$$

where S is given in kilograms per square millimeter. For English units—

$$S = 38{,}400\sqrt[3]{P/G^2} \quad \ldots\ldots\ldots\ldots\ldots [8]$$

where S is given in pounds per square inch. If the general equation for S is desired it can likewise be developed from Equation [1].

Computation Charts. Means for graphically solving the preceding equations in English units are shown in the charts Figs. 1, 2 and 3. A straight line placed across any of the charts will strike readings on the vertical scales which are a solution of the corresponding equation. With these charts, when any two of the three quantities of the equation are given, these quantities will establish two points which determine a straight line, and the value of the third quantity will be given by the intersection of the straight line on the corresponding vertical scale.

ELECTRIC HEATING OF MOLDS

By HAROLD E. WHITE, AMPERE, N. J.

Member of the Society

SYNTHETIC molding materials are being used on an increasingly extensive scale not only for parts of electrical machinery, but for many other articles of usefulness. It is the purpose of this paper to describe a novel method of applying heat to the molds in which such parts are formed, which the writer believes will be of general interest and of considerable utility under certain conditions.

The earliest example of such a material is perhaps hard rubber or vulcanite. More recent examples are the phenolic condensation products sold under various trade names. All of these materials are alike in that a moderate degree of heat causes them to soften sufficiently to take the form of the mold, while a higher degree of heat causes them to undergo chemical changes that harden them into a highly resistant condition.

Manufacture of parts made of this material on a small scale under the observation of the writer led to the development of the new method of production which is described. While it is not believed that this method can replace the methods used in factories which specialize on these materials, it would appear, nevertheless, that it can be used with success in almost any machine shop equipped with a hydraulic press, or even an arbor press if the articles are small, provided alternating current is available.

At first an attempt was made to use the standard method of production, which was to place the filled molds between two steam-heated plates attached respectively to the upper and lower platens of the hydraulic press. Live steam at about 110 lb. per sq. in. was admitted to these plates until the pieces were fully hardened. Then cold water was circulated through the same plates until the mold was cold, after which the mold was taken out and refilled for another piece.

Under these conditions production was slow and frequently interrupted altogether. The slowness of production was due to the fact that heat was not transmitted rapidly enough from the hot plates to the mold because the steam was often wet and the plates had a lower temperature than the boiler pressure would indicate. These difficulties were accentuated by the fact that most of the molds were long and slender, so that they had but a small part of their surface in contact with the hot plates and a large part of their surface in contact with the air. The heating and cooling of the fittings alternately carrying the steam and the cooling water resulted in frequent leaks, especially in the flexible piping, the use of which was necessitated by the movement of the upper platen of the press.

During one of these periods of interruption recourse was had to a method of electrical heating with such good results that the use of steam was abandoned altogether. In brief, the method consisted in magnetizing the molds with alternating current at 60 cycles. As these molds are always made of steel and generally hardened, they will heat up rapidly under these conditions, due to induced electric currents in the various parts of the molds, and also in some measure to hysteresis losses, especially in the hardened parts.

The method as at first used was simple in the extreme. The coil was made of 100 turns of No. 6 asbestos-covered wire, and when in operation its terminals were connected by a switch

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here presented in abstract form, and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

directly to the 220-volt supply line. With molds weighing 10 to 15 lb. a curing temperature could be reached, starting cold, in from 3 to 5 min. It should be understood that under the conditions of working the magnetizing coil remains quite cool.

The heat is developed in the interior, though mostly near the surface, of the molds. If the current is left on indefinitely a temperature destructive to the molding material results. This necessitates some way by which a definite result may be secured. Generally, it is sufficient to make trial pieces, noting the time of heating of each by a watch or clock. A good method of gaging the temperature of the molds is to observe the color of sulphur when melted in contact with the mold. A better material is a cane-sugar syrup with a little blue litmus, which clings to the hot molds and chars to a tobacco-brown when the temperature limit has been reached.

A study of the heating action in detail is interesting. Referring to Fig. 1, P' and P'' are the cast-iron platens of the press, M the matrix, and K' and K'' the plugs by which the molding material D is pressed in the matrix. C is the current-carrying coil. Since the magnetic field is the means of carrying the energy to the mold, it will be seen by those familiar with electromagnetism that the part of the mold in the plane of the coil heats most rapidly. The ends of the mold in contact with the platens lose heat rapidly, so that it was found well to protect them against such loss by asbestos or pasteboard sheets at Z. Next, several coils of different proportions were made, long ones for the longer molds and flatter ones for the shorter ones.

It was found inconvenient to lift the hot molds from the interior of the coils, so a further improvement was made in which the coils were divided into two halves and mounted as shown in Fig. 2, in which letters designate the same parts as in Fig. 1. This arrangement gives good heating throughout the mold regardless of the shape. In fact, there is a little greater heating at the ends, which compensates for loss by

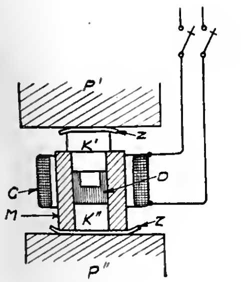

Fig. 1 Elementary Arrangement of Heating Coil

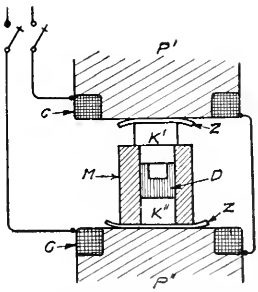

Fig. 2 Improved Arrangement with Coils Above and Below

conduction. The plates P' P'' were fitted with laminated-iron sections so that a path for the magnetic flux in them, which would not develop heat, could be provided. Fig. 3 is a photograph of the press fitted with these coils. It is evident that the molds could be put into or removed from the press thus fitted as readily as from an ordinary press.

In all of these arrangements the magnetic return circuit consists of leakage through the air and through the massive parts of the press, in all of which the magnetism is so diffused that the energy loss is small. This is clear from the fact that such losses are a function of the square of the magnetic density and the electrical conductivity of the material. Cast iron being of low conductivity, losses in the heavy parts of the press are necessarily very small. Cast iron would not be a good material from which to make the molds. It is evident that the thermal efficiency of this method is comparatively high. The writer has good reason to believe that more than half of the heat which is developed makes its appearance in the mold.

By the induction method of heating it is possible to pile several thin molds on top of each other and heat them all at once. This is not possible by any other method. By this

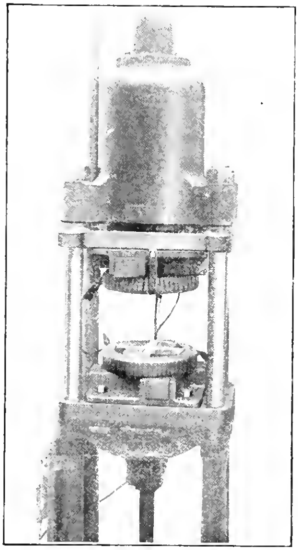

Fig. 3 Hydraulic Press Fitted with Coils as Shown in Fig. 2

means one press can be made to produce several articles simultaneously.

In making molded insulation the cost of molds is frequently very great. By the induction method of heating the cheapest possible mold can be used, since it is never necessary to so shape it as to admit steam to it, or so as to favor the flow of heat into it from any external source.

Many electrical engineers would regard the low power factor at which such devices operate as a serious drawback. However, the writer regards it as an important advantage in that a steadying effect on the circuit is produced, so that whether a large mold or a small mold, or no mold at all, is placed in the coil, no harmful result will follow, the large size of wire used being sufficient for the current at all times. Measured up in terms of value received for the outlay and freedom from trouble and general convenience, the process was entirely satisfactory. A press having a better magnetic circuit which would have operated at a power factor comparable to that of an induction motor could have been made at a greater cost, but the extra cost would have exceeded the saving possible during the time the above apparatus was in use, which was about one year.

It is believed that other uses might be made of this process; for example, die castings of readily fusible metal might be made economically on a small scale; or hardened-steel parts might be tempered, in which case the temper could be drawn without overheating sharp angles and cutting edges.

NEW THEORY OF AIR-PROPELLER ACTION

By MORGAN BROOKS, URBANA, ILL.

Member of the Society

THE term air screw, considered by many writers on aeronautics as descriptive of propeller action, is a misnomer. The theory of the marine propeller, which seems to be adequately presented by the screw principle, has been transferred to air propulsion without sufficient regard for the extreme difference in the two fluids as to elasticity.

In view of the current theory that air is driven by a propeller with a velocity which should not exceed the product of the pitch of the propeller by its revolutions, it was a surprise to find that air may be driven backward at a velocity nearly twice as great as this product indicates. The fact was so revolutionary that it caused the greatest care in measurement before its acceptance. Recognition of this superspeed action of propellers explains many anomalies of air propulsion and will undoubtedly lead to more exact formulæ for thrust and power calculations.

The purpose of this paper is to give proofs of the above possibility and to point out some of the applications of superspeed theory as it relates to propellers and blowers.

Superspeed is not readily observant with the standard type of two-blade propeller owing to the masking of this effect by the mingling of high-speed air with a much larger quantity of inert air lying between the propeller blades. Therefore the measurements were made upon a special type of propeller having extremely short blades of great width, sweeping the entire circumference of the disk area.

A propeller of the wide-blade type described having an experimental mean pitch of 2.53 ft. gives a wind on static test that flows 3.33 ft. per revolution, regardless of the speed of the propeller. These values were determined for the writer by Prof. E. P. Lesley at the Leland Stanford Jr. University wind tunnel, confirming the writer's own measurements. The superspeed ratio, 3.33/2.53, is 1.32, and these figures bear so direct a trigonometrical relation to the blade angle as to suggest that air instead of being swept backward by screw pressure is driven back by precise reflection or batting action.

The reflection theory is supported by data obtained with a blade of 28 deg. angle and by other confirmatory tests. In this connection an investigation was also made of the more complex condition of a propeller operating in a wind tunnel with wind conditions corresponding to those on a flying plane.

Among other things it was found that for low blade angles, where the superspeed ratio is more pronounced, the air leaves the propeller at higher velocity near the blade tips than part way in, a condition inconsistent with the screw theory for standard-type constant-pitch propellers.

Eiffel in his "Recherches" presents an elaborate collection of data showing that this condition exists, but the reflection theory for the first time explains it.

Light ribbons placed in the air flow from a static propeller show that the air moves in a direction strictly perpendicular to the blade angle, a condition determined by the reflection theory but not by screw action. Moreover, these ribbons indicate that the stream contracts slightly in diameter as it leaves the propeller, whereas with the squeezing action of a screw the air would be expected rather to expand.

The most convincing demonstration of the fact that the air leaves a propeller at a greater velocity than the propeller screw advance is found in a test made with two propellers connected in tandem. Calling the forward propeller a blower for the sake of distinction, assume that it provides a wind at 30 miles per hour, or 44 ft. per sec., and that the propeller is driven by this wind at a speed just above idling speed, such that its revolutions times pitch is, say, 48 ft. per sec. An anemometer shows a velocity of about 50 ft. per sec., but if the blower be shut down while the speed of the propeller is maintained constant, the wind velocity rises to 75 ft. per sec. instead of remaining constant as demanded by the screw theory.

The acceptance of superspeed action gives a basis for the evolution of dynamic thrust equations without the questionable assumption of blade activity over a larger portion of the propeller disk than that covered by the blades alone. The proper interpretation of superspeed may reconcile thrust and power values as derived from static tests with those of wind tunnels or of flight. Today it seems to be the common opinion that flying performance may not be predicted from static tests. With the precise air-dynamics formulæ sure to be developed, a single static test of a propeller should furnish all necessary data for the production of complete flying-performance curves.

The writer shows analytically that apparently the wind-tunnel blower relieves the propeller of a portion of the static thrust at a given propeller speed represented by idling speed, even though the propeller giving superspeed sends air backward when tested statically at the speed V/p, where V is plane velocity and p the propeller pitch. The writer shows that under his formula the flying thrust at 30 per cent slip is found to be 51 per cent of the static thrust at the given propeller speed.

The writer does not believe that correct air-dynamics formulæ will produce essential changes in propeller design, but hopes that the paper may lead to a clearer conception of the underlying physical principles of air propulsion.

A HIGH-SPEED AIR AND GAS WASHER

By JOHN L. ALDEN,[1] WASHINGTON, D. C.

Member of the Society

THIS paper describes a new type of air and gas washer which has been developed within the past eighteen months, and which offers the following advantages over the existing types:

1 The washing can be continued to any desired degree of cleanliness.

2 The washer will handle unusually large quantities of dust or long fiber without clogging, owing to its large passages and entire absence of eliminators.

3 Due to the high washing efficiency, the water consumption is very low, from 1 to 2 gal. per 1000 cu. ft. of air.

4 The washer is extremely small and compact, and of light weight. A 10,000-cu. ft. washer is about 5 ft. long, 5 ft. in diameter, and weighs less than 400 lb.

In this paper the term "air" will be used to include any

gaseous fluid or vapor for which cleaning apparatus may be suitable.

The writer has believed for some time that air washing and gas cleaning have been approached from the wrong angle, and that most builders of apparatus for this purpose have not taken advantage of all of the natural laws governing the depositing of air- or gas-borne particles. The result has been the general adoption of crude and unmechanical designs, and has made necessary the use of low velocities of gas through the machine. Gas scrubbers normally operate at a velocity of about 90 ft. per min. and air washers at from 400 to 500 ft. per min., while with these devices the limiting velocity for good washing and a reasonable frictional resistance is about 1000 ft. per min. The washer about to be described operates habitually at from 2000 to 5000 ft. per min. As the efficiency of air cleaning in this type increases rapidly with the velocity, the only limit to the latter is the resistance imposed.

Fig. 1 represents a longitudinal section of the air washer referred to above. A helical passage is constructed within a horizontal drum, provided at one end with a tangential inlet for the dirty air and at the opposite end with an outlet for the purified air. That portion of the helical passage nearest the inlet constitutes the washing chamber, while the remainder comprises the eliminating element. On the inner wall of the helical duct are suitable spray nozzles which spray across the column of air. Depending upon the amount of dust to be removed and the completeness of washing desired, the air makes from 1¼ to 5 screwlike revolutions in passing through the helix from inlet to outlet. For fairly dusty air or for the ordinary dust-collecting system, two turns are sufficient. The whole or a portion of the first turn is used for washing while the last turn is employed for the elimination of the free moisture.

The common commercial air washer with which we are all familiar depends upon its spray nozzles to throw down the dust particles and upon the eliminator plates to catch and retain the particles which have not actually been met by the sprays. The immediate result is low washing efficiency, if we consider water consumption as a measure of washing efficiency. In the first place, it takes an enormous quantity of water divided into a large number of small drops well distributed over the entire washing area to insure the wetting of any considerable portion of the dust. It is necessary that each particle of dust deposited be brought into intimate mechanical contact with a drop of water. The deflection of the air currents through the zig-zag eliminator plates introduces a very limited amount of centrifugal washing when the eliminators are kept flooded. On the other hand, a washer depending upon centrifugal force alone to throw the dust particles out of the air column is limited to the handling of the coarser dusts and will not remove the minute particles which make up the bulk of the dust content of the atmosphere. The washer described in this paper makes use of both spray and centrifugal washing, with the greater dependence placed upon the latter. As the dust-laden air enters through the tangential inlet pipe it is thoroughly wetted by the mist of the spray chamber. Much of the coarser dirt is removed by the direct action of the spray. As the air is whirled through the helical conduit a large proportion of the remaining dust is thrown against the wet curved side of the washer, flowing off to the drain with the spent wash water. The extremely fine dust still remaining cannot be caught by ordinary means, for it is too light to be separated by centrifugal force. However, a considerable amount has been exposed to the mist to such an extent that, although not actually wet, its specific gravity has been increased by the moisture to a degree which will permit its removal centrifugally. Thus, an unusually high proportion of the dust content is removed.

After the washing operation the air passes through the eliminating portion of the washer, where it is freed of the suspended moisture. The elimination of water drops is effectually accomplished by centrifugal action, exactly as the dust itself was removed. It is unnecessary to introduce into this washer any form of eliminator plates such as are found in most commercial washers.

The high washing efficiency thus gained presents two possibilities, either of which is decidedly advantageous. Extreme dust conditions may be met with comparative ease; or, street air may be washed for ventilating purposes with an unusually small amount of water. One of the smaller sizes of these washers handles 4000 cu. ft. per min. of dusty air from a dust-collecting system, and from 50 to 100 lb. of mud is removed daily from the strainer basket. From 4 to 6 gal. of water per minute wash this dirty air to a sufficient degree of cleanliness to permit it to be returned to the room. While no measurements have been made of the dust content, this air has absolutely no dusty odor and has a decidedly pleasant, fresh "feel." These results, obtained from a practical commercial washer, not a laboratory product, show that air sufficiently dirty to show a decidedly smoky dust cloud can be washed with from 1 to 1½ gal. of water per 1000 cu. ft. That this air washer is clearly a step forward is shown by these figures, for the standard washer requires from 4 to 5 gal. per 1000 cu. ft. to successfully wash air which is initially much cleaner than that on which the centrifugal washer was tested. Where it is impossible to recirculate the wash water, the economy in water alone is an appreciable item. For a machine to handle 10,000 cu. ft. of air per min. this amounts to 20,000 gal. per day of 10 hours. In addition to the actual cost of the water, the cost of pumping and the initial cost of pumps, motors, piping, etc., is considerably reduced.

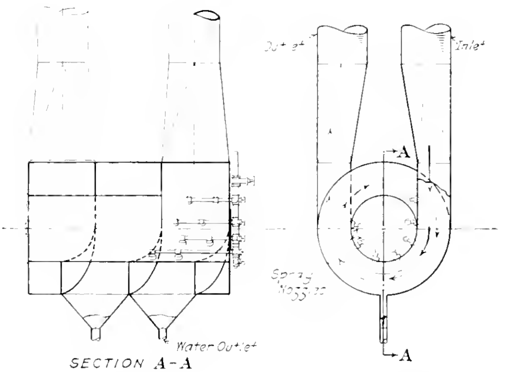

Fig. 1 Centrifugal Air Washer Shown in Section

Any material which may be separated from air by means of washing may be removed in this type of washer in any practical degree of thoroughness desired. This is accomplished by increasing the number of turns of the helical washing space. Thus, for ordinary ventilating purposes, 1 to 2 turns are sufficient; for dust collecting, 1½ to 3 turns; while for extremely fine dust, from 3 to 5 or more turns must be used. The economical limit is probably about 5 or 6 turns, or convolutions. The overall length, as determined by the number of turns of the

screw-shaped conduit, depends, therefore, upon the degree of purity of air desired, and to a very much less extent upon the relative arrangement of inlet and outlet. The outside diameter, on the other hand, depends upon the air volume. Since centrifugal force plays such an important part, the size of the washer is greatly reduced because the efficiency increases as the diameter decreases. In addition, the efficiency increases very rapidly with the higher air velocities. Both factors tend toward the production of a small, compact washer. The reason is very evident from the expression for centrifugal force:

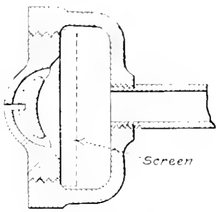

FIG. 2 SPRAY NOZZLE FOR USE IN AIR WASHERS

$F = mv^2/r$, where v = air velocity, ft. per sec., r = radius, ft., and m = mass. Thus, if satisfactory cleaning is done with a washer of 2 ft. mean radius of the washing chamber at 3000 ft. per min. velocity, an 8-ft. washer would require a velocity of 6000 ft. per min. to give equally good cleaning. It is therefore desirable to make the diameter of the washing drum as small as possible and at the same time use as high a velocity as is consistent with a reasonable friction loss. Owing to the fact that with increased diameters higher air speeds must be used to give the same cleanliness, it is probable that the practical limit of size for ordinary air washing is between 15,000 and 25,000 cu. ft. per min. High-speed air washers may be built in sizes as small as 100 cu. ft. per min., but both the upper and lower limits of size may be extended to meet unusual requirements. Table 1 gives the approximate dimensions of centrifugal air washers to be used for ordinary ventilating purposes. For other and special cases the dimensions will, of course, be different. It will be seen that in every case the washers are very small for the capacity; those already built and installed have been so small and light that they have been hung from the ceiling with band-iron straps, leaving ample headroom beneath.

TABLE 1 APPROXIMATE DIMENSIONS OF CENTRIFUGAL AIR WASHERS FOR VENTILATING PURPOSES[1]

Capacity, cu. ft. per min	Diameter, inches	Length, inches
2,000	30	36
4,000	40	42
6,000	48	52
9,000	56	60
12,000	64	72
16,000	72	80
22,000	80	90
30,000	96	108

[1] The exact dimensions vary with the air volume, the character of the dust, the relative positions of the inlet and outlet, etc.

The new washer described in this paper will supply a field hitherto untouched by the standard air washer. The latter is utterly unsuited to the handling of large quantities of fibrous materials, cotton, jute, hemp, wool, and miscellaneous waste. Large amounts of fine dust, shavings, or any other materials ordinarily handled by exhaust systems are beyond the capability of the common air washer. These substances will either clog the eliminators or will pass completely through the ordinary commercial machine. On the other hand, it is extremely difficult to clog the centrifugal air washer with dirt and refuse, owing to the large passages and to the entire absence of eliminator plates or other obstructions. It is unnecessary to interpose between the washer and the source of dust any form of dust collector or rough washer. Since the dirt and water are removed at each convolution of the helix, there is no accumulation of water and material to be reëntrained by the air current. This is an essential feature where the centrifugal removal of free moisture from a high velocity current is attempted.

With the air flowing through a rectangular passage, it is desirable to throw a flat spray of water across the channel. After considerable experiment with a variety of forms, the nozzle shown in Fig. 2 was designed to fulfill these requirements. The spraying tip is part of a removable plug containing two holes designed to throw opposing streams. The impact of the jets forms a flat sheet of spray at right angles to the plane of the holes. Although this spray is quite fine, much of it is further broken into mist upon striking upon the opposite wall of the washer. Locating the spray nozzles upon the inner wall of the chamber makes it necessary for all of the dirty air to pass through this fog-filled passage. This arrangement is much superior to that whereby water is allowed to flow from perforated pipes or nozzles over the outer cylinder alone, as it insures a thorough wetting of the dust taking place.

The pressure loss through the washer is from ⅛ in. to 1 in. of water, depending upon the conditions governing the design. The variables to be considered are the diameter, the cross-sectional area and proportions of the washing space, the velocity, the number of turns of the helix, and the volume of water per square inch of the sectional area of the washing chamber. Ordinarily, this washer can be designed for ventilating work with a resistance of about ¼ in. of water. Where the dust requirements are more severe, demanding higher velocities, more wash water and a greater number of convolutions of the helix, the loss will be somewhat greater.

Unfortunately, the writer is unable to give additional details of the performance of this washer, as his investigation of the first commercial installation was interrupted in May 1917 by the war. However, it may be said that two others were built from his design, and although he has not seen these either during construction or operation, they are reported by the owner to be in successful operation. Each of the later washers has a capacity of 15,000 cu. ft. per min., and was designed to hang from the ceiling with 7 ft. of headroom beneath. This type of washer was designed and developed for a specific job, that of washing the clouds of dust from the fan blast of dust-collecting system, leaving the air fit for breathing. The first experimental installation and the subsequent machines showed that for this purpose the washer was eminently satisfactory. The severe test of dust-collecting work, removing great quantities of dust from the air and returning the purified air to the room, justifies the belief that the centrifugal washer will easily satisfy ventilating requirements. Owing to the similarity of refined dust washing and blast-furnace-gas scrubbing, an investigation of the adaptability of this washer to gas cleaning would seem well worth while.

A SELF-ADJUSTING SPRING THRUST BEARING

By H. G. REIST, SCHENECTADY, N. Y.

Member of the Society

THRUST bearings for supporting the heavy loads of water wheels and the electric generators driven by them, are now very widely used. The difficulties in the fitting and use of plate bearings are much aggravated as the weight is increased, on account of the large overall dimensions of the supporting plate. It is true that the surfaces can be fitted quite accurately by machining, but the writer has known cases where the surfaces were turned slightly conical so that they touched hard on the inner or the outer edge. The deflection of the supporting collar on the shaft may allow the runner to be slightly dished, or there may be a deflection of the supporting surface, thereby dishing the babbitted seat or causing one side to be lower than the other. The self-adjusting spherical seat provided to correct some of these difficulties is of doubtful value on large bearings on account of the great frictional resistance which must be overcome to make it shift.

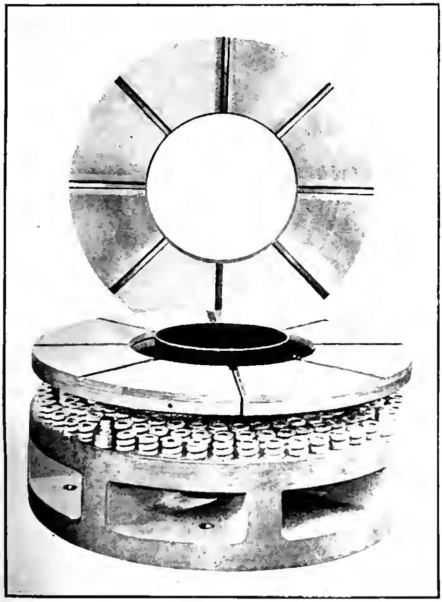

FIG. 1 SPRING THRUST BEARING, FOR VERTICAL WATERWHEEL-DRIVEN GENERATOR, TO CARRY A LOAD OF 300,000 LB. AT 100 R. P. M.

(View shows rubbing surfaces of both rotating and stationary rings, the latter being raised to show the arrangement of springs)

Thrust-bearing surfaces are usually scraped to each other, or to a surface plate, to avoid dangerously high spots; but, since the oil film is of the order of 0.0002 in. to 0.0003 in. in thickness, the difference in level must be smaller than these values. This work must usually be done without load, and no matter how carefully done, when the bearing is loaded the parts will probably not fit each other, due to deflection.

A careful study of the above difficulties led the writer to the design of a flexible bearing surface pressed against the runner by springs. It seemed that this would prevent the possibility of undue pressure at any point, and compel each element of the surface to carry its share of the load. On trial, this solution proved satisfactory.

A typical design of a spring thrust bearing for vertical-shaft machines is shown in Fig. 1. The bearing consists of a runner of a special grade of cast iron resting on a thin steel ring with a babbitted surface. The babbitted stationary ring, in turn, rests on short helical springs and is held against rotation by dowel pins. A saw cut through one side eliminates any tendency of the ring to dish with a change in temperature.

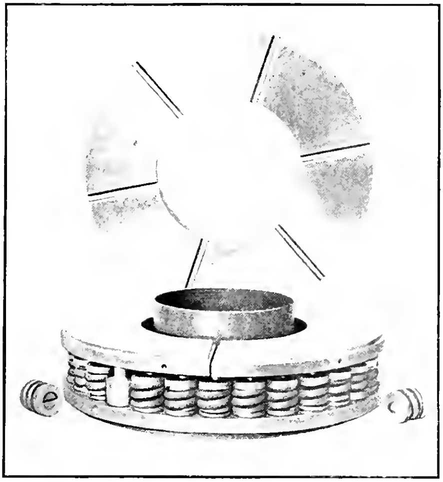

FIG. 2 SPRING THRUST BEARING WITH "COMPRESSED SPRINGS" FOR MACHINES HAVING SMALL CLEARANCES

(The stationary babbitted ring is raised to show springs and dowel pin)

The high base ring shown, on which the springs stand, is often used in connection with a deep housing to increase the amount of oil in the surrounding bath. The tube in the center forms a retaining wall around the shaft, for the oil. The springs ordinarily used are wound of $\frac{1}{2}$-in. round wire and have an outside diameter of 2 in. and a free length of $1\frac{1}{2}$ in. Under load the springs close about $\frac{1}{16}$ in. and the total pressure is well distributed. By this means it is possible to avoid excessive pressures at any point. Thus, it is safe to run with a much higher average pressure than when there is no definite limit to the pressure which may occur over a small area.

It will be seen that this type of bearing differs from the solid-ring thrust bearing in that one of the bearing surfaces is made to yield at any point by using a comparatively thin plate supported by a large number of springs. While solid bearings may be used successfully for small loads, a bearing which thus automatically adjusts itself to faults in finish and in alignment is preferable for carrying very heavy weights.

Oil grooves are provided in one of the members and sometimes in both. In order to insure proper circulation of the oil

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

for cooling purposes, in the case of bearings operating at low speed it is necessary to have grooves in the rotor. On high speeds these grooves may sometimes be omitted, relying for circulation only on the friction of the rotor on the oil while passing the grooves in the stator. In many cases we have had very satisfactory results by placing radial grooves in both the rotating and the stationary surface. It is our practice to have different numbers of grooves in the two plates, for instance, six and eight. With grooves in each of the surfaces we have a continuous flooding of oil on all the bearing surfaces and a very effective means of cooling. Much of the heat would otherwise have to be transmitted through the metal of the stationary part of the bearing.

The pressure usually allowed on these bearings is from 300 to 400 lb. per sq. in., the design permitting a very thin oil film without metallic contact. It is necessary to have the runner very smooth and free from scratches, especially any at an angle to the direction of rotation, as these might cause injury to the babbitt. The babbitted surface does not need to be scraped but is turned with a tool as smooth as is convenient. Wearing sometimes occurs in minute spots all over the plates. When this happens, there is no risk of dragging the metal. The bright spots that show themselves are produced while starting and slowing down, before a pressure film is formed. When in operation the weight is apparently entirely supported on the oil film.

It is desirable to run bearings at a high pressure if they can be designed to do this safely, as the parts then are smaller, the rubbing speed is less, and the friction very much reduced. With this design of bearing the tendency to excessive pressure at one point is automatically relieved by the springs yielding, and while there will be some uneven distribution, a variation in pressure of two or three times the average is comparatively unimportant and does not cause bearing failures,—it is pressures of twenty or more times the average that cause injury. These excessive pressures are prevented by the construction just described. For this reason it is safer to operate this bearing with high pressures than a more rigid bearing at lower pressures.

The loss of alignment due to settling of foundations or other causes does not affect the bearing adversely. In one water-wheel-driven alternator installation the striking of the field against the armature led to the discovery that the coupling between the two units had loosened, which allowed the shaft to "run out." The bearing operated without injury with over 0.03 in. vertical movement of the outer edge of the rubbing surface. This caused an uneven distribution of load on the bearing, to the extent of reducing the load on one side of the bearing about 16 per cent, and increasing the pressure a similar percentage on the extreme opposite side.

An advantage of increased pressure in the reduction of friction is shown by the following table of comparison:

Bearing number	1	2
Rev. per min.	200	200
Total load, lb.	300,000	300,000
Outside diameter of bearing, in.	35	46
Inside diameter of bearing, in.	17.5	17.5
Net area, sq. in.	600	1200
Pressure, lb. per sq. in.	500	250
Average rubbing speed, ft. per min.	1370	1670
Coefficient of friction	0.0018	0.0033
Kilowatt loss	16.7	38
Horsepower loss	22.5	51

In some designs the vertical clearance between the water wheel and the casing is very small, so that the displacement caused by a free spring under the variation of hydraulic suction is objectionable. In such cases an initial compression equal to full load, or to an overload, is put on the springs. The load will still distribute, since an overload at any point will cause the spring to close beyond the initial compression. Such a bearing is shown in Fig. 2. However, this bearing was designed to replace a roller bearing, and was so made that the parts of the water wheel would occupy the same relative positions as before. The principles used in the construction of these thrust bearings are applicable also to journal bearings and to bearing surfaces having a reciprocating motion, like the crosshead of a steam or gas engine.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

The High-Speed Motor and the Fuel Question

To the Editor:

In the past three or four years automobile engineers have developed a modified type of gasoline motor with piston speeds greatly in excess of what was considered proper and safe before.

Several causes are back of this development: first, the ability of the forging plants of the country to produce crankshafts with integral counterweights, which reduce the pressure on the bearings to a safe limit; second, the demand for smoother-running engines; third, the work done to develop lighter and more efficient power plants.

For some time it has been a question in the mind of the writer whether, in that search for higher speed, a cardinal point has not been overlooked—to the detriment of motor efficiency—in failing to take into account the vaporizing qualities of the fuel at our disposal during the past years.

In discussing this question of high-speed motors and fuel it must be remembered that the high-speed motor originated in Europe with the racing motors brought out by European designers in 1912, 1913 and 1914; and as the gasoline which they used was of a very high grade, they were successful in developing that type of motor; but our fuel being of a much lower grade, principles of design that can be used in Europe do not apply to conditions on this continent.

It is a fact that the quality of fuel sold as gasoline to the automobile owner has been gradually declining year by year. The enormous demand made upon the oil industry for a volatile fuel has resulted in the marketing of a fuel containing less and less of the main volatile elements of gasoline. The gasoline of the early days consisted mainly of pentane, hexane and heptane—elements which are very volatile and, conse-

quently, easily vaporized. Until 1914 the gasoline used in Europe was of that composition, while ours had already started on the decline. Since that period gasoline has passed from a by-product of petroleum to a main product, and therefore the heavier elements of petroleum have had to be incorporated in increasing volume to keep up with the demand. These elements comprise octane, nonane and decane, which are hard to ignite when mixed with air. However, if heat is applied to them before admitting them into the cylinder their inflammability is very much improved. These points being kept in mind, let us see what happens when we try to run a high-speed engine with these grades of fuel.

Not so very long ago 1000 ft. per min. was considered an average and efficient piston speed, but automobile designers, for the reasons stated above, tried to increase piston speeds to a point near 3000 ft. per min. Without entering into details of the improved lubrication necessary to take care of the increased friction, we find that the time given to the explosive mixture to reach the cylinder, to be compressed, exploded, and evacuated, has been reduced to one-third of what it was formerly. If the fuel used was very volatile, as the gasoline of older days, we might still consider it possible to burn the full charge of gas in the cylinder and evacuate it. But the fuel being much poorer, we think it is a physical impossibility to mix properly an explosive gas and burn it entirely in the limited time left for the explosion to take place. This is proved practically by the reports received from users of cars, principally of the higher-speed types. It is found that a portion of the mixture does not burn: it passes by the piston rings and goes down into the crankcase, where it dilutes the oil to the danger point, resulting in burned-out bearings and seizing of parts subject to friction. It is therefore evident that a speed of 3000 ft. per min. for pistons is not practical. Let us see what piston speeds we find in the best-developed engines at the present time.

It is a recognized fact that the highest form of gasoline motor today is the engine used in aeroplanes at the front. A comparison of the piston speeds used in the most modern battleplane motors of France, Germany, the United States and England discloses the fact that the highest piston speed maintained does not exceed 2000 ft. per min., and is closer to 1600 ft. per min. than to 2000—nearly half the piston speed used in the so-called high-speed motors. There is room for thought in this. It is our own opinion that these speeds are even a maximum which the commercial automobile motor used in either passenger cars or trucks should not exceed, and engineers who will study these motors in the future with this idea in mind will be more successful with their product than those who cling to the high-speed principle.

This fuel question is so complex that some other points have also to be considered. We shall mention the most important one—the starting of a motor in cold weather. Every one who is familiar with the driving of an automobile knows that in the cold morning temperatures which we experience on this continent great difficulties are encountered in starting the motor with some types of cars. Some of them will start easier than others, but from the writer's experience the starting qualities can be improved greatly by reducing the section of the inlet passages into the cylinders to permit of higher gas velocities. Also, if the carburetor is set very close to the cylinder, permitting the heat of the exhaust to warm up the inlet pipe, still better results can be obtained. The reducing of the inlet passages by tapering them gradually into the cylinder produces a better mixture which is exploded more readily with less residue and less carbon deposits in the explosion chamber and on the spark plugs. The writer has applied these principles to several engines designed in the past four years with marked success, and he has at the same time tried to limit the piston speed in these motors to a maximum of 1600 ft. per min., this design being in line with the ideas set forth above.

We are of the opinion that the qualities which attracted designers to the high-speed idea in gasoline motors can be taken care of as well with the slower types of engines and permit at the same time a better solution of the lubrication problem.

Flint, Mich.

Report on Pulverized Fuel

To the Editor:

I am enclosing an abstract of a report recently made to the President of the U. S. Shipping Board, on the use of powdered fuel for marine purposes. This report was prepared by the Fuel and Fuel Handling Committee of the Naval Consulting Board, of which the writer is chairman, in response to the following resolution by the Naval Consulting Board, November 17, 1917:

Resolved, That in view of the efficiency, economy and smokeless conditions which would accompany the use of powdered coal on ships, the Naval Consulting Board recommends to the United States Shipping Board that a thorough investigation be made of this subject and a trial plant be installed.

Spencer Miller.

New York, N. Y.

Abstract of Report

Pulverizing coal as a fuel is extensively employed in the arts for smelting, for burning portland cement and to a limited extent for generating steam. It is estimated that 50,000,000 tons of coal has been pulverized and consumed within recent years in the United States. In stationary practice definite economies have been claimed over the use of solid coal. From the above it appears that the art of pulverizing and burning coal as a powder has passed the experimental stage in certain arts.

From evidence placed before us pulverized coal is a smokeless fuel, a fact of considerable military importance.

By a simple and immediate adjustment of the burners, powdered coal as a fuel may be made to emit dense clouds of smoke to serve as a screen, another fact of military importance.

In an emergency the ship's boilers may be rapidly forced, thereby increasing the steam supply and the speed of the vessel. This is a fact of military importance.

A great reduction in the fire-room force is effected over using solid coal. This saving in man power has military value.

The supply of fuel oil in the United States is limited, and as a means of conserving fuel oil for naval vessels equipped to burn oil exclusively the Consulting Board feels justified in encouraging the use of powdered coal as a fuel for merchant ships.

The Fuel and Fuel Handling Committee was canvassed to vote upon the two following questions:

a Is it feasible to carry powdered coal on merchant or naval vessels such as would be used in transatlantic service?

One replied in the affirmative and three in the negative.

6. Is it feasible to install on any such ships apparatus to powder coal?

Four replied in the affirmative and one in the negative.

From the above it will be noted that, in the opinion of the Committee, which has been approved by the vote of the Board, it appears feasible to equip merchantmen with requisite machinery for pulverizing and burning coal, and we therefore earnestly recommend that the Emergency Fleet Corporation authorize the preparation of the necessary plans and drawings for such an installation upon such ships, and that a shore installation be made of such equipment to determine as well as may be the value of such an installation on board ship. Such shore installation can be set up and tested at the Annapolis Experiment Station, Annapolis.

A ship equipped with pulverizing equipment should, in the opinion of the Naval Consulting Board, be expected to take on coal in any port of any kind available and by the ordinary methods. In Atlantic ports this will be run-of-mine bituminous of high volatile and of high grade, sometimes dry and dusty and at other times quite wet.

Such coal on board ship, following shore practice, would then pass through the following processes:

Crushing in power rolls, and delivering to a storage bin.

Drying if found essential to remove the moisture prior to pulverizing, delivering to a second storage bin.

Extraction of iron particles. This being advised to save damage to the pulverizing mill. A magnetic separator is commonly used for this purpose.

Pulverizing, either in Fuller or Raymond mills or their equivalent, then storing in a third storage bin.

Mixing with air, feeding to furnace and burning.

After delivery of the raw coal to crushers the fuel will be handled by conveyors or spouts. All storage bins, conveyors and spouts must be constructed and maintained dust-tight as a means of preventing explosions, and possibly such may have to be made of non-corrosive material.

The Naval Consulting Board is at your service, and if it be your pleasure to proceed in the preparation of designs, estimates and specifications, we shall be honored by your seeking our aid in the solution of this important problem.

A Suggested Extension of the Scope of A. S. M. E. Transactions

TO THE EDITOR:

The Publication Committees of recent years are to be congratulated upon the character of our publications. There was a feeling of dismay among some members a few years ago when the discontinuance of the TRANSACTIONS was proposed. Happily, this situation has been adjusted, so that there are now only expressions of satisfaction.

It has occurred to me that we could with benefit include in our TRANSACTIONS more papers of general scientific value than has been customary. Such papers would not be of sufficient current interest to be discussed at either local or general meetings, but would be of such character as to be of future value to specialists in particular branches of our field. To use a slang expression, which, as is often the case, conveys a great deal of meaning in a terse way, I plead for the publication of more "high-brow" papers in our TRANSACTIONS. Of course, an innovation is not to be expected during these war times. However, the matter can be discussed and planned for, so as to be in operation by the time the war is over.

Our country is already taking an advanced position in the affairs of the world in many directions. We have, however, been somewhat backward in the matter of learnedness. There are French, English and even German publications extending back a century or so which contain epoch-making papers. Many of these papers had little or no current interest, and yet they are the foundation stones of our present scientific structures. We, in this country, must also lay such foundation stones for the benefit of our posterity if we expect to take the place in the world's affairs which we seem to be seeking. There are in this country at the present time but few places where abstruse mechanical-engineering papers can be published, as compared with England, France and Germany. Hence it seems necessary that our own TRANSACTIONS should be arranged so as to include such papers in greater number. The money put into their publication would, of course, not yield us immediate dividends, but would be a contribution to our successors. The net result of publication of such papers would be references to them by specialists of the future. Our own TRANSACTIONS would then stand alongside those of foreign societies as valuable works of reference. The value of an abstruse paper is measured by the number of times it is referred to in footnotes of later papers.

The lack of a vehicle for the publication of papers of the character described has, of course, discouraged abstruse mechanical-engineering research. The provision of a vehicle would, doubtless, stimulate research.

In order that this plan can be executed, two things are necessary:

(1) To secure an increased number of meritorious papers of the character described;

(2) To arrange for their publication.

Progress in either one of these directions will, of course, assist progress in the other. Our Secretary, Editor and Publication Committee are already in touch with various research laboratories engaged in mechanical-engineering work connected both with colleges and commercial establishments, and are endeavoring to secure papers from them. This effort should be assisted in every way by the membership. Many commercial establishments have been very broadminded in recent years in allowing the work of their research laboratories to be published. I have no doubt that papers from such sources will increase, particularly as there seems to be an increase in the amount of commercial research work being done.

After such papers have been secured they might be passed upon for publication by our Research Committee. The Meetings and the Publication Committees would then pass on to the Research Committee a paper which they decided was not of sufficient current interest to be read and discussed at a meeting. The Meetings Committee, of course, read a paper from an entirely different point of view from that of the Research Committee. If the Research Committee decided that the paper was meritorious, from their point of view, they would direct the Publication Committee to publish it. Such an arrangement would also give the Research Committee more direct responsibility in regard to securing such papers.

I understand that it has already been proposed that papers of the character referred to be printed in advance form, circulated previous to a meeting, read by title only at a meeting with request for written discussion, and published in the TRANSACTIONS if it finally seems advisable. If the Research Committee were made responsible in such matters they would direct the Publication Committee regarding both advance and final publication.

I have no doubt that a very satisfactory arrangement of such details can easily be managed if we can secure a sufficient number of good papers of the character described.

Urgent Need for the Inventive Ability of Mechanical Engineers

TO THE EDITOR:

In connection with the statement in regard to the work of the War Committee of the Engineering Council, printed elsewhere in this number,[1] I desire to urge that the mechanical engineers of the United States should give their thought and consideration, and above all should put their imagination to work, in order to invent new types of apparatus for waging war. It is the quality of imagination which will count in the fight. It is especially the imagination of the man who is technically trained which is of the greatest value. As a direct method the mechanical engineers of the country should give consideration to and make a study of the various types of weapons now in use, with the object of determining whether these types as they now stand are in fact the ultimate types. This sort of study will unquestionably stir the minds of technically trained men into the invention of many new types of weapons.

The theory on which the War Committee of Technical Societies, of which Mr. David W. Brunton is chairman, is based, is—that if the vast body of technically trained men in the United States could be stirred into consideration of weapons and apparatus of war, then there would be brought forth without question valuable types of weapons and apparatus which are at the present moment unheard of. Most of the present weapons have been brought forth in the manner of slow evolution, as has also been the case in the development of most machines. However, it is believed that by stimulating such an enormous number of minds the period of time of evolution will be shortened. It is further believed that valuable weapons may be produced by the combination of old and thoroughly evolved machines and ideas into new and effective machines.

It must be remembered that past experience has shown that the invention of valuable war apparatus and weapons has by no means been confined to the members of the Army and the Navy. It is a well-known fact that some of the most important war inventions have been those of civilians. This of course is also true in every industry; that is, valuable inventions in any given industry are very often made by men who are in nowise connected with that industry. This is due undoubtedly to the opportunity of the outsider to consider and judge without prejudice.

It is thoroughly well known that previous to the war inventions of civilians in connection with war apparatus were not cordially received by the Army and the Navy, and the situation in this country at that time was such that very few civilians were willing to lend assistance to the Army and the Navy. The day of these conditions is now past, however, and the day of great urgency has arrived. The ideas and inventions of the civilian trained engineer are of the utmost value to the Government and are cordially received. The mechanical engineer must enter into the fight, and he will be welcomed, as will also his ideas if they are good. Furthermore, the old handicap of cost and the handicap of the expense of investigation do not now exist, for the money and the credit have been provided and will be provided to meet the situation.

It is indeed the day of magnificent opportunity for the mechanical engineer!

R. N. INGLIS.

New York, N. Y.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 187-189, inclusive, as formulated at the meeting of March 28-29, and approved by the Council. In this report, as previously, the names of inquirers have been omitted.

CASE No. 187

Inquiry: Will not a method of suspension for h.r.t. boilers over 78 in. in diameter involving suspension in battery, using channel or I-beam girders resting on brick work with strap hangers and U-rods, meet the requirements of Par. 323, where the weight of the boiler is distributed uniformly and evenly over the setting walls, and very little, if any, of the weight comes on the firebrick lining? It is not believed advisable to place supporting columns of either cast iron or steel in a battery wall.

Reply: It is the opinion of the Boiler Code Committee that, as specified in Par. 323 of the Code, all h.r.t. boilers over 78 in. in diameter must be supported entirely independent of the side walls of the setting, in order that the side walls may be kept entirely free from troubles from settlement and cracking due to the weight of the boiler structure. This practice is known to be extensively followed by engineers, and is believed to be a necessary requirement for safety.

CASE No. 188

Inquiry: Is it allowable under the rules of the Boiler Code to flange the head of a round boiler of $13\frac{3}{4}$ in. radius, $\frac{5}{16}$ in. thick, on a 1 in. radius without heating?

Reply: The Committee considers the practice of flanging heads of boilers cold to be unsafe.

CASE No. 189

Inquiry: Is there a rule in the Boiler Code with regard to the use of single reinforcing straps where this type of construction is used to secure additional efficiency in tube elements? It is believed that by this construction, eccentricity of loading is worked beyond a reasonable limit, and that double straps, internal and external, should be used where reinforcement for tube elements is necessary.

Reply: The Committee agrees that for the particular purpose referred to, a double strap construction is better practice,

[1] Page 402, Society Affairs Section.

but it is deemed inadvisable to make a ruling that would prohibit generally the single strap reinforcement.

REVISION OF BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code, and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in THE JOURNAL, with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes before the Rules are brought to the final form and presented to the Council for approval. This has been done, and the revisions were presented in the March issue of THE JOURNAL, pp. 234-247, and in the April issue, p. 316, in the form proposed for submission to the Council, except as they may be modified by editing without change of sense. Discussions should be mailed to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y., and they will be presented and acted on by the Boiler Code Committee. Since the publication of the March issue of THE JOURNAL certain typographical errors have been discovered in the revisions there presented, and corrections of these were published in the April issue of THE JOURNAL; these are supplemented by additional corrections appearing below.

Any further discussions or criticisms, in order to receive consideration by the Boiler Code Committee before the new edition of the Code is published, must reach the office of the Secretary on or before the 15th of May.

PAGE 2

LETTER TO THE COUNCIL.

In the Letter to the Council, after the third paragraph of the matter published in the March JOURNAL, add two new paragraphs to read as follows:

> Your Committee have met monthly for the purpose of considering inquiries relative to the Boiler Code. The procedure in handling each Case is as follows:
>
> All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all members of the Committee. The interpretation in the form of a reply is prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is then submitted in typewritten form to each member of the Council of the Society, and to each member of the Committee. Where a single adverse criticism is received respecting any one of the interpretations, the inquiry is referred back to the Committee. Where there is no adverse criticism, the Council of the Society approves the interpretations which are then issued to the inquirer and simultaneously published in THE JOURNAL. In publishing the replies in THE JOURNAL, the names of firms and parties making the inquiries are withheld. Where there has been urgent need for haste, the Executive Committee of the Council of the Society has acted for the Council.
>
> In accordance with your instructions, each State and Municipality that has adopted the Boiler Code has been invited to appoint a representative to act on a Conference Committee to the Boiler Code Committee, such Conference Committee to consist solely of representatives of the States and Municipalities that adopt the Code. The States and Municipalities have responded by appointing representatives, who have attended the meetings and coöperated in the work of the Boiler Code Committee.

After the seventh paragraph of the matter published in the March JOURNAL, add four new paragraphs to read as follows:

> In the specifications for boiler plate steel, the range in tensile strength in pounds per square inch for firebox steel has been changed from 8000 to 10,000 lb., the tensile strength now specified being from 55,000 to 65,000 lb. per sq. in., which is the same as for flange steel. Your Committee believes that although there are certain features of the specifications for firebox steel which differentiate between the physical properties as compared with flange steel, that there should be a further differentiation. This feature has been taken up with the Sub-Committees of the American Society for Testing Materials, and of The Association of American Steel Manufacturers; but an agreement has not yet been reached. It was considered desirable not to delay the issuance of the revised Code until there could be an agreement; but to transmit the Code to you with the specifications in their present form, with the understanding that as soon as an agreement is reached a supplementary report will be submitted to you for your consideration.
>
> Additional tests for firebox steel, which in the opinion of the Committee would entail the least hardship with a maximum benefit, would be homogeneity tests on the bend test specimens, which are taken transversely from the middle of the top of the plate; the homogeneity tests to be made on the bend test samples after the bend tests are completed, thus requiring no additional specimens to be taken from the plate. Homogeneity tests are now specified for firebox steel on the tension test specimens taken from the lower part of the plate; and in the opinion of your Committee, it would be desirable to make additional homogeneity tests on the samples from the top of the plate where the metal is more apt to be segregated than near the bottom of the plate.
>
> The requirements for the homogeneity tests, at the top of the plate, may necessarily be different from those at the bottom of the plate; and until the requirements for the homogeneity tests at the top of the plate are determined by tests, the specifications cannot be changed to include the requirements.
>
> The rule for determining the strength of diagonal ligaments between tube holes in a drum, which is given in the preceding edition of the Code, has been found to be defective. Experiments have been made with a view of establishing a more exact rule. The experiments so far made indicate that certain theoretical curves which are published herein, in connection with Par. 193, are safe and accurate, and these curves are therefore offered for determining the efficiency of such ligaments. The experiments projected by your Committee are still proceeding, and it is possible that these may finally lead to minor modifications in the curves, in which case your Committee will present a new set of curves to take the place of those now offered.

PAGE 8

PAR. 12. IN THE SECOND LINE OF PAR. 12, CHANGE THE WORD "AT" TO "FOR."

PAGE 10

PAR. 22. CHANGE FIRST LINE OF TABULATED MATTER IN ORIGINAL PAR. 22 TO READ AS FOLLOWS:

> Diameters 1 in. or over but less than $2\frac{1}{2}$ in. . . . No. 13 B. W. G.

CHANGE THE TWO LINES FOLLOWING THE TABULATED MATTER TO READ:

> For each increase of one gage in thickness the maximum allowable working pressure will be increased by 200 lb. divided by the diameter of the tube in inches.

PAGE 12

PAR. 28. DIRECTLY AFTER SECTION *a* IN ORIGINAL PAR. 28, ADD:

b Should the above rule for minimum allowable elongation give a value of less than 24 per cent for firebox steel, the minimum allowable elongation shall be taken as 24 per cent, subject to the modification given in Par. 29.

CHANGE SECTION *b* TO SECTION *c* AND SECTION *c* TO SECTION *d*.

PAR. 31. ALLOW THIS PARAGRAPH TO STAND AS IT APPEARS IN THE PRESENT EDITION OF THE CODE (EDITION OF 1914), CANCELING ALL REVISIONS PROPOSED.

PAGE 44

PAR. 182. CHANGE PAR. 182 TO READ AS FOLLOWS:

182 The distance between the center lines of any two adjacent rows of rivets, or the "back-pitch" measured at right angles to the direction of the joint, shall have the following minimum values:

a If $\frac{P}{D}$ is 4 or less, the minimum value shall be $2\,D$;

b If $\frac{P}{D}$ is over 4, the minimum value shall be

$$\left[2 + 0.1\left(\frac{P}{D} - 4\right)\right] D$$

where P = pitch of rivets in longitudinal rows where a rivet in the inner row comes midway between two rivets in the outer row,

D = pitch of rivets in the outer row less pitch of rivets in the inner row where two rivets in the inner row come between two rivets in the outer row. (It is here assumed that the joints are of the usual construction where the rivets in any single row are evenly spaced.)

PAR. 184. IN SECTION *c* OF PAR. 184 INSERT AFTER THE FIRST WORD "IN" IN THE FIRST LINE THE FOLLOWING WORDS:

"the portion of"

IN THE SECOND LINE AFTER THE WORD "BOILERS" INSERT THE FOLLOWING:

"exposed to the products of combustion,"

PAGE 47

PAR. 193. CHANGE PAR. 193 TO READ AS FOLLOWS:

193 When a shell or drum is drilled for tube holes in the line diagonal with the axis of the shell or drum, as shown in Fig. 12, the efficiency of the ligament between the tube holes shall be that given by the diagram, Fig. 12*a*.

In this diagram the abscissae are $\frac{p}{d}$ and the ordinates $\frac{p'}{p}$, where

p = longitudinal pitch of tube holes, or distance between centers of tubes in a longitudinal row, in.
p' = diagonal pitch of tube holes, in.
d = diameter of tube holes, in.

To use the diagram, Fig. 12*a*, the values of $\frac{p}{d}$ and $\frac{p'}{p}$ are computed and the efficiency for the corresponding point is read off from the diagram. Should the point fall above the curve of equal efficiency for the diagonal and longitudinal ligaments, the longitudinal ligament will be the weaker, in which case the efficiency is computed from the following formula:

a $$\frac{p - d}{p}$$

Examples: 1st, diagonal pitch of tube holes in drum as shown in Fig. 12 = 6.42 in.
Diameters of holes = 4 1/32 in.
Longitudinal pitch of tube holes = 11½ in.

$$\frac{p}{d} = \frac{11.5}{4.031} = 2.853$$

$$\frac{p'}{p} = \frac{6.42}{11.5} = 0.558$$

The point corresponding to these values is shown at *A* on the diagram, Fig. 12*a*, and the corresponding efficiency is 36.3 per cent. As the point falls below the curve of equal efficiency for the diagonal and longitudinal ligaments, the longitudinal ligament is the weaker.

2d, diagonal pitch of tube holes in drum = 6 35/64 in.
Diameter of tube holes = 4 1/64 in.
Longitudinal pitch of tube holes = 7 in.

$$\frac{p}{d} = \frac{7}{4.0156} = 1.743$$

$$\frac{p'}{p} = \frac{6.547}{7} = 0.935$$

The point corresponding to these values is shown at *B*, and it will be seen that it falls above the line of equal

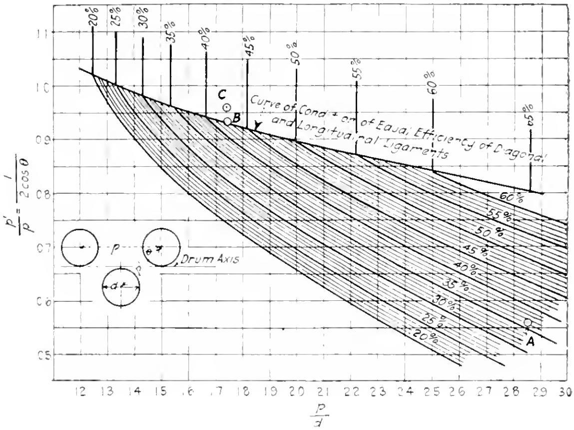

FIG. 12*a*

efficiency for the diagonal and longitudinal ligaments, in which case the efficiency is computed from formula *a*. Applying formula *a*, we have

$$\frac{7 - 4.0156}{7} = 0.426, \text{ efficiency of ligament, or 42.6 per cent.}$$

PAGE 48

PAR. 194. IN ADDITION TO THE REVISION PROPOSED IN THE MARCH SCHEDULE, ADD AT THE END OF PAR. 194 A NEW PARAGRAPH TO READ AS FOLLOWS:

Flanges of domes shall be formed with a corner radius measured on the inside, of at least twice the thickness of the plate for plates 1 in. thick or less, and at least three times the thickness of the plate for plates over 1 in. in thickness.

PAGE 50

PAR. 200. IN THE EIGHTH LINE CHANGE THE WORD "OR" AFTER "DRILLING" TO "OF."

PAGE 51

Par. 203. In Section *a* of Par. 203 in the fourth line, replace the words "by the formula" by the word "as."

PAGE 52

Par. 212. In Section *c* of Par. 212, in the first line, omit the word "internal."

In the last line of Section *c*, which is the last line of Par. 212, omit the letter "R."

PAGE 53

Par. 214. In the fifth line of Par. 214 change the word "shall" to "may," and in the sixth line omit the words, "but not less than 3 in."

PAGE 54

Table 4. In the second line under item *c* change "*c*" to "*b*."

Par. 220. In Section *c* of Par. 220 in the third line insert the word "as" before "given."

PAGE 61

Par. 239. In the new paragraph which is proposed in the March schedule to precede the example, change the words "butt and strap construction" to "butt and single or double strap construction."

PAGE 69

Par. 274. In the fifteenth line after the word "number" insert "and size."

PAGE 75

Par. 296. In the first line of the proposed addition to Par. 296, which appears in the March Journal, insert the following after the word "necessary":

> an exception may be made to the rule that the gage must be arranged so that it cannot be shut off except by a cock placed near the gage and

PAGE 76

Par. 299. In the seventh line, change the sentence following the word "face" to read as follows:

> See Par. 12 for exceptions. For pressures above 160 lb. per sq. in., cast iron shall not be used for boiler pressure parts except for fittings under 2 in. pipe size or equivalent cross sectional area. See Pars. 9 and 245

Fig. 18*a*. Omit the captions, "Bronze or Steel" and "Wrought Iron."

PAGE 79

Par. 332. Insert a sentence at the beginning of Par. 332 to read as follows:

> 332 Each boiler shall conform in every detail to these Rules, and shall be distinctly stamped with the symbol shown in Fig. 19, denoting that the boiler was constructed in accordance therewith.

In the eighth line of the revision of Par. 332 appearing in the March Journal, after the word "and" insert the word "he."

Replace the first two sentences of the second paragraph of Par. 332 by the following:

> Each boiler shall be stamped below the symbol as follows, with intervals of about one-half inch between the lines:
>
> 1. Name of state in which the boiler is built
> 2. State serial number of the boiler
> 3. Name of the manufacturer (and manufacturer's serial number if desired)
> 4. Installation number and name of the state in which the boiler is installed
> 5. Year put into service.
>
> Items 1, 2 and 3 are to be stamped at the shop where built.
>
> Items 4 and 5 are to be stamped by the proper authority at point of installation.

PAGE 80

Fig. 20. Revise Fig. 20 to read as follows:

To be stamped at shop where built	(State in which boiler is built)
	....................................STD
	(State serial number of boiler)
	....
	(Name of mfr.) (Mfr.'s serial No.)
	....
To be stamped in field	(Installation No.) (Name of state)
	....
	(Year put into service)
	....

PAGE 83

Par. 354. Omit Section *b* of Par. 354.

PAGE 85

Par. 361. In the ninth line insert the word "pipe" before "Connections."

PAGE 101

Par. 416. Omit Par. 416, and Figs. 26 and 27.

In accordance with its plan in eliminating as far as possible preventable diseases among workers in various industries, the United States Public Health Service of the Treasury Department has begun an investigation of the effect on the health of workers of pneumatic hammers as used in cutting limestone. Workers in this industry who use air hammers experience a temporary numbness of the fingers whenever the hand becomes chilled. The causes appear to be the higher vibration rate of the hammers when used in soft stone, and the tight and strained grasp which the workers have to use. Cold weather brings out the symptoms, but is not of itself a cause of the condition. By using a shank of larger diameter, which permits a more comfortable grasp by the worker, it is believed that a good deal of the strain on the muscles will be relieved. If the shank were enlarged by using a tight-fitting covering of asbestos, or some similar substance, the cold would not be intensified by the metal as at present and the handle would act as a shock absorber. (*Official Bulletin*, March 28, 1918, p. 11)

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE Secretary's letter this month might well be entitled, The Usefulness of a Technical Society in War. Notwithstanding that what follows is a routine activity, nevertheless, the Secretary doubts if many know of it. Our great ambition is to have the Society used.

Below is given a digest of only a few of the inquiries which were received in one week last month, accompanied by abstracts of the replies made and some typical letters of appreciation for our attention. Sometimes the information is secured by telephone, sometimes the inquiries are referred to the faithful members of the Society closest to hand, but when the urgency is not too great they are sent to committees to insure the replies' being of the most authoritative nature possible.

Your Secretary believes that the sum total of this prompt individual service is the best means of making the Society useful, and he is accordingly devoting special attention to such service, giving priority obviously to requests which are of a war nature.

One of the inquiries in this period was from a Government department for the names of manufacturers to make carpenters' stoppers, which was a somewhat unusual request, but regarding which we were able to secure considerable information through the courtesy of a member of the Society outside of New York and which we forwarded within five days.

Another, from a Government arsenal, was for information regarding a special type of gas mask for industrial use. This, like the foregoing inquiry, was a matter of urgency, so that the arsenal "might get immediate relief." We were able to supply this information within four days.

Still another inquiry from a Government department requested "at the earliest possible time" information regarding remedying a certain trouble with the machinery on a transport. This again was a matter which required us to get in touch with a member who had had special experience. We fortunately were able to and furnished the information the same day.

Another request was from a member for comprehensive information to assist him to prepare an important paper, as follows:

"If there are any permanent changes brought about by the war which necessitate greater activities in engineering research, what are these changes?

"How can the difficulties after the war be lessened by activities in research?

"What important engineering-research problems were brought about by the war and which can be published without injuring our interests?

"What phases of engineering research should be taken up at the present time?

"What engineering problems will be of utmost value to us during the reconstruction period?"

By referring this inquiry to our Research Committee, the member was able to secure valuable replies.

Also in this same week inquiries were received on such varied subjects as catalogues for aviation repair depots, to be used in the preparation of requisitions on purchase orders; sizes of gaskets for standard and extra heavy anges running from 20-in. to 60-in. pipe: all the recent articles relating to concrete-ship construction, soot cleaners, pulverized coal, small high-power water motors for experimental purposes, hardening of forgings of 0.40 to 0.50 carbon steel, baling presses, replacing a worn-out laboratory steam engine, motor-driven turbine blowers for a forced-draft proposition, etc. Some of these were answered direct by the Secretary or Editor assisted by our own extensive files and indexes, and some were referred to the Library Service Bureau, which every member should remember has special facilities for making bibliographical searches on all technical subjects.

Another set of numerous inquiries demanding urgent and special attention the same week were requests from Government departments and industries engaged in war work for men possessing special qualifications, to be commissioned or to serve in civilian capacities.

In this class came a request for nominations of specially qualified professional engineers for submarine duty, a request from an important Government board for men of the highest attainment in projectile fuses; a request for a whole staff of both technically trained and experienced engineers for officers or civilians in the construction and later the operation of nitrate and powder plants, a request for 75 men qualified for steel inspectors, and so on. We have furnished the names of several hundred specialists in one day and since our bureau was started have supplied over 3000 names. The members have responded splendidly to the request to fill out classification blanks, with the result that we are told that we have the most complete bureau in the United States.

On the other hand, we have on the average of three offers a day from members who desire to give their personal services or who have manufacturing facilities which they can devote to the service of the Government, and we make it our business to give prompt attention to these requests and refer them to the most likely departments requiring such services. The Engineering Council hopes soon to act as a clearing house for all the societies in the matter of providing men with special experience to fill particular positions in or out of the Government service.

In acknowledgment of our services we receive some very nice letters. In one recent acknowledgment they wrote: "Once more we are very grateful to you for your splendid work in submitting names of men for——"

We recently had a comprehensive request from the American Library Association to send our JOURNAL to the forty or more U. S. cantonment camps for the duration of the war. Upon the approval of the Library Committee this was promptly complied with, and the letters of acknowledgment we received afford wholesome reading. One camp librarian writes: "It is the heartiest sort of thanks that we extend to the Society for its complimentary subscription to its JOURNAL. Our table of technical periodicals is a mighty well patronized institution, and most welcome to it is your JOURNAL."

The Gage Committee has secured a signal triumph. Under its initiative the Society arranged a conference in Washington of the heads of all technical Government bureaus and made

the proposition developed at the Cincinnati meeting to have all gages certified in one place. The Bureau of Standards was designated by common consent as the place. Included in the Gage Committee's recommendation was the establishment of branch certification. We have the satisfaction of reporting the success of the certification and the establishment of a branch in New York and in the Engineering Societies Building.

The object of these reports is not, however, to produce a sense of satisfaction over performance however well accomplished. Rather we should be inspired to greater undertakings commensurate with our special abilities.

The Lord tells of some who had ten talents, some had five talents and of the man with one talent who did nothing even with his one talent!

In which group shall engineers place themselves?

There is only one way we can double our talents, namely, by using them. This nation has thrown itself unselfishly into the war. Write in to the Secretary what you can do more than you are doing, and what manufacturing facilities you have to offer. Also suggest more things that the Society can do. Come to the Spring Meeting in Worcester, June 4 to 7, and inspire all to greater endeavor.

Calvin W. Rice,
Secretary.

Council Notes[1]

At the meeting of the Council on March 15 the following members were present: C. H. Benjamin, *Vice-President,* in the chair, John H. Barr, W. F. M. Goss, R. H. Fernald, F. N. Bushnell, F. R. Hutton, A. M. Greene, Jr., D. S. Jacobus, Wm. H. Wiley, *Treasurer,* and Calvin W. Rice, *Secretary.*

Boiler Code Committee. Interpretations of the Boiler Code in cases Nos. 175, 185 and 186 were approved with slight modification and ordered printed.

War Activities Committees. The Secretary reported the following committees of the Society and joint committees on which the Society is represented, as being engaged in war activities:

- Committee on Engineering Resources
- Engineering Service Committee of the Engineering Council
- Committee on Vocational Training
- Committee on Machine Shop Practice
- National Defense Committee
- Gage Committee
- Naval Consulting Board of the United States
- National Research Council
- New York Military Engineering Committee.

Communications. A letter was read from Sir J. A. F. Aspinall, Honorary Member of the Society, announcing his election to the presidency of the Institution of Civil Engineers, and it was voted to extend congratulations and greetings to Sir John. The letter also mentioned the visit of Messrs. Hartness and Durand from our Society to the London Aircraft Standards Conference.

Adjournment was taken to meet in Philadelphia on April 23 on the invitation of the Philadelphia Local Committee, and to join with the Philadelphia Section at their regular meeting on this date. Following is the program arranged for the Council on this occasion:

[illegible] a. m. Council leave by motor car for Hog Island, guests of Resident Engineer, H. H. Esselstyn, member of the Publication Committee.

11.30 a. m. Council leave Hog Island by boat, as guests of Director of Bureau of Wharves and Docks, George S. Webster, for a trip up the river to Cramp's Shipyard.

12.15 p. m. Luncheon at Cramp's Shipyard, guests of L. F. Moody, Secretary of the Philadelphia Section.

1.15 p. m. Leave Cramp's Shipyard by automobile.

2.00 p. m. Council Meeting at Adelphia Hotel.

7.00 p. m. Dinner with the Philadelphia Section at Adelphia Hotel.

Calvin W. Rice,
Secretary.

[1] The April Journal went to press before the Council Meeting.

The Engineering Council's War Committee of Technical Societies

The War Committee of Technical Societies, of which Mr. David W. Brunton is chairman, was founded by the Engineering Council in July, 1917, and represented at the time of its formation the four founder societies. The Committee was formed for the purpose of stimulating members of the various technical societies into giving consideration to the matter of the invention of war apparatus, with the object of assisting the Army and Navy. As a definite means of effecting this object, the Committee was given the work of procuring problems—especially difficult problems—from the Army and Navy for presentation to the membership of the societies for solution.

For several months the Committee has been coöperating actively with the Naval Consulting Board, and now has offices and a meeting room in the New York office of the Naval Consulting Board, 15 Park Row. The Committee now has the following membership:

American Society of Civil Engineers:
Nelson P. Lewis, Major James M. Boyle
American Institute of Electrical Engineers:
Harold W. Buck, A. S. McAllister
American Society of Mechanical Engineers:
A. M. Greene, Jr., R. N. Inglis
American Institute of Mining Engineers:
David W. Brunton, Edmund B. Kirby
American Gas Institute:
Dana D. Barnum, E. C. Uhlig
American Electrochemical Society:
Joseph Bijur, Dr. Chas. A. Doremus
Illuminating Engineering Society:
Louis B. Marks, Preston S. Millar
Mining and Metallurgical Society of America:
Christopher R. Corning, George C. Stone
American Society of Refrigerating Engineers:
Henry Torrance, F. E. Matthews
American Institute of Chemical Engineers:
Charles F. McKenna, Frank E. Dodge
American Chemical Society: (Coöperating)
Dr. Chas. Baskerville, W. D. Richardson

For the past several months the Committee has been working energetically along these lines and has received from governmental departments problems of importance which have been passed on to various trained specialists, and in many cases information of great value has been received and turned over to the Government. Also through this Committee many of the largest and most important experimental and research laboratories of the country have offered their services to the Government and are now carrying on experimental work for the Government, which work has been apportioned to them by the Committee.

In connection with the above the Committee is now super-

intending tests and experiments for various departments of the Army.

One of the most pleasing features of the work in this connection has been the exhibition of intense interest and energy on the part of the various specialists in making tests and experiments for the Government. These men and these laboratories have given freely of their services for this purpose without any cost whatever, and have rendered services which would have cost the Government under ordinary circumstances large sums of money.

The value of the work of this Committee is now so well recognized that a prominent Ordnance officer has been assigned to the War Committee, so that complete and continuous contact may be effected with the Ordnance Department.

Another and most important function of the Committee is to assist members of the technical societies to develop their inventions, and to bring these inventions to the attention of the proper governmental authorities so that valuable inventions may be made effective in the shortest possible time. On account of the connection of this Committee with the Naval Consulting Board, abundant funds are available for testing out any idea or invention which appears to be promising.

On account of the fact that additional technical societies are now represented on the Committee over and above the four founder societies, the Committee now represents technical societies having a total membership of approximately 45,000 technically trained men, distributed as follows:

American Society of Civil Engineers	8600
American Institute of Electrical Engineers	7525
American Society of Mechanical Engineers	8800
American Institute of Mining Engineers	5500
American Gas Institute	1600
American Electrochemical Society	1600
Illuminating Engineering Society	1250
Mining and Metallurgical Society of America	310
American Society of Refrigerating Engineers	410
American Institute of Chemical Engineers	300
American Chemical Society (Coöperating)	9000

R. N. Inglis.

Special Service by the Journal

Arrangements have been made whereby The Journal of our Society is to render a special engineering-data service to the recently organized Research Information Committee of the National Research Council.

The purpose of this committee, as announced in the April number, is to gather and distribute to the various departments of the Government technical and scientific information, the results of investigation and research, and confidential advice from all available sources. The committee has headquarters in the rooms of the National Research Council, 1023 Sixteenth Street, Washington, and branch offices at the American Embassies in London and Paris. The technical adviser of the committee at the central office in Washington is Dr. Graham Edgar, formerly professor of chemistry at the University of Virginia.

The service which The Journal is rendering has developed as a result of the review of engineering periodicals which it has published for several years, and for the conduct of which a department has been built up at Society headquarters for scanning and reviewing the periodicals which come to the library from all parts of the globe. Abstracts are made of important articles appearing in journals of all languages, for publication in The Journal of the A.S.M.E., and copies of these are transmitted to Washington, together with more extended abstracts when required, translations of special articles, photostatic prints of articles and engravings, lists of titles appearing in the technical press, etc., as may be necessary to meet the demands of the Research Information Committee and the Government departments which it serves.

Power-Plant Inspection

The United States Fuel Administration have advised us that they are about to take a census of the power plants of the country with a view to listing principally information regarding their equipment and methods of operation. They state that the census will be similar to that taken by the Committee on Industrial Preparedness of the Industrial Plants of the Nation, and similarly will cover all the states of the Union. It is planned that the inspections shall be repeated at approximately regular intervals of several months each. The work will be done under the supervision of each state. As the Society coöperated in this previous work, it has been requested to offer similar service to the Fuel Administration for the new census. The census taking will consist in filling in on special forms, which will be provided, certain data called for.

If all will coöperate, such work can be done at the expense of only a fraction of the time of each member. *Volunteers* for such service are requested to communicate with the Society immediately for further information.

John Fritz Medal for J. Waldo Smith

On Wednesday, April 17, the John Fritz Medal was awarded to J. Waldo Smith, Mem.Am.Soc.M.E., chief engineer of the Board of Water Supply, New York, for "achievement as engineer in providing the City of New York with a supply of water" as a result of the construction of the Catskill Aqueduct. The meeting for the award was held in the Engineering Societies Building. The presentation was made by Ambrose Swasey, Past-President Am.Soc.M.E., who told Mr. Smith that he had accomplished one of the most remarkable engineering feats in history. In accepting, Mr. Smith praised his associates and subordinates, and said they had enabled this work to be accomplished by aiding in every problem which arose.

Encouraging Report from Major Gilbreth

Many inquiries have been received at Society headquarters regarding the health of Frank B. Gilbreth, who was taken critically ill while in the service at Fort Sill, Oklahoma. It is a pleasure to report that Major Gilbreth has so far recovered that he has been able to make the journey to Washington, D. C., where he will remain for several weeks in the Walter Reed hospital to receive treatment for rheumatism. Mrs. Gilbreth advises that as soon as his health has improved to the point where he can have "sick leave" he will return to his home at Providence, R. I., for final convalescence.

Opportunity for A.S.M.E. Women

The Woman's Auxiliary of the American Institute of Mining Engineers now has headquarters in the ladies' reception room on the ground floor of the Engineering Societies Building, New York. This will be used as a war-relief work room for the preparation of comforts for the engineer regiments. The members of the Woman's Auxiliary will be glad to have any of the ladies of the families interested in The American Society of Mechanical Engineers call at the headquarters and join with them in the very helpful work which they are undertaking.

SPRING MEETING PROGRAM

Tuesday, June 4

10:00 a.m. Opening of headquarters and registration at Hotel Bancroft
12:30 p.m. Luncheon for Sections Delegates and Council
2:00 p.m. Council Meeting
2:00 p.m. Meeting of Research Committee and Flow Meters Sub-Committee
8:00 p.m. Addresses of Welcome by Mayor Pehr G. Holmes, Past-President Ira N. Hollis, and R. Sanford Riley, President, Worcester Chamber of Commerce. (*Hotel Bancroft*)
Address by Charles G. Washburn on The Growth of an Industrial City
Reception and Dance

Wednesday, June 5, New England Day

10:00 a.m. Business Meeting (*Worcester Polytechnic Institute*)

FIRST NEW ENGLAND SESSION

The Small Industry in a Democracy, George H. Haynes
The Textile Industry in Relation to the War, J. E. Rousmaniere

10:30 a.m. Visit to Crompton and Knowles Loom Works. Special invitation to ladies
12:30 p.m. Buffet Luncheon (*Polytechnic Institute*)
1:00 p.m. Visit to plant of Royal Worcester Corset Company. Luncheon served. Special invitation to ladies
2:00 p.m. Sections Conference
2:00 p.m. Simultaneous Sessions (*Polytechnic Institute*)

Second New England Session

Papers will be presented upon subjects relating to New England's industries under war conditions, including: Converting a Factory for Munitions Manufacture; Fire Protection; Training Labor for Shipbuilding; Oil Fuel in New England Power Plants

General Session

Foundry Cost and Accounting System, W. W. Bird
The Public Interest as the Bed Rock of Professional Practice, Morris L. Cooke
Moisture Reabsorption of Air Dried Douglas Fir and Hard Pine, and the Effect on the Compressive Strengths, Irving H. Cowdrey
A High-Speed Air and Gas Washer, Lieut. J. L. Alden
Investigation of the Uses of Steam in the Canning Industry, J. C. Smallwood

Industrial Safety and Workmen's Compensation Session

This session will be in charge of the Sub-Committee on Protection of Industrial Workers

4:00 p.m. Tea and Reception at Tatnuck Country Club
8:15 p.m. General War Session. (*Hotel Bancroft*)

The general theme of this session will be: How the Engineering Societies Can Assist in the Procurement Program of the Government. Some major topics to be discussed are: Ordnance and Ships for the Navy Department; Munitions for the Army; Aircraft Material

Thursday, June 6

10:00 a.m. Simultaneous Sessions (*Worcester Polytechnic Institute*)

General Session

Efficiency of Gear Drives, C. M. Allen and F. W. Roys
Self-Adjusting Spring Thrust Bearing, H. G. Reist
Air Propulsion, Morgan Brooks
The Elastic Indentation of Steel Balls under Pressure, C. A. Briggs, W. C. Chapin, H. G. Heil
Electric Heating of Molds, Harold E. White
Stresses in Machines When Starting or Stopping, F. Hymans (*To be read by title only*)

Fuel Session

An Investigation of the Fuel Problem in the Middle West, A. A. Potter
Topical Discussion on Fuel Economy. (Arranged for by the Fuel Conservation Committee of the Engineering Council)

Vocational Training Session

A discussion of The Boston System for Vocational Training

1:00 p.m. Luncheon (*Norton Company's Plant*)
2:30 p.m. Paper upon the results of a questionnaire upon housing, issued to leading industrial firms
4:00 p.m. Inspection of the Norton Company's community housing and garden projects
7:00 p.m. Dinner (*Worcester Country Club*)
8:30 p.m. Illustrated Lecture. Harvard's Contribution to Astronomy, Dr. S. I. Bailey. Dancing

Friday, June 7

9:00 a.m. Automobile Trip to Camp Devens, via Clinton Dam; Lunch at Camp Devens; Continuation of Trip to Concord and Lexington and return via the Wayside Inn

FEATURES OF THE SPRING MEETING

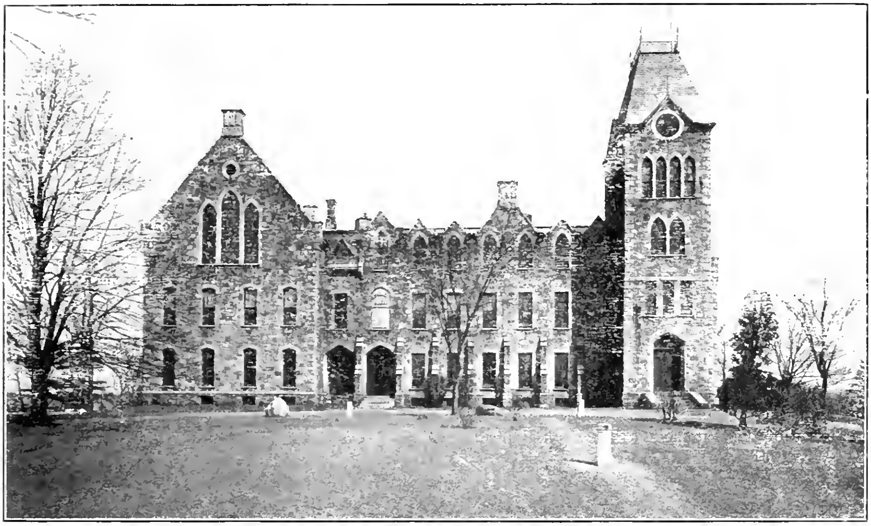
Worcester, Mass., June 4 to 7, 1918

THE coming Spring Meeting, like the two previous meetings, will be primarily a convention for conference on war problems, to which the engineers of the country, almost as a unit, are now giving their thought and attention.

It has been the usual custom at these Spring Meetings to have one or more sessions under the direction of the engineers in the city where the meeting is held, but in this instance the scope of the local representation has been broadened, and one whole day will be given over to the several Local Sections of the Society in New England, and the Providence Engineering Society, with papers on the work of the industries of New England in connection with the war.

On the evening of the same day, Wednesday, June 5, there will be a session, with addresses by representatives of the United States Government, on How the Engineering Societies Can Assist the Procurement Program of the Government in respect to ordnance, aircraft, ships, mobilization of labor, quartermasters' supplies, etc. On Thursday there will be a topical discussion on Economy in the Use of Fuel, arranged by the Fuel Conservation Committee of the Engineering Council, which will present the consensus of the experience of many of the fuel engineers of the country to whom questionnaires have been sent asking for definite data. Another session pertinent to the times will relate to vocational training, based on the Boston system, at the four principal technical schools of that city, under the direction of the War Department. Five hundred men are to be trained at Wentworth Institute and large numbers at the other schools.

On the afternoon of Thursday there will be an inspection of the model community for workmen of the Norton Company, at Worcester, with a discussion of housing problems based on a questionnaire issued to a large number of firms throughout the country. Besides these special features, there will be two general sessions for the presentation of technical papers.



Boynton Hall, Worcester Polytechnic Institute, Containing the Offices of the President. Several Sessions will be Held at the Institute, where all Members will be Welcomed

Entertainment Features

This is to be an outdoor convention with every opportunity for enjoyment of the natural beauty of the New England country, by means of automobile trips and entertainment at two country clubs at Worcester. Tea will be served on Wednesday afternoon at the Tatnuck Country Club, and on Thursday evening there will be a dinner at the Worcester Country Club, followed by a lecture by Dr. S. I. Bailey on Harvard's Contribution to Astronomy.

Two excursions have been planned for Wednesday, with special thought for the ladies' entertainment, though members and guests are cordially invited. The first of these trips is a visit in the morning to the Crompton and Knowles Loom Works, where their weave room and factory will be inspected and their many interesting and fancy looms shown in operation. The plant of the Royal Worcester Corset Company will be the scene of the afternoon's activities. After luncheon, at the plant, an inspection trip will be made to see how the Royal Worcester corsets are manufactured.

The various professional sessions will be so disposed that all day Friday will be free for automobiling, when a trip is planned to the cantonment at Camp Devens where lunch will be served; after which the trip will be continued to Concord, Lexington, and return by Wayside Inn.

Delegations from Nearby Cities

It is already arranged for delegations to attend from Boston, Providence and New York, and in the latter city a special

...ittee has been appointed which expects the attendance of ...any as 400 from New York and nearby points, representative of the New York membership. It is suggested that ... who can do so should go to Worcester by automobile, and ... the benefit of such the following instructions have been issued:

Automobile Routes to Worcester

From New York to Worcester take the main-traveled road to New Haven, 75 miles from Columbus Circle, New York. The route from New Haven leads to Hartford, Conn., by two roads: One through Middletown, 40.9 miles, which gives better views than the alternative route through Meriden, which is 37.1 miles. From Hartford the route goes to Springfield by Suffield, 26.9 miles; and from Springfield to Worcester the route is by Palmer, 51 miles, a total distance of 155.9 miles. Lunch can be secured at the Hotel Taft in New Haven, or at the Highland Court Hotel in Hartford, Conn.

From Albany to Worcester the route is from Albany to Troy, 8 miles, then to Williamstown, 36 miles, and from Williamstown over the Mohawk Trail to Greenfield, 42 miles; from there to Gardner, 39.4 miles, and then to Worcester, 28.2 miles, a total distance of 153.6 miles. A shorter route is from Albany to Pittsfield, 36 miles, then to Springfield, 56 miles, and from Springfield to Worcester, 51 miles, a total distance of 143 miles. However, the beauty of the shorter route is not to be compared with that of the other.

For Points West of Albany to Worcester the route will be shortened somewhat by turning off at Schenectady, going direct to Troy rather than to Albany.

Fred S. Sly, member of the Attendance Committee of New York, care of the *American Architect*, 243 West 39th Street, New York, will be glad to secure any special information for tourists that may be desired, or inquiries can be addressed to the Touring Bureau of the Automobile Blue Book Publishing Company, 243 West 39th Street, New York.

Hotels at Worcester

The headquarters for the convention will be at the Hotel Bancroft, and any who go by automobile are asked to call at the headquarters before putting up their cars so that they may be informed as to the garage which can best serve them at the time they call.

The leading modern hotels of Worcester are the Bancroft and the Warren. The minimum rates for these are as follows:

	Without Bath		With Bath	
	Single	Double	Single	Double
Bancroft	...	...	$2.75	$5.00
				6.00
				7.00
Warren	$1.50	$2.50	2.00	3.50

Other hotels, all of which have moderate rates, are the Bay State House, Franklin, New City, New Park and Pleasant. *Every person expecting to attend should secure his rooms well in advance, since hotels in Worcester, as in other cities affected by the business of the war, are having a large patronage and usually are crowded.*

While the Registration and Information Bureaus will be located at the Bancroft, several of the professional sessions will be held at the Worcester Polytechnic Institute, which will, in a measure, serve as a second headquarters where all will be welcome and where everyone in attendance is requested to make himself at home.

Fuel Session at Spring Meeting

As announced in the April Journal, on Thursday morning, June 6, there will be a session of the Spring Meeting at the Worcester Polytechnic Institute for five-minute presentations of data relating to fuel economy. This session has been planned by the Fuel Conservation Committee of the Engineering Council to assist the United States Fuel Administrator in his nation-wide campaign for fuel economy. Discussion is solicited upon the topics listed below, and all those who have studied the problems incident to the adverse fuel conditions of the past winter are invited to give the results of their experience in the form of brief written communications of from 100 to 1000 words each.

1 What Are the Economic Effects of Impurities in Coal?

Incombustible in fuel has a detrimental effect upon furnace operation out of all proportion to the percentage of refuse contained. It has been claimed that when coal contains 40 per cent of refuse it becomes valueless as fuel. Recent conditions have afforded opportunities for interesting observations in this connection. What has been your experience?

2 To What Extent Is Fuel Oil Likely to be Used as a Substitute for Coal?

Information is desired as to present use, advantage found, probable available supply, etc.

3 How Can Soft Coal Be Burned Without Smoke in Marine Boilers?

The avoidance of smoke would decrease the radius of visibility of our ocean carriers by many miles and greatly reduce their liability to attack by submarines. If efficiency is improved incidentally it means much more than the mere coal saving.

4 What Are the Possibilities in the Direction of the Utilization of Anthracite Wastes?

What success have you had in burning anthracite slack or culm? Do you mix it with soft coal, and in what proportions? What sort of grate do you use and what is your practice with regard to thickness of fire, draft, rate of combustion? Can the mixture be burned in a stoker?

5. What Instruments Are Useful and Desirable in the Boiler Room as Aids in Saving Coal?

What class of equipment has been of the most value to you and how?

6 What Is Essential to the Economical Operation of Hand-Fired Boiler Furnaces When Using Soft Coal?

Helpful hints as to firing methods, front or side; frequency of firing; management of dampers; cleaning; etc.

7 To What Kinds of Plants and Coals are the Different Types of Mechanical Stokers Respectively Adapted, and What Is the Limiting Factor to Their Use in the Small Plant?

Can we agree upon the type of fuel to the combustion of which each type of stoker is best adapted? How large must a plant be to warrant the use of a mechanical stoker?

8 What Experience Have You Had in the Use of Wood as Fuel? To What Extent Is Wood Available as a Fuel?

The coal shortage has occasioned the use of wood fuel in many unwonted places. Accounts of experience that will be helpful are solicited.

9 What Coal Economies Can Be Effected in Residence Heating?

He who could make one ton of coal do the work of two during the past winter, not only conserved the coal for his neighbor and saved his own money but was comfortable when he might have otherwise been cold. How can it be done?

10 What Coal Economies Can Be Effected in the Small Steam Plants?

Plants which are not sufficiently important departments of their industries to warrant expert supervision and are too small to support real engineers waste a lot of coal and steam in the aggregate. What are the principal sources and methods of waste and how can they be avoided and corrected?

11 What Experiences Have You Had With the Storage of Coal?

AMONG THE LOCAL SECTIONS

THE semi-annual conference of Sections' representatives will take place during the Spring Meeting at Worcester. The members of the Council will meet at luncheon with the Sections' delegates, and addresses will be made by President Main and Dr. Hollis.

The Council made its second visit to a Section on April 23, when it held its April meeting at Philadelphia, and in the evening attended the meeting of the Philadelphia Section. During the forenoon the members of the Council had an opportunity to make a special inspection of Hog Island.

Secretary Rice is to go on a somewhat extended trip which will take him to a large number of the Sections. Coming during this crisis in the history of our country, it is felt that this visit by the Secretary will do an inestimable amount of good in correlating the war activities of the Society through the medium of its Sections.

A noteworthy example of the effectiveness of coöperation between Sections and Student Branches was had at New York on April 9. The New York Section turned its April meeting over to the Metropolitan Student Branches located at Columbia University, New York University, Polytechnic Institute of Brooklyn, and Stevens Institute of Technology. Two sessions were held and a buffet supper served between them. About 300 persons attended the afternoon session, over 400 partook of the supper and over 650 were present in the evening. The program included eight speakers, the supper, entertainment features, souvenirs and light refreshments after the evening session.

The Committee in charge of the arrangements consisted of Messrs. J. Gorso, Columbia University, H. Lowenstein, New York University, N. N. Wolpert, W. Sumner and M. Bernner, Brooklyn Polytechnic Institute, and L. V. Aquadro and H. E. Beaven, Stevens Institute of Technology.

Section Meetings

ATLANTA

April 9. Mr. W. G. Eager, Assoc.Mem.A.S.M.E., gave an interesting address on The Effect Upon Fuel Economy of Different Arrangements of Baffles in Boiler Tubes.

CECIL P. POOLE,
Section Secretary.

BALTIMORE

The Section has been recognized by the Fuel Administration and one of its committees, composed of Messrs. Henry Adams, A. E. Walden, W. W. Varney, and A. G. Christie, has been coöperating with the Fuel Administration and the Liberty Loan Committee, in regard to the third Liberty Loan. At the present time the A.S.M.E. Section in coöperation with the Engineers' Club is taking prominent part in engineering matters of public interest in Baltimore.

A. G. CHRISTIE,
Section Secretary.

BIRMINGHAM

February 22. At a joint meeting of the Alabama Technical Association with the A.S.M.E. Section, C. B. Davis, Mem.Am.Soc. M.E., presented a paper on the subject of Fuel Conservation and Increased Production. A résumé of the paper showed:

1 That the possible conservation of coal will be a saving of approximately 126,370 tons annually if the necessary methods are adopted at the various plants as suggested:

2 That the possible saving by making all coke in by-product ovens will be approximately 689,750 tons of coal annually:

3 That an output of approximately 2,000,000 tons annually can be obtained at a cost of approximately $2,000,000 for the initial investment and requiring in the way of new labor 3500 men

4 That the present output will be increased by 5,340,000 tons at an initial cost of $3,840,000 and showing an annual saving of $1,770,000; and

5 That a further increased production could be made by more efficient transportation and utilization of the Warrior and Alabama Rivers for transportation.

Mr. F. G. Cutler, Mem.Am.Soc.M.E., called attention to conditions in Alabama for the saving of fuel and showed that the tendency is to use water power and surplus gas from blast furnaces and by-product ovens. The use of low-pressure-turbine-driven generators in the Birmingham district alone would affect a saving in excess of that quoted by Mr. Davis. He ventured the prediction that within a few years the consumption of coal under boilers for the production of power would be practically eliminated.

Mr. H. M. Gassman, Mem.Am.Soc.M.E., pointed out the difficulty of opening up new mines and modernizing existing mines on account of the large amount of capital invested; and also the difficulty of obtaining equipment and securing labor necessary to operate them. He suggested that a conservation campaign be waged and industrial plants consuming more than five tons per day be urged to conserve coal.

Mr. H. S. Geismer claimed that the opening of new mines would not be feasible at the present time, due to the shortage of labor in the district, which is not sufficient to work the present mines to their full output per man employed. He pointed out that electrification would not be an immediate remedy, due to the difficulty of obtaining deliveries of mining machinery and other equipment. Also that the mines best adapted for that type of equipment have already been electrified. He sugested a campaign to make the miners themselves realize that they alone could increase the output and said that almost without exception the miners are not working full time nor do they seem to realize their duty to the Government in the present crisis.

Mr. M. J. Lide, Mem.Am.Soc.M.E., pointed out the losses due to inefficient steam engines, where more waste could be accounted for than at the boilers. Special stress was laid on the question of instructing labor.

The subject was also discussed in its various phases by Samuel Stewart, R. A. Lee, W. F. Wilcox, G. N. Mitcham, J. T. McKenzie and B. B. Ross.

The following resolution was adopted unanimously:

> RESOLVED. That it is the sense of the Alabama Technical Association to urge operators to run their plants with the greatest possible regard for the conservation of fuel and also that employees and operators coöperate to run mines and industrial plants continuously and at the best possible output, making such sacrifices as are necessary with a view of furnishing a maximum production, and thereby very materially assisting our Government in bringing the war to a prompt and successful conclusion.

April 25. Mr. J. W. Moore, Assoc.Mem.Am.Soc.M.E., delivered an interesting paper on The Gas Producing Plant of the American Cast Iron Pipe Company.

W. L. ROUECHE,
Section Secretary.

BOSTON

April 30. At a joint dinner of the Engineering Societies of Boston Mr. Alfred D. Flinn, Secretary of the Engineering Council, delivered an address on the work of the Engineering Council. Further details regarding the meeting will be published in a succeeding issue of THE JOURNAL.

W. G. STARKWEATHER,
Section Secretary.

BUFFALO

March 27. Prof. D. S. Kimball, Mem.Am.Soc.M.E., delivered a lecture on Water Powers of the Pacific Coast, which was not only of unusual technical interest, but was illustrated with many lan-

tern slides of great beauty, since practically all of the power plants described were situated at places of unusual scenic grandeur.

April 3. At a special meeting of the Buffalo Engineering Society, Mr. N. Boland, of the Beyers Manufacturing Company, delivered an illustrated lecture on The Manufacture of Wrought Iron Pipe, showing the manufacture of wrought iron pipe from pig iron to the finished product.

April 10. At the seventh general meeting of the Buffalo Engineering Society, Eskil Berg, of the General Electric Company at Schenectady, gave a talk on The Recent Development of Propelling Machinery for War and Merchant Ships. The speaker brought out the recent advances in the use of the steam turbine with electric drive for propulsion of war and merchant vessels, showing that high efficiency, at various speeds can be obtained with the electric drive, and pointing out its advantages over the gear drive for large power installations. The water rate per b.hp. of turbine installations with electric and gear drive was compared with that for the same type of ship equipped with reciprocating engines and it was shown that the large turbine installations are more economical than the best types of reciprocating engine installations, particularly when two or three speeds must be maintained for long periods as mentioned above. Mr. Berg's close connection with the war vessels now being built made it possible for him to bring out the latest and the expected future developments of the turbine equipment upon which much work and study has been put.

April 17. Under the auspices of the Electro-Chemical Section, Mr. Oliver C. Ralston, Metallurgist for the Hooker Electro-Chemical Company, Niagara Falls, gave a talk on Recent Advances in Western Non-Ferrous Metallurgy.

E. B. NEIL,
Section Secretary.

CHICAGO

April 22. At a joint meeting of the Chicago Sections of the A.S.M.E., A.I.E.E. and the Mechanical and Electrical Sections of the Western Society of Pennsylvania, C. F. Kettering, Mem. Am.Soc.M.E., delivered an interesting paper on The Automobile Power Plant.

A. L. RICE,
Section Secretary.

CINCINNATI

March 21. A joint meeting of the Engineers' Club of Cincinnati and the A.S.M.E. Section which included two sessions, was held at the Literary Club rooms. The afternoon session was opened by Henry Ritter, Mem.Am.Soc.M.E., with a paper on Shop Kinks, in which he dealt with the subject of shop management in general.

Prof. John T. Faig, Mem.Am.Soc.M.E., delivered a paper on The Economic Use of Coal by Communities which was illustrated by lantern slides. The waste inherent in the present methods of utilizing coal in cities of the Middle West was pointed out. A by-product coke-oven plant handling 7000 tons of coal per day and producing coke, gas, tar, ammonia and benzol was discussed from a business and economic standpoint and the economic advantage of the process and the addition to the raw materials of the country were shown.

Mr. C. U. Carpenter, Mem.Am.Soc.M.E., opened the evening session with a lecture on The Training of Women for Industry. He told of the training of thousands of women of no experience in mechanical lines for the manufacture of time fuses for Russian shrapnel. These women were recruited from all walks of life, and were absolutely ignorant of production work on machines, but by organizing a school apart from the shops, and selecting instructors very carefully, it was found possible to train the women so that they were not only capable of making the parts of these time fuses within the necessary degree of accuracy, usually within one thousandth of an inch, but it was also found possible to train them to give production superior to that secured from men. One of the interesting features of this experiment in the use of women on machine work was the fact that it was found possible to produce time fuses in enormous quantities that met every requirement of rigid inspection without any particular difficulty. In the course of the discussion which followed, Mr. Carpenter brought out the point that his method of organization and teaching was as directly applicable to men as to women, and in his opinion operatives should always be taught in a school separate from the shop. He believed this to be productive of much better results. Operatives whose skill does not appear to increase are withdrawn from the works and put in the school again, under careful instructors who study their defects and attempt to correct them.

The meeting proved to be a great success and there were over 150 persons in attendance.

JOHN T. FAIG,
Section Secretary.

CONNECTICUT SECTION

Bridgeport Branch

April 24. The afternoon session was a general get-together meeting in order that those attending the dinner and evening session might be better acquainted. After the dinner, which took place in the Stratfield Hotel, the evening session opened with a patriotic address by Judge Pullman, of Bridgeport. The following gentlemen also addressed the meeting: Clinton E. Woods, of the Woods-Keller Company, on Factory Accounting as a Bill for Controlling Production; Harry E. Harris, Chairman of the Joint Gage Committee, A.S.M.E. and S.A.E., on Facilitation of War Production by Practicable Manufacturing Allowances; and Wm. R. Webster, Mem.Am.Soc.M.E., on Intelligent Specifications and Inspection as a Factor in Production Increase.

R. W. ELLINGHAM,
Branch Treasurer.

Meriden Branch

The Meriden Branch of the Connecticut Section met April 19th at the Chamber of Commerce Hall. Mr. F. C. Bolton, Tool Engineer at the Meriden Plant of the Colt Patent Fire Arms Manufacturing Co., gave a very interesting description and demonstration of the Browning Machine Rifle. The rifle upon which America is placing great dependence in the great struggle against autocracy, weighs 15 lb. and contains 110 parts. Its bullets travel through the barrel at a rate of 2700 ft. per second and it can fire twenty shots in from two to two-and-a-half seconds. In test, 20,000 shots were fired at high speed without a miss-fire. A feature of the gun is the magazine which holds 20 cartridges and which the operator drops to the ground by releasing a spring. Eight hundred rounds of ammunition can be carried by one man. Another feature of the gun is the ability to fire a single shot or a number of shots according to the will of the operator. Admission was restricted to invited guests, the attendance being slightly over 180.

C. N. FLAGG, JR.,
Branch Secretary.

New Haven Branch

April 16. Mr. George A. Orrok, Mem.Am.Soc.M.E., delivered an interesting paper on Internal-Combustion Engines. He described the development of the aeroplane engine and told of some very interesting recent experiences in connection with the new Liberty motor. This motor is entirely different from the one designed last summer. Comparisons of a number of makes of aeroplanes were made and the speaker stated that in his opinion it is not desirable to manufacture motors under 2.7 lbs. per h.p. Motors which have been developed in the last few months have been strengthened so that they have a working capacity of from 140 to 200 hours. Mr. Orrok said the Germans are now making motors for aeroplanes using the Diesel engine type.

The internal combustion engines made for other purposes were described and it was pointed out that the farmer of the present day depends exclusively upon these to do all of his chores, from tilling the soil to milking the cows, lighting his home, and delivering his produce to the markets.

Among those who joined in the discussion were Messrs. F. R. Low, Editor of Power, Professor L. P. Breckenridge, Professor E. H. Lockwood, S. F. Jeter, Secretary of the Hartford Branch, C. K. Decherd, Chairman of the Meriden Branch. Mr. H. B. Sargent presided.

Mr. Orrok addressed the Student Branch at Yale University in the morning on the same subject.

E. H. LOCKWOOD,
Branch Secretary.

ONTARIO

March 25. At the second annual meeting of the Joint Committee of Technical Organizations, to which the members of all of the engineering societies were invited, special emphasis was made by Col. David Carnegie to the need of training the directors and distributors of production, in order that the whole resources of the country might be devoted to the maximum state of efficiency toward winning the war. He made a strong appeal for greater industrial education in Canada. Preparation of the child for industrial training, he declared, was the immediate need of the day, and urged upon his hearers the importance of strong action, either in the form of direct representations to the Government, or separate action by the organization, or by individuals. He also proposed the establishment of national and district trade boards.

Mr. W. E. Segsworth, Administrator of the Vocational Branch, Military Hospitals Commission, gave a most comprehensive and interesting explanation of the gigantic work undertaken in connection with the Invalided Soldiers' Commission.

Soldiers placed in factories by the commission are situated only after each individual case is thoroughly investigated as to the man's adaptability, and these men are continually looked after by officers, usually engineers having wide experience in all branches of industry, to keep this labor from being exploited.

In closing, Mr. Segsworth impressed upon his audience the need of improved measures for the training and care of blind soldiers.

CHESTER B. HAMILTON, JR.,
Section Secretary.

PHILADELPHIA

March 27. At a joint meeting of the Engineers' Club of Philadelphia and the A.S.M.E. Section, Dr. S. W. Stratton, Director of the U. S. Bureau of Standards, presented a paper on The Relation of the Bureau of Standards to the War, in which he dealt with the scientific work of the Government. Following the lecture a patriotic address was made by Corp. Frank Street, of the British Strathcona Horse.

April 23. After a visit to the A.I.S.C. at Hog Island and the Wm. Cramp Ship and Engine Building Company's yards, the Council of the Society attended a dinner meeting of the Section held at the Adelphia Hotel. The subject of the meeting was Shipbuilding and was discussed from all points of view. A more detailed account of the meeting will appear in a succeeding issue of THE JOURNAL.

JOHN P. MUDD,
Section Secretary.

PROVIDENCE

March 27. Under the auspices of the Municipal Engineering Section, Frederick N. Connet, Mem.Am.Soc.M.E., delivered an illustrated lecture on Recent Developments in the Use of the Venturi Meter.

March 28. A social meeting of the Efficiency Section was held at which W. H. Harriman, of the Universal Winding Company, related his personal experiences in engineering in Mexico.

March 29. At a joint meeting of the Chemical Section of the Providence Engineering Society and the Rhode Island Section of the American Chemical Society, Frederick H. Franklin, connected with Saunders & Franklin, delivered an illustrated lecture on The Metallography of Cast Iron.

April 9. Following a business meeting W. A. Kennedy, Mem. Am.Soc.M.E., presented a paper on Bronze and Its Uses.

April 10. The subject of the meeting held under the auspices of the Power Section was Mill Heating and Lighting.

JAMES A. HALL,
Correspondent.

ST. LOUIS

March 29. After the regular monthly dinner Dr. Isaac Lippincott, associate professor of economics at Washington University, delivered one of the most interesting addresses ever presented before the Section, on Economic Reconstruction After the War.

R. L. RADCLIFFE,
Section Secretary.

SAN FRANCISCO

March 20. An informal dinner was tendered Prof. George F. Swain, Mem.Am.Soc.M.E., and Past-President of the Am.Soc.C.E., by the joint Sections of the A.S.C.E., A.I.M.E., A.I.E.E. American Chemical Society, and the A.S.M.E. Among the many speakers of the evening were the following: P. M. Downing, chief engineer of the Pacific Gas & Electric Company, who delivered a talk on Interconnection of Power Plants; Prof. D. M. Folson, who presented the subject of Fuel Oil Saving; Mr. Max Thelen, President of the State Railroad Commission, who spoke on the subject of War Activities of the Railroad Commission, and Professor Swain, who selected the vitally important subject of National Issues of Today. The meeting was presided over by Prof. C. D. Marx, of Leland Stanford, Jr. University.

C. H. DELANY,
Section Secretary.

Student Branch Meetings

NEW YORK STUDENT BRANCHES

As has been customary for the past few years the Metropolitan Student Branches at Columbia University, New York University, Polytechnic Institute of Brooklyn and Stevens Institute of Technology, again held their Joint Meeting. This year, however, the meeting was held jointly with the New York Section on April 9th, and included an afternoon session, a buffet supper and an evening session. The meeting was a great success and the attendance as large as the well attended sessions of the Annual meetings. The Student Committee in charge of the arrangements are to be congratulated upon their enterprise. The Committee included: Messrs. J. Gorso, Columbia University, H. Lowenstein, New York University, N. N. Wolpert, W. Summer and M. Berner, Polytechnic Institute of Brooklyn, and L. V. Aquadro and H. E. Beaven, Stevens Institute of Technology.

The convention, for such it was in fact, established a new record, which, in these times of depleted student ranks owing to student service in the war, reflected great credit on the enterprise and ability of the committee having the meeting in charge. The entire affair was held on the fifth floor of the Engineering Societies' Building, the capacity of which was taxed to the utmost. Four hundred students and local members attended the "pay-as-you enter" buffet dinner and nearly 700 were present at the evening session.

At the afternoon session talks were given by several engineers as follows:

WANTED: CAPTAINS OF INDUSTRY AFTER THE WAR, M. H. Avram, President Slocum Avram Slocum Company.

WHAT THE ENGINEER HAS DONE FOR THE WAR, F. R. Low, Editor of *Power*.

ENGINEERING PROBLEMS OF THE WAR, Geo. A. Orrok, Consulting Engineer.

CERTAIN PHASES OF ENGINEERING EDUCATION, Prof. Collins P. Bliss, New York University.

ORGANIZATION AND THE RELATION IT BEARS TO ENGINEERS, Charles Whiting Baker, Consulting Engineer and Consulting Editor of *Engineering News-Record*.

At this session an interesting announcement was made by Prof. Bliss of a new educational plan proposed by New York University for greater co-operation between the University and the industries. The plan contemplates 20 scholarships of \$25,000 each, in return for which special opportunities in research work and in the use of the facilities of the University will be available. Classes are to be divided into two sections which will alternate every other term between the University and the co-operating industry.

In the interval following the dinner the audience was highly entertained by "Jack" Armour of *Power*, and during the evening selections were given by the orchestra from Polytechnic Institute of Brooklyn. The evening programme comprised the following addresses:

THE YOUNG ENGINEERS IN THE PRESENT CRISIS, Past-President Ira N. Hollis.

CERTAIN ACCOMPLISHMENTS OF THE NAVY IN THE WAR, Lieut. B. F. Hart of the Brooklyn Navy Yard.

THE WAR IN THE AIR, G. Douglas Wardrop, Editor *Aerial Age;* illustrated by lantern slides and moving pictures.

UNIVERSITY OF CALIFORNIA

February 28. Mr. Domonoske, instructor of machine design at the University, gave an interesting account of student life and work at the University of Illinois.

March 14. At this meeting two papers were presented, one on The Gnome Engine, by E. K. Schulze, and the other on The Spillway of Calavaras Dam, by Prof. J. N. Le Conte.

March 28. Mr. H. L. Reich presented a paper on Power Plants of the San Joaquin Light & Power Co., and Prof. B. F. Raber gave an interesting talk on Dynamometers.

LLEWELLYN BOLTER,
Branch Secretary.

CARNEGIE INSTITUTE OF TECHNOLOGY

April 10. Mr. W. G. Chester, of the Babcock & Wilcox Company, gave an illustrated talk on the various types of boilers manufactured by this company, dealing mainly with the features of the land and marine types. The inability of makers to standardize their product, he said, was a result of the demand for many different types, each especially adapted to peculiar conditions of operation. The difference in design between the ordinary and the marine boiler due to the requirements for compactness and high capacity was clearly shown by many excellent slides.

H. D. KRUMMEL,
Branch Secretary.

UNIVERSITY OF CINCINNATI

March 1. Mr. Fosdick, civil engineer for the W. G. Franz Co., gave a talk on the Dixie Terminal Building to be erected in Cincinnati, which is to serve as an office building for the Kentucky Green Line and the new rapid transit cars. Problems which a contractor has to overcome to fill his contract involving the solving of labor troubles, the advantages and disadvantages of concealing steam piping, considerations in laying out heating systems, problems of sanitation, deciding upon materials of construction, laying out decorating and lighting effects, placing exits properly so as to avoid standing lines during rush hours, and the question of getting supplies such as building materials, were all accurately traced.

March 21. Mr. Hinkle, who has been speaking at the various army cantonments throughout the country, delivered an intensely interesting talk on The Evolution of the U. S. Army Rifle, and exhibited a collection of twenty guns showing those used by our army and navy from the Revolutionary War to the present time. The working principles of the most important types of small arms, the methods of loading the gun and the various forms of ammunition used were discussed in detail.

C. L. KOEHLER,
Branch Secretary.

KANSAS STATE AGRICULTURAL COLLEGE

March 7. Mr. J. B. Marcellus, of the Portland Cement Manufacturing Association, who is at present carrying on research work at the college, gave a talk on Cement, in which he traced the methods of manufacturing cement from the early days.

March 28. Mr. Walter Miller, of the Shop Practice Department, gave a talk on Military Training in Switzerland tracing the various steps and processes as developed by the Swiss Government in training their fighting forces.

I. O. MALL,
Branch Secretary.

UNIVERSITY OF KANSAS

April 4. A plan of reporting on articles published in technical magazines was tried out and the articles appearing in a recent issue of *Power* on the Tamarack Power Plant and on Training Engine Room Crews for American Crews were fully discussed.

H. C. VAN HOUTEN,
Branch Secretary.

LEHIGH UNIVERSITY

April 5. A lecture on Modified Springfield Ammunition as made by the Union Metallic Cartridge Co., was delivered by Mr. B. P. Lander. Specimens tracing the shell from the brass disk to the completely drawn shell were shown and the speaker also told how bullets are cast and jacketed.

Mr. L. J. Jenkins gave a lecture on the Brief History of the Development of the Steam Engine, tracing its progress from the time of its invention by Watt to the present date.

Mr. E. L. Forstall delivered a paper on the Work of the American Army Engineers in France, showing how the corps has been enlarged and how it has been working in France to provide efficient transportation for the American Army.

N. DMYTROW, JR.,
Branch Secretary.

LOUISIANA STATE UNIVERSITY

February 14. The following officers were elected for the ensuing year: E. C. Freeland, chairman; J. Lobo, vice-chairman; C. R. Strattman, secretary; O. A. Wing, treasurer.

A brief address was given by E. C. Freeland, explaining the advantages of joining the A.S.M.E. upon graduation.

March 26. Following the business meeting a very interesting and instructive talk was given by Mr. Piller, Chief Electrician of the Standard Oil Co., on The Operation of Large Gas Engines as used by the Standard Oil Company of Louisiana.

C. R. STRATTMAN,
Branch Secretary.

UNIVERSITY OF MAINE

February 13. Two papers were presented, one by Mr. Chapin on Static and Dynamic Balancing and the other on Motion Study as Applied to War Cripples, by Mr. Russell.

A. MASON RUSSELL,
Branch Secretary.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

April 5. Prof. Charles M. Allen, of the hydraulic engineering department, delivered an illustrated lecture on the Use of Dynamometers and Water Brakes in Tests on Power Plants.

By exhibiting rating curves of circular, Government and other rating stations, which coincided almost identically, he pointed out that in rating current meters a circular station is exactly as accurate as any other. Then by means of capacity-power and gate-opening power curves, it was shown that enough water was wasted in using full gate opening in preference to 0.85 of full-gate to run a separate unit, and that a loss of many dollars resulted.

S. H. CALDWELL,
Branch Secretary.

MICHIGAN AGRICULTURAL COLLEGE

March 7. Mr. Livingston, of the Reo Motor Car Company, presented a paper on Accident Prevention, pointing out the need of definite methods of preventing accidents. Progress has been made in this regard by the installations of mechanical safeguards, the inspection of plants periodically, by placing definite responsibility upon certain employes, and by the organized effort among foremen.

H. M. SASS,
Branch Secretary.

UNIVERSITY OF MISSOURI

March 8. Prof. H. Wade Hibbard, recently engaged in Washington making plans for organizing and making efficient certain departments relative to the war, gave a lecture on Organization Engineering. The underlying principles of efficiency management together with charts used in that work were explained in detail, such as charts representing the organization of an American railway, principle, production, procedure, and production-delays charts.

March 26. Mr. K. K. King presented a paper on The Design of Motor-Truck Engines for Long Life, discussing the factors which go to make up longevity. Methods used in designing rods, wrist-pin bushings, pistons, cylinders, camshafts, valves and other sundry parts were thoroughly described and the methods of

lubrication-splash feed, pressure feed, and splash-pressure feed traced as to their relative merits.

J. W. Baldwin,
Branch Secretary.

OREGON AGRICULTURAL COLLEGE

March 27. Mr. M. L. Granning, instructor in machine-shop practice, gave a lecture on the Construction of a Modern Shrapnel Shell. Incidentally he pointed out the changes which have been made in several large industrial shops which now devote all or a majority of their time to the production of munitions.

Neal K. Ford,
Branch Secretary.

STEVENS INSTITUTE OF TECHNOLOGY

March 4. Arrangements were reported regarding inspection trips. Election of officers for next semester took place on account of the senior class graduating in April, two months prior to regular graduation. This has been possible because of the war schedule which has been in effect since September. The following officers were elected: George H. Spencer, chairman; Harry E. Beaver, vice-chairman; Lincoln V. Aquadro, secretary-treasurer.

L. V. Aquadro,
Branch Secretary-Treasurer.

UNIVERSITY OF WISCONSIN

March 14. Professor Callan gave an account of his recent trip to Europe as a member of a committee sent by the United States Shipping Board. His talk covered briefly his trip over, a new gas engine using exhaust gas to generate steam which is used behind the piston, ship industries of England, gun and submarine building, aeroplanes and air raids.

Wm. Mantonya,
Branch Secretary.

WORCESTER POLYTECHNIC INSTITUTE

Died in France, February 15, 1918, E. W. Jones, United States Aviation Service, Student Member of Worcester Polytechnic Institute Branch.

March 8. At a meeting to which the members of the Civil Engineering Society were invited the subject of The Determiuation of Water Waste in American Cities by Pitometer Methods was presented by Edward S. Cole, Mem.Am.Soc.M.E. Mr. Cole used charts of pumpage against time to demonstrate how large an amount of water had to be furnished a city's mains, even during the night and on Sundays, and by subtracting from this the amount probably used during these periods, a surprisingly large quantity was still left which could only be accounted for as wastage. He then described two types of apparatus for measuring the flow in city mains, one being the Deacon meter and the other the pitometer, with photographic recording attachments. Several experiences in tracing out wastage in metropolitan districts were related. The method of isolating a district by shutting off communicating mains was shown, together with the telltale drops in the pitometer record.

H. P. Fairfield,
Branch Secretary.

YALE UNIVERSITY

March 15. J. Douglas Wardrop, member of the A.I.E.E. and editor of the *Aerial Age*, delivered a most instructive illustrated lecture on The War in the Air, tracing the history and development of the various types of aeroplanes and aircraft in general and pointing out the speeds, cruising radius, carrying capacity and horsepower of the various English, American, French, Italian and German planes.

The importance now and in the future of aeroplanes adapted to both war and peace service, showing their suitability to submarine detection and aerial photography, was also touched upon.

Wm. Rogers Herod,
Branch Secretary.

ROLL OF HONOR

Ashley, Edward E., Jr., Captain, Signal Corps, U. S. Army.

Barlow, Frederic C., Captain, Engineers, 10th Regiment Forestry, U. S. R., American Expeditionary Force, France.

Berg, H. J., Lieutenant, Aviation Section, Signal Officers' Reserve Corps, Ellington Field, Olcott, Texas.

Brock, Clarence A., Field Hospital No. 34, Camp Greenleaf, Medical Officers' Training Camp, Fort Oglethorpe, Ga.

Burrage, Charles W., U. S. Naval Air Service.

Carpenter, Charles I., Approvals Section, Finance Department, Equipment Division, Signal Corps, U. S. Army.

Carter, Clifford R., Equipment Division, Aviation Section, Signal Corps.

Christen, A. B., First Lieutenant, Signal Corps, American Expeditionary Force, France.

Clendon, G. W., Officers' Training School, Artillery Section, Camp McClellan, Ala.

Cooke, Eugene L., Coast Artillery Corps, U. S. Army, Fort Monroe, Va.

Dent, John A., Captain, Ordnance Department, National Army, American Expeditionary Force, France.

Duffy, Frank J., Lieutenant-Colonel, 103rd Regiment Engineers, Camp Hancock, Augusta, Ga.

Ericson, Edward O., First Lieutenant, Ordnance Officers' Reserve Corps.

Flowers, Alan E., Captain, U. S. R., Signal Corps, Land Division, Radio Development.

Fuller, Floid M., Lieutenant, U. S. Naval Reserve Force, Assistant Naval Inspector of Ordnance.

Gilmore, John W., Captain, Coast Artillery Corps, U. S. Army.

Gremmel, Henry F., Second Lieutenant, Ordnance Officers' Reserve Corps.

Hartzell, Earl F., Co. A, 319th Engineers, Camp Fremont, Cal.

Heilmann, Carl A., 303rd Engineers, American Expeditionary Force, France.

Hoskins, Stephen P., Candidate, Third Officers' Training Camp, Camp Lee, Va.

Hubbard, Guy, Ordnance Department, N. A., Ordnance Training School, Dartmouth College, Hanover, N. H.

Hunter, Charles F., Major, Ordnance Department, N. A., Frankford Arsenal, Philadelphia.

Johnston, A. Langstaff, Jr., Lieutenant, Inspector of Machinery, U. S. Navy.

Keet, Clarence T., Second Lieutenant, Engineers, N. A., 5th Co., Engineer Reserve Officers' Training Camp, Camp Lee, Va.

Kulling, O. W., Headquarters Co., 315th Infantry, Camp Meade, Md.

La Fon, Alphonse, First Lieutenant, U. S. R., 18th Co., Coast Artillery Corps, Fort Hancock, Sandy Hook, N. J.

Lindblom, Herbert R., Corporal, Co. E., 301st Engineers, Camp Devens, Mass.

Logan, Lloyd, Private, Co. D, 1st Quebec Regiment, Canadian Expeditionary Force.

Lohmann, Alfred P., Lieutenant Commander, Naval Reserve Flying Corps.

McJilton, John P., First Lieutenant, 65th Engineers, Camp Meade, Md.

Mabbott, H. C., First Lieutenant, Coast Artillery Corps, Fort Totten, New York.

Maury, Dabney H., Lieutenant-Colonel, Construction Division, Quartermaster Corps, N. A.

Miller, Fred J., Major, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Rock Island, Ill.

Montgomery, H. M., Major, Quartermaster Corps, N. A.

Morrill, Guy L., Sergeant, Quartermaster Department, U. S. Army.

Morse, E. R., First Lieutenant, Ordnance Officers' Reserve Corps, 6th Ammunition Train, 6th Division, Headquarters, Camp McClellan, Ala.

Newman, W. C., Warrant Gunner, U. S. Naval Reserve Force, Boston Navy Yard, Charleston, Mass.

Parks, Burritt A., Captain, Engineer Officers' Reserve Corps.

Reckford, John King, Lieutenant, Junior Grade, Naval Reserve Flying Corps.

Robertson, Elroy C., Equipment Division, Signal Corps, U. S. Army.

Rosenfield, Harold, Aviation Section, Signal Corps, Reserve Officers Training Camp.

Royal, James M., Second Lieutenant, Aviation Section, Signal Officers Reserve Corps, School of Military Aeronautics, M. I. T.

Ruth, R. W., Chief Storekeeper, U. S. Naval Reserve Force, assigned to Washington, D. C.

Sauerwein, George K., Captain, Ordnance Officers' Reserve Corps.

Schaller, Alwin L., Captain, Ordnance Department, N. A., Aberdeen Proving Ground, Aberdeen, Md.

Summers, Daniel, Captain, 28th Engineers (Quarry), N. A., Camp Meade, Md.

Taylor, John E., 31st Engineers (Railway Operation Regiment), U. S. Army.

Wadsworth, J. Frederic, Co. A, Machine Gun Battery, No. 313, Camp Lee, Va.

Walbridge, Arthur H., Ensign, U. S. S. *Arkansas*.

Widdicombe, R. A., Major, Quartermaster Corps, U. S. Army.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by May 16 in order to appear in the June issue.

CHANGES OF POSITION

Charles F. Merrill, formerly assistant chief draftsman of the Draper Corporation, Hopedale, Mass., has entered the engineering department of the James Hunter Machine Company, of North Adams, Mass.

Dwight K. Bartlett, until recently assistant treasurer of the Builders Iron Foundry, Providence, R. I., has become associated with the Electro Bleaching Gas Company, and the Niagara Alkali Company, with headquarters at New York City.

Harry K. Fox has assumed the duties of engineer of tests of the Chicago, Milwaukee and St. Paul Railway, Milwaukee, Wis. He was formerly connected with the Western Maryland Railway Company, Hagerstown, Md., in the capacity of chief draftsman of the motive-power department.

Erford J. Peebles has resigned his position of production engineer for the New Haven Clock Company, New Haven, Conn., to take a position on the staff of C. E. Knoeppel and Company, New York. He has been assigned to industrial engineering duties for the Emergency Fleet Corporation, U. S. Shipping Board, Washington, D. C.

Elroy C. Robertson, formerly with the Frantz Premier Company, Cleveland, Ohio, is now associated with the New York District Equipment Office, Signal Corps, U. S. A.

D. B. Clark, formerly superintendent of the shell department of the American Brake Shoe and Foundry Company at Erie, Pa., is now general superintendent of the Watervliet Arsenal, Watervliet, N. Y. Mr. Clark has charge of the entire production of this plant which is the largest and oldest arsenal in the United States.

William C. Fisher, formerly affiliated with the Griscom Russell Company, New York, has become associated with the American Agricultural Chemical Company, Liebig Works, Carteret, N. J.

R. A. Wentworth, until recently superintendent of the Saco Lowell Shops, Lowell, Mass., has assumed the duties of assistant superintendent of the U. S. Cartridge Company, of the same city.

R. H. Dunbar, formerly mechanical engineer with the American Tube and Stamping Company, Bridgeport, Conn., has accepted a position with the Providence Engineering Corporation, of Providence, R. I.

John E. Lovely, formerly connected with the Vermont Farm Machine Company, Bellows Falls, Vt., has become associated with the Jones and Lamson Machine Company, Springfield, Vt.

V. J. Mohler has assumed the position of factory manager with the Moore Motor Vehicle Company, with offices at Danville, Ill. He was formerly identified with the C. J. Tagliabue Manufacturing Company, of Brooklyn, N. Y., as assistant manager of factories.

Henry S. Isham, until recently affiliated with the New York Railways Company, New York, as draftsman, has entered the employ of Ford, Bacon and Davis, of New York, in the capacity of assistant engineer.

Stanley Munson has left the engineering department of the Proctor and Gamble Manufacturing Company, Kansas City, Kan., to become chief engineer for Kirkman and Son, Brooklyn, N. Y.

E. Burton Smith, formerly affiliated with the Westinghouse Lamp Company, Bloomfield, N. J., has entered the employ of the International Arms and Fuze Company, Inc., of Bloomfield, N. J.

Alfred L. Acuhler, recently with the Southwark Foundry and Machine Company, of Philadelphia, Pa., has accepted a position with the Cresson-Morris Company, of the same city, in the engineering department.

Julius G. Hayman, formerly superintendent of the Chattanooga Gas and Coal Products Company, Alton Park, Tenn., has become affiliated with the Union Carbide Company, Niagara Falls, N. Y.

J. Gordon Sparkes, recently associated with Robert D. Johnston, Jr., patent attorney of Birmingham, Ala., has joined the staff of the Standard Scientific Company, New York.

Alfred D. White has assumed the duties of chief operating engineer of the Standard Oil Company, of Brooklyn, N. Y. He was recently affiliated with the Economy Engineering Company, as manager of the New York office.

Edward J. Blanchard, formerly assistant engineer with R. Martens and Company, Inc., New York, has become associated with Young, Corley and Dolan, Inc., of the same city.

Frank L. Glynn, until recently secretary of the Wisconsin State Board of Industrial Education, Madison, Wis., has become affiliated with the Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y.

Charles Foster has been appointed, by the Board of Water and Light Commissioners, general superintendent of the Public Utilities under their control, and assumed his new duties on April 1. He was formerly manager of the St. Paul office of Charles L. Pillsbury Company.

ANNOUNCEMENTS

Roy W. Gifford, affiliated with the Massey-Harris Company, Ltd., Toronto, Ont., Canada, as superintendent of the munitions department, has assumed the position of superintendent of the Toronto Works of the same company.

E. Edmund Jackson, of the H. W. Johns-Manville Company, is resident engineer in charge of roofing construction at the new Federal Shipbuilding Company's plant at Kearny, N. J.

Harry Himelblau, mechanical engineer with the American Steam Conveyor Corporation, Chicago, Ill., has been transferred from the Chicago office to the New York office of the organization and is now employed in the capacity of sales engineer.

Dwight S. Cole has discontinued his office as a consulting mechanical engineer and patent attorney, in Grand Rapids, Mich., due to failing health and sight. His plans for the near future include outdoor work of such a nature as may be helpful toward regaining normal health. He will continue to reside in Grand Rapids, and keep somewhat in touch with his former lines of activity.

Major H. M. Montgomery, Quartermaster Corps, N. A., has been relieved from his present station and duties and will proceed to Jeffersonville and take his station at that place for duty as construction quartermaster for the quartermaster storehouse to be located at that place.

Malcolm Curry, general engineer of the American Thread Company, Holyoke, Mass., Kenneth B. Millett, assistant general engineer, formerly at Willimantic, and A. C. Richardson, of Holyoke, are now located at the head office of the company in New York, to which has been transferred the office of the general

engineering department of the American Thread Company, which was formerly at the Merrick Mills at Holyoke.

Wilbur M. Bosworth has recently had patented steel center constructions, or underframes, which are being used by the Norfolk Southern Railroad Company in reinforcing old freight cars. Mr. Bosworth, who was formerly mechanical engineer with the Norfolk Southern Railroad Company, has become connected with the engineering department of the Under-Feed Stoker Company, Chicago, Ill.

Francis A. Vaughn, senior member of the firm of Vaughn & Meyer, consulting engineers of Milwaukee and Wausau, and Charles L. Pillsbury Company, consulting engineers of Minneapolis and St. Paul, has been engaged by the School of Engineering of Milwaukee as business manager and director of engineering and industrial relations.

James Brakes, Jr., has assumed the position of electrical tester for the Commonwealth Edison Company, of Chicago, Ill.

Harry A. Goalwin has become associated with Dr. Frederick Lester Stanton, of New York, and the two will act as consulting orthodontists and medico-technical engineers. Besides his work of developing this new field of mechanical engineering, Mr. Goalwin will continue his medical course at the College of Physicians and Surgeons, Columbia University, New York.

Arthur L. Roberts has been transferred from the position of mechanical engineer of the Lehigh Valley Railroad Company at South Bethlehem, Pa., to that of master mechanic of the same company, at Coxton, Pa.

Sidney Diamant, formerly at the De Mant Tool and Machine Co. of New York, is continuing his tool and manufacturing business under the firm name of the Diamant Tool and Manufacturing Co., Newark, N. J.

Louis Illmer has become associated with the American Whaley Engine Company, Boston, Mass., in the capacity of mechanical engineer.

William E. Hamilton has become connected with the Standard Parts Company, of Cleveland, Ohio.

Henry D. Jackson, formerly of Timothy W. Sprague and Henry D. Jackson, consulting engineers of Boston, Mass., has joined the organization of Monks and Johnson, engineers and architects, of Boston, Mass., as power engineers, in charge of their power plant and heating work.

Stevens Institute of Technology, Hoboken, N. J., recently conferred the honorary degree of doctor of engineering upon J. Waldo Smith, who was chief engineer on the new Catskill Aqueduct recently turned over to New York City to increase the water supply.

Sidney G. Walker has been appointed vice-president of the Manufacturers' Mutual Fire Insurance Company, Providence, R. I., with which firm he was formerly connected in the capacity of engineer.

NECROLOGY

EDWIN A. STEVENS

Col. Edwin A. Stevens, member of the famous old American family which in Revolutionary days practically founded what we now know as the city of Hoboken, died on March 8, 1918, in Washington, D. C., where he was serving as a field officer of the Emergency Fleet Corporation.

He was born in Philadelphia on March 14, 1858, and attended St. Paul's School, Concord, N. H., later entering Princeton University, from which he was graduated in 1879 with the degree of A.B. In 1905 he was given the degree of Doctor of Engineering by the Stevens Institute of Technology, founded in 1868 by his father, Edwin A. Stevens.

He served as Park Commissioner and as Tax Commissioner of New Jersey and also served on the commission which settled the long-standing boundary dispute between the states of New York and New Jersey. For some time he was also Commissioner of the New York and New Jersey Palisades Interstate Park. In 1880 he was made adjutant of the old Ninth Regiment of New Jersey, and later served on the staff of Governor Ludlow. His appointment as Colonel of the Second Regiment came still later, and he was commander of the regiment for six years. In 1911 he was appointed Commissioner of Public Roads by President Wilson when the latter was Governor of New Jersey. In 1914 he was reappointed by Governor James F. Fielder and served until 1917, when the laws were changed and the management of the road department was taken out of the hands of a commissioner and invested in a commission of eight members.

Colonel Stevens designed the *Bergen*, the first screw-propeller ferryboat. This vessel is still in commission and operates between Hoboken and New York. That invention marked a signal departure in the construction of such vessels and one which proved so satisfactory that all other ferry lines adopted the patent. He had many other inventions of a mechanical nature to his credit. He was president of the Hoboken Ferry Company until 1896 when it was taken over by other interests, later being acquired by the Lackawanna Railroad.

A little more than a year ago Colonel Stevens was appointed a member of the State Highway Commission by Governor Edge.

He was a member of the Society of Naval Architects and Marine Engineers and of the Institute of Naval Architects in Great Britain. He became a life member of our Society in 1889.

Lucius Lawrence Moses

LUCIUS LAWRENCE MOSES

Lucius L. Moses was born on November 26, 1868, in Marcellus, N. Y. He was educated in St. John's Military School, Manlius, N. Y., and later took a special shop course in Cornell University.

From 1889 to 1893 he served his apprenticeship with the Phenix Foundry & Machine Co., Syracuse, N. Y. He then entered the employ of the Paragon Plaster Co., as construction and operating superintendent, having complete charge of the engineering work and of the manufacturing. His next position was with the Clyde Gas & Electric Co., Clyde, N. Y., as treasurer and general manager. Mr. Moses held chief engineer's papers for ocean-going vessels, and from 1901 to 1909 he was in the service of the United States Government in that capacity. In 1909 he became associated with Henshaw, Bulkley & Co., San Francisco, Cal., as construction engineer, and later became consulting engineer in charge of the engineering work of the Hallidie Machinery Co., Seattle and Spokane, Wash. At the time of his death he was practising as a consulting engineer in Seattle.

Mr. Moses was a member of the Marine Engineers' Association, Seattle and San Francisco. He became a member of the Society in 1912. He died on October 15, 1917.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JUNE 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 90.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by June 10, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about June 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

ENES, JAMES T., Designer, Tennessee Coal Iron & R. R. Co., Birmingham

SIRNIT, JOHN A., Designing & Electrical Engineer, Alabama Power Co., Birmingham

California

CHURCHMAN, WILLIAM H., Superintendent of Pumping Stations, East Bay Water Co., Oakland

COOLEY, DICK M., Sales Engineer Howe Scale Co., San Francisco

Connecticut

LANEY, FRANK B., Representative in Field of M. M., International Silver Co., Meriden

POST, JOHN D., Assistant to Chief Engineer, The American Brass Co., Ansonia

SHUBERT, GEORGE E., Supervisor of Barrel Department, Remington Arms U. M. C. Co., Bridgeport

WOLFE, JOHN A., Power Superintendent American Brass Co., Ansonia

District of Columbia

BRANTLEY, PERLE P., Mechanical Draftsman, Gun Division Trench Warfare, Washington

HENSZEY, JOSEPH W., Captain, Ordnance Reserve Corps, Inspection Division, Washington

MESSER, THOMAS H., Captain, Engineer R. C., U. S. A., Washington

Illinois

DOWNING, LLOYD E., Efficiency Engineer, Troy Laundry Machine Co., Chicago

NICHOLLS, ALFRED T., Designer, Ar[illegible] & Co., Motive Power Department, Chicago

Kansas

SCHOOLEY, SYLVESTER S., Instructor in Electrical Engineering, University of Kansas, Lawrence

Maryland

HUSS, HENRY, Second Vice President, New York & Hagerstown Metal Stamping Co., Hagerstown

TALIAFERRA, JOHN C., Member of Executive Committee of Directors, Continental Can Co., Baltimore

Massachusetts

HILDRETH, CHARLES I., President and General Manager of Whitcomb-Blaisdell Machine Tool Co., Worcester

JACKSON, P. ANDREW, Mechanical Engineer, American Writing Paper Co., [illegible]

KNOWLES, LUCIUS J., President, Crompton & Knowles Loom Works, Worcester

MELLOR, ALFRED S., Expert Tool Engineer, Cambridge

MURRAY, JAMES A., Commission Merchant, Fall River

TURNER, FRANK A., Chief Engineer, Becker Milling Machine Co., Hyde Park

Michigan

THOMPSON, WILLIAM G., Mechanical Engineer, The United States Graphite Co., Saginaw

Missouri

MUDD, HERBERT K., Assistant Engineer, Steam Engineering Department, Union Electric Light & Power Co., St. Louis

SHANE, LOUIS, Commander, U. S. N., Acting Inspector of Machinery, Busch Sulzer Diesel Engine Co., St. Louis

New Jersey

CAMPBELL, E. GORDON, Superintendent of Construction, Public Service Electric Co., Engineering Department, Newark

HYDE, THOMAS E., Works Manager & Assistant Secretary Huhn Mfg. Co., Arlington

New York

CHAMPION, CHARLES H., Engineer Manager Electrical Division, H. Boker & Co., Inc., New York

FOSTER, CHARLES L., Engineer, Ossining Chemical Works, Ossining

JOHNSON, GEORGE A., Consulting Hydraulic Engineer and Sanitary Expert, New York

McNULTY, ALLEN C., Designing Mechanical Engineer, Westinghouse, Church, Kerr & Co., New York

MALCOLM, GEORGE H., Assistant Construction Manager, Otis Elevator Co., New York

PARSONS, [illegible] H., Engineer, Construction Department, American Locomotive Co., Schenectady

RUSSELL, JOHN M., Engineering Assistant, New York Telephone Co., New York

WHITE, [illegible] J., Superintendent of Machinery, [illegible] Co., New York

Ohio

AMOLD, [illegible] B., Sales Engineer, Hooven, Owens, Rentschler Co., Cincinnati

CARREL, J. WALLACE, Vice President and General Manager, The Lodge & Shipley Machine Tool Co., Cincinnati

THOMPSON, W. G., Inspector, Youngstown Sheet & Tube Co., Youngstown

Oklahoma

BURRELL, THOMAS L., Manager, Burrell Eng. & Con. Co., Oklahoma City

Pennsylvania

BELL, FRANK B., President, Edgewater Steel Co., Pittsburgh

COLBURN, C. P., Major, Ordnance R. C., Officer in Charge and Superintendent Fuse Shop F. A., Frankford Arsenal, Philadelphia

CUSHING, SAMUEL D., Managing Director, John B. Semple & Co., Sewickley

DAVIS, LUTHER A., Production Superintendent, Standard Screw Co., Corry

JONES, CARL G., Transformer Engineer and Designer, Westinghouse Electric & Mfg. Co., East Pittsburgh

KEBLER, ELIOT A., President, Fawcus Mach. Co.; Special Representative, The Matthew Addy Co., Pittsburgh

PENROSE, CHARLES, Engineer, Executive Staff, Day & Zimmermann, Inc., Philadelphia

Tennessee

FISCHER, FRED W., Chief Engineer, Master Mechanic, Standard Knitting Mills, Knoxville

Washington

BRETHERICK, CLARENCE O., Mechanical Engineer, J. F. Duthie Co., Seattle

COX, ALLEN H., President and Manager, A. H. Cox & Co., Inc., Seattle

Wisconsin

DEVLIN, EDWARD C., President, Universal Machinery Co., Milwaukee

TESCHAN, WALTER F., President and General Manager, Milwaukee Concrete Mixer Co., Milwaukee

Canada

JENCKES, JOHN M., General Manager, Engineering & Machine Works of Canada, Ltd., Sherbrooke, Ontario

China

GAITHER, ROBERT H., Manager Engineering Department and Acting Agent, American Trading Co., Shanghai

Cuba

ANDERSON, ROBERT A., General Sales Manager, American Steel Co. of Cuba, Havana

LOMBARD, J. OSWALD, Senior Partner, Lombard & Co., Havana

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Massachusetts

GELINEAU, EMRIE E., Draftsman, The Lamson Company, Lowell

WASHBURN, EDWIN F., 1st Lieutenant, O. R. C., Watertown Arsenal, Watertown

Michigan
FASOLDT, Karl N., Heating and Ventilating Designer, Ford Motor Co., Detroit

Pennsylvania
HANDLOSER, Bertram F., Chief Engineer, Dilworth, Porter & Co., Inc., Pittsburgh
WILLIAMS, David G., Chief Engineer, Pennsylvania Trojan Power Co., Allentown

Wisconsin
CLARK, Edward S., Plant Manager and Engineer, De Pere Manufacturing Co., De Pere

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

District of Columbia
WILSON, Roger J., Computer in the Seacoast and Railway Mount Section, Engineering Bureau, Ordnance Department, Washington

Kansas
BOWMAN, George M., Senior Student in Electrical Engineering at University of Kansas, Lawrence

Maryland
RIDER, Albert L., Contracting Engineer, Albert L. Rider, Baltimore

New York
COLLINS, William, Assistant Engineer, Walter Kidde & Co., Inc., New York
FREAS, H. LeRoy, Mechanical Engineer, New York District for Elliott Co. of Pittsburgh, Pa., New York
GRIFFIN, Cecil M., Testing and Erecting, Alberger Pump & Condenser Co., New York
JAMISON, George S., Engineer, Underwriters' Bureau of the Middle and Southern States, New York
ROBINSON, Ralph L., Engineer, Salesman, Griscom-Russell Co., New York
RYAN, John A., Assistant Engineer, H. Boker & Co., Inc., New York

Ohio
ENGEL, Paul H., Lieutenant, O. R. C., Dayton

Pennsylvania
DUKE, Henry T., Equipment Specification Engineer, Ballinger & Perrot, Philadelphia

Porto Rico
CERECEDO, Javier H., General Manager, J. H. Cerecedo & Co., San Juan

FOR CONSIDERATION AS JUNIOR

District of Columbia
MALEY, Robert C., 2nd Lieutenant, Ordnance R. C., Washington
WALEN, Ernest D., Associate Physicist, Bureau of Standards, Washington

Florida
FRANKS, Norvin H., Material Agent, Ship Installing Yard for Emergency Fleet Corp., California Brick Co., Jacksonville

Illinois
BOLLING, John E., Chief Engineer, Drying Systems, Inc., Chicago
CHOATE, Donald H., 2nd Lieutenant, 332nd Field Artillery, Camp Grant

Maine
MARBLE, Gerald C., Proprietor, Skowhegan Monumental Works, Skowhegan

Michigan
MEISENZAHL, Julius A., Inspector A. and A.E., Detroit District Equipment Office, Engineering Department, Detroit

New Jersey
FEIST, Seymour, Production Engineer, Standard Aircraft Corporation, Elizabeth
FORD, Wendell B., Aeronautical Engineer, Aeromarine Plane & Motor Co., Keyport

New York
CONNOR, William B., President, W. B. Connor, Inc., New York
EVERETT, Russell W., Mechanical Engineering, Alberger Pump & Condenser Co., New York
IGLEHEART, George P., Ensign, U. S. Naval Reserve, Office of Superintending Constructor of Aircraft, Curtiss & Co., Buffalo
TYLER, Howard H., Testing Engineer, Alberger Pump & Condenser Co., Newburgh

Ohio
MADISON, Harry A., Naval Aviator, U. S. Naval Reserve Flying Corps, Cambridge

Pennsylvania
RAMAGE, Raymond W., Assistant to Production Engineer, Bethlehem Steel Co., Reading

Virginia
DEGLER, Howard E., Instructor in Mechanical Drafting and Science, Hampton Institute, Hampton

Wisconsin
HUTCHENS, Ralph W., Mechanical Engineer Gillette Rubber Co., Eau Claire

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

Canada
SMALLWOOD, R. L., General Sales Manager, Dodge Manufacturing Co., Ltd., Toronto

PROMOTION FROM ASSOCIATE MEMBER

Maryland
FELKER, George F., Major of Ordnance, National Army, Engineering Bureau, care Gunpowder Reservation, Baltimore

Tennessee
WILFERT, George, Captain Ordnance R.C., Army Inspector of Ordnance, Columbian Iron Works, Chattanooga

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

PROCESS INSPECTOR. Man should be capable of taking initiative in bettering conditions and methods of cartridge manufacture. Should be familiar with punch presses, drawing presses, and production on a large scale. Location, Massachusetts. 2596-A.

DIMENSIONAL INSPECTOR OF FINISHED COMPONENTS. Familiar with design and use of special gauges, verniers, etc. Location, Massachusetts. 2596-B.

BALLISTIC ENGINEERS to work on velocity and accuracy tests and data. Location, Massachusetts. 2596-C.

MAN conversant with shipping, tracing, and traffic management. Location, Massachusetts. 2596-D.

COMPETENT OFFICE MANAGER, capable of taking charge of, and disposing of, all office detail in plant. Location, Massachusetts. 2596-E.

All of the above preferably beyond draft age, or, if of draft age, outside of Class 1.

NUMBER OF MEN needed for duties in connection with the maintenance and operation of utilities, such as electric lighting, water supply, road construction, steam-heating plants, building repairs, etc. These men to be above draft age, and in addition to their technical knowledge, should be men who are capable of team work. 2604.

MEN WITH PRACTICAL PRODUCTION EXPERIENCE wanted as assistant superintendents. Those in late classification of draft considered. Location, New York. 2605.

ENGINEERS able to read and translate French, with some experience in the manufacture of steel and steel forgings. Men

[illegible] Location, New York City 2606.

PLANT ENGINEER, man of wide experience for work of exceedingly varied character. 2607 A.

ASSISTANTS TO OFFICERS IN CHARGE OF SHOPS. Men over draft age familiar with machine shop practices. 2607 B.

LUBRICATION ENGINEERS, qualified both in the theory and practice of the internal-combustion engine, as well as in the handling of lubricants, and the engineering side of lubrication. 2608.

CIVILIAN POSITIONS

SUPERINTENDENTS, ASSISTANTS, FOREMEN AND CHIEF OPERATORS. Chemical, electrical, electrochemical, gas, liquid air, refrigerating and mechanical engineers, all with operating experience. Staff of one hundred big men wanted by large industrial plant in Alabama engaged in important Government work. College men with technical training and familiar with cement, power, refrigerating, chemical, sugar refining and electric plants; operators experienced on mining and milling machinery, crushers, conveyors, compressors, furnaces, kilns, ovens. Competent men will be trained in the processes, paid good salaries during instruction, and given an attractive contract as soon as qualified. State age, nationality and experience. 088-E.

MAN WITH TECHNICAL TRAINING as mechanical engineer wanted in inventory and appraisal department of one of the eastern state commissions; one year or more experience in engineering work preferred. Some knowledge of accounting and of appraisal work desirable but not essential. Present engineering staff is small and good opportunity for advancement. Location, New Jersey. 0168 E.

STEAM PLANT SUPERINTENDENT for large paper mill in Canada. Engine room experience not necessary but technical education desirable. Salary commensurate with ability. 0169 E.

SUPERINTENDENT for boiler and machine shop employing about 100 men, building water-tube marine boilers; some engine work. Technical man about 35 years old with broad acquaintance and ability to handle men and actual experience in similar work. Exclusively Government contracts. Excellent opportunity for advancement. State age, nationality, salary, present employment, reference, and when available. Location, South. 0170 E.

ASSISTANT SUPERINTENDENT for outside erection work. Location, South. 0171 E.

CHECKER AND TWO MECHANICAL DRAFTSMEN on munition work, involving power plant equipment design, and handling machinery. Good opportunity for men willing to work hard on war work. Location, Delaware. 0172 E.

MECHANICAL ENGINEER with about five years' experience in power plant construction to act as assistant in connection with construction nitrate plant. Salary, $2,000. Should have deferred draft classification. Location Alabama. 0174 E.

MECHANICAL DRAFTSMAN experienced in power plant work for position in connection with construction nitrate plant. Should have deferred draft classification. Salary, $1,800. Location, Alabama. 0175 E.

INSTRUCTOR, elementary mathematics and mechanical drawing for apprenticeship school. Candidates should have had some technical training and shop experience and understand the handling of young men. Position offers excellent opportunities for advancement in the works and will pay an initial salary of $1200, or more, according to caliber of man. Location, Connecticut. 0176 E.

TIME-STUDY AND COST-WORK MAN, preferably about 27 years old, with actual experience in routine work for a machine shop doing work of a semi-standardized type, on large engines, not interchangeable; capable of setting times on large machine tools. Must be an American citizen. Salary about $30.00. Location, New York. 0177 E.

EXPERIENCED FACTORY PLANNING DEPARTMENT HEAD required by a New York company employing 2,000 men engaged in the manufacture of a variety of complicated electrical and mechanical apparatus. Applicant must have had at least five years' experience in tool design, routing, and dispatching. Excellent prospect open for the right man. State age, education, experience, salary required, and nationality. 0180-E.

FACTORY MANAGER. A well-known New York company employing about 1,800 men, engaged in the manufacture of a variety of electrical and mechanical apparatus, all covered by its own patents, is in need of an experienced factory manager capable of efficiently organizing and managing the factory department, which includes the following departments: welfare and employment, service and maintenance, planning and production, and a shop operating branch. Excellent opportunity. Write, stating age, education, experience, nationality, and other qualifications. 0181-E.

ASSISTANT CHIEF ENGINEER. A New York company employing about 2,000 men engaged in the development, design, and manufacture of complex electrical and mechanical apparatus for special purposes, requires an experienced assistant chief engineer capable of taking charge of mechanical design, standardization, and drafting, leaving the chief engineer free to devote himself to research, invention, and development. Applicant must be technical graduate with at least five years' mechanical designing experience. Excellent opportunity for an able man, position carries good salary, as well as the prospect of very interesting work and a broad future. State age, education, experience, nationality, and salary required. 0182-E.

DRAFTSMAN, with technical training and sufficient experience to enable him to lay out machinery in new plants, including the making of drawings, covering electric light and power systems. Permanent position. Prefer man with chemical plant experience, or one who has done drafting for consulting engineer. State fully qualifications and past experience. Salary $1,500 to start. Location, Southern Ohio. 0184 E.

MAN capable of taking charge of department employing about 100 men. Must thoroughly understand the bleaching, dyeing, sizing and calendering of cotton goods, a good handler of men. Position would pay about $35.00 per week to start and more after the man was able to demonstrate his ability. Location, near New York. 0185 E.

DRAFTSMEN of general mechanical experience, men of integrity reliability and industry, with experience in general drafting, design and layout work. State age, details of experience, salary expected and references. Location, Delaware. 0186 E.

BOILER MAN fully conversant with every detail of design and construction of steam boilers, particularly water-tube boilers. Must be willing to make an investment in a progressive boiler shop. Location, New Jersey. 0187 E.

FOUR OR FIVE TECHNICAL GRADUATES to take a standard apprenticeship course covering a period of two years in boiler shop. Location, New Jersey 0188-E.

DRAFTSMAN AND FIELD MAN. Young engineer with knowledge of anthracite colliery practice. Location, Pennsylvania. 0189 E.

PUBLIC SERVICE COMMISSION. Opportunity for several young technically trained men, preferably with some practical experience in mechanical or electrical engineering. Salary, $90.00 per month to start. Give particulars as to age, training, and experience. Location, New York. 0192-E.

SALES ENGINEER AND PURCHASING AGENT, preferably a man with experience in building line. Position requires man of caliber capable of doing purchasing for medium-sized factory and of handling the development of sales program. One not subject to draft or a late number in the draft. Preferably acquainted in and about New York. Headquarters, New York. 0194-E.

SALES ENGINEERS to represent a line of carefully selected power-plant specialties; sale involves a knowledge of their use and adaptation to power plants in general. Necessary that men have more than an outline knowledge of power-plant design, construction, and operation, in addition to ability and knowledge as salesmen. Prefer men with several years' experience as sales engineers. Location, Virginia. 0196-E.

YOUNG MEN, technically trained in mechanical engineering course, to enter engineering department of company manufacturing fluid meters and special equipment. Rapid advancement to outside power-plant engineering work. Location, Boston, Mass. 0197-E.

DRAFTSMEN for proposition department, in power-house and boiler-rooms, and in making estimates of costs, as an aid to sales department. Opportunities for young men of ability are exceptional. Important that men be conscientious and reliable. Location, New Jersey. 0207-E.

TRANSPORTATION ENGINEERS AND EXECUTIVES. Prominent truck manufacturer offers unusual opportunities for several mechanical engineers for organization and development work and to train for executive positions with owners of large truck fleets, the demand for which is only just beginning. The privilege of a short preparatory training at nominal pay is available. Write how qualified and salary expected. Location, New York State. 0208-E.

EVAPORATOR EXPERT. Engineer experienced in designing and selling of evaporating apparatus for large concern desirous of extending their business. Letter should contain detailed information as to past experience, qualifications, and salary expected. Location, New York State. 0210 E.

DRAFTSMAN acquainted with smelting work. Location, Texas. 0211-E.

SALES ENGINEERS for hand stoker. Will pay liberal commission on the gross sales price. Man should have a technical foundation and be familiar with combustion problems. Would expect man to spend two weeks

with organization to gather selling data, facts and operation of the stoker, thoroughly equipping him for work. Location, New England. 0212-E.

SALES ENGINEERS. Air-compressor manufacturer has several openings for locations in various district offices. State qualifications, experience if any, and compensation expected. Location, Illinois. 0216-E.

SEVERAL MEN WITH MECHANICAL ENGINEERING TRAINING wanted in connection with the various operating and test problems in operation of large power plant.

(a) TWO JUNIOR ENGINEERS with experience in test work on various types of power apparatus. Start with salary of $100 per month.

(b) For the shift operating jobs three vacancies. Start with a salary of $150 per month. Numerous opportunities for promotion and men who make good always considered for transfers to other various plants. Location, Virginia. 0217-E.

PLANNING-DEPARTMENT AND TIME-STUDY MEN. Well-established firm can offer exceptional opportunities for effective and interesting work to engineering graduates with substantial experience in modern industrial methods, with special reference to time study, the determination of standard tasks, planning and scheduling production. In reply state age, education, experience, present and expected salary. Headquarters Boston. 0218-E.

POWER-PLANT ENGINEERS. Well-known industrial concern engaged on important work for the Government wishes to engage the services of several power-plant engineers for the construction and operation of large power plants used in connection with important munition production for the Government. A technically trained college graduate preferred, although equivalent training elsewhere will be considered. Executive experience in the operation of large power plants is essential, supplemented preferably by experience in the construction of large power plants and familiarity with design. Practical experience should cover all of the usual forms of central station equipment and also power distributing systems, refrigeration, compressed air, hydraulic machinery, water-pump machinery, etc. Executive ability is most essential, to be combined with the necessary tact to give successful coöperation. Give fully particulars concerning qualifications including age. Please type information on a full-size letter sheet. 0219-E.

COMBUSTION ENGINEERS, with wide experience in the theoretical and practical operation of boilers and stokers; also executive experience in the operation of very large boiler rooms. Location, Delaware. 0220-E.

DRAFTSMAN AND ENGINEER, one well posted on mechanics and mathematics; up-to-date, with boiler-designing experience. State past experience, advising the past and present employers and how long employed by them, education, nationality and salary expected. Location, Chicago, Illinois. 0221-E.

DRAFTSMEN familiar with power station, piping, and piping layouts for a plant for the U. S. Government. Give age, training, experience, and lowest salary that will be accepted when writing. 0222-E.

SALES MANAGER who will keep in touch with production and shop operations and having wide experience in modern power piping. Eastern Location. 0231-E.

SHOP SUPERINTENDENT for small plant manufacturing gas engines and oil well supplies. Location, Okla. 0233-E.

PRODUCTION MANAGER to systematizing shop; small plant manufacturing gas engines and oil-well supplies. Location, Okla. 0234-E.

HIGH GRADE EXECUTIVE for position as assistant superintendent in factory employing 250 hands, manufacturing duplicate parts. Experienced in handling both men and women employees. Thorough mechanic, experienced in getting work through the shop, operating on a premium basis. State fully in first letter experience, age, nationality, references, salary expected and when available. Location, Ohio. 0235-E.

DRAFTSMAN OR TECHNICAL GRADUATE, mechanical engineer, with one to three years' experience in general mechanical drafting, in an industrial plant. Advise salary expected. Fine opportunity for energetic and original young man. Location, Minnesota. 0236-E.

TECHNICAL MAN experienced in economy and operation of boiler and power-house machinery. Location, East. 0237-E.

TESTING ENGINEER to take charge of testing in steam-turbine manufacturing plant in Western New York. Technical graduate and one with some knowledge of electricity; experienced in handling men. 0238-E.

SUPERINTENDENT, initial qualifications, several years' standing as a technical school graduate, from civil or mechanical engineering course; with energy, good judgment and ability to handle men. 0239-E.

ENGINEER, preferably with field-construction experience or with knowledge of erection work. Salary to start $1800 and good opportunity for advancement. Location, New York. 0240-E.

MECHANICAL ENGINEER AND EXECUTIVE MANAGER for chemical plant. State age, previous employment, salary and when available. Location, New Jersey. 0241-E.

POWER ENGINEER, mechanical and electrical engineer, capable of superintending complete power-plant proposition of cement-manufacturing plant, and of acting as assistant to superintendent of the plant in special study of improvements, fuel conditions, etc. Man 35 to 45. Location, Pennsylvania. 0242-E.

EXPERIENCED ENGINEERING CHECKER. State kind of experience, education, age, nationality and salary. Location, New York. 0243-E.

TOOL AND INSTRUMENT MAKER. Good organizer. Age 35 to 40 years, American born, good personality. Salary, $250. Location, Brooklyn. 0244-E.

EXPERIENCED TOOL DESIGNERS, salary depends on the man. Location, New York. 0246-E.

FIRE PROTECTION ENGINEER. Large plant in Detroit requires man to guard against fire hazards. Should be fully informed as to modern fire-prevention methods, with sufficient training and education in electricity and chemistry to fully appreciate hazards of this sort. In applying, state age, draft status, nationality, extent of education, detailed experience, present employment.

TEACHING POSITIONS. Assistants in mechanical construction and electrical engineering. Location, Rhode Island. 0249-E.

DRAFTSMEN AND CHECKERS. Government work. Location, New York City. 0250-E.

MECHANICAL SUPERINTENDENT for textile manufacturing plant. Salary, $1,800. Location, Rhode Island. 0252-E

SHOP INSPECTOR, preferably 25 to 35 years of age, familiar with car construction or structural work. Salary about $150. Permanent position for the right man. Location, New Jersey. 0256-E.

MECHANICAL ENGINEER. Excellent opportunity for a technical man with shop and drafting room experience with a growing concern in Connecticut making high grade specialized product. Work would be interesting and carries with it considerable responsibility. Applicant must give full particulars in answering. 0257-E

ASSISTANT TESTING ENGINEER, technical graduate, not subject to draft, with experience in steel heat-treatment and testing work, wanted by a growing concern in Connecticut, making a high-grade specialized product; knowledge of chemistry would be an advantage. Good opportunity and work interesting. Applicant must give full particulars in answering. 0258-E.

CONTROLLING INTEREST in prosperous machine tool and gage-manufacturing concern to be sold for best offer. Present owner to enter service. Well-known firm of wide reputation. Location, Connecticut. 0259-E.

CAPABLE PRACTICAL MAN to take entire business control of machine shop building special machinery, gages and tools. Engineer with business knowledge and experience in this line of work preferred. An interest in the business may be acquired by the right man. Location, Connecticut. 0260-E.

SALESMAN familiar with the sale, design and making of special machinery, tools, gages and fixtures, practical mechanical experience necessary. Good opening for right man. Location, Connecticut. 0261-E.

SALES ENGINEER, (0263-E), technical graduate familiar with automobile starting, lighting and ignition apparatus and electrical devices in general. Experience in plastic molding or die casting would be advantageous.

SERVICE ENGINEER, (0264-E), need not be a technical graduate but should be familiar with die casting and hydraulic press work.

If applicants for the above two positions are between the ages of 21 and 31 they should show cause for exemption or have numbers near the end of the draft call. Prefer a single man since the positions will require considerable traveling over a wide territory. Product is highly specialized and the first two or three months of employment will be spent in the shop and laboratory. Salary commensurate with experience and ability. 0263-E and 0264-E.

COLLEGE GRADUATES, men out at least a year, for general shop-engineering work, leading to industrial-management positions, with growing concern. State full particulars. Location, New Jersey. 0265-E.

SHOP SUPERINTENDENT for company manufacturing high-speed machinery for addressing, folding, wrapping and sealing newspapers for the mail. Man over draft age, must be resourceful; technical education, general rather than too highly specialized experience, with all-round shop experience, in machine tool operation, tooling for production, purchasing, laying out of shop, handling men, shop accounting, rate setting, cost production, estimating. Salary will depend on the individual man, his education, experience and native ability. Location, Chicago. 0266-E.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL ENGINEER, Member, at present professor of mechanical engineering in southern university, desires work for summer. Available from June 10 to September 10. Has had shop and drafting room experience, familiar with design of steam pumps, locomotives, and heating and ventilating plants, also building construction. E-118.

MECHANICAL ENGINEER, American, 14 years' practical experience in the manufacture of engineering specialties, machine tools and shop equipment; also power, machinery and shop maintenance, oxy-acetylene, welding, drafting, physical and experimental department. Familiar with brasses, iron and steel. An executive with initiative and aggressiveness. At present employed. Will go any place. Salary, $2800 and expenses. E-119.

ASSOCIATE-MEMBER, can furnish the best of references. Consider permanent position with a strong company. Salary, $2500 to start. Age 32, married. E-120.

MECHANICAL ADVISER AND DEVELOPMENT ENGINEER. Special-machine designer, policy investigator, practical and technical education, good organizer and systematizer. Specialist on mechanical efficiency operation. Expert on substituting mechanical devices for hand labor. Past 15 years specializing on designing, developing and manufacturing up-to-date cost cutting appliances, special equipment, tools and labor-saving devices for manufacturing special product efficiently. Age 35. Assoc. Mem. Salary, $4800. Desire new connections with large corporation contemplating improving or redesigning its present manufacturing methods where above experience is essential. Location, vicinity Newark or New York City. E-121.

GRADUATE ENGINEER, with ten years' active and consistent experience in the practice of principles of industrial management, is not an efficiency engineer or cost clerk. Will associate himself with a bank as industrial expert or with a large manufacturing enterprise as confidential assistant to president or manager, or will take charge of an executive department but not below works manager. Available July 1. E-122.

MECHANICAL ENGINEER desires position with concern in Philadelphia or California. Technical knowledge, drafting and shop experience. Age 36. Married. Full particulars on application. E-123.

PLANT MANAGER. Executive of proven ability, having wide experience in large factory management. Broad-minded with all-round mechanical training and practical knowledge of production methods. Investigate. Your time will not be wasted. Salary expected, $7500. E-124.

MECHANICAL ENGINEER AND EXECUTIVE. Technical graduate, 39 years of age. Six years' experience in design, construction and operation of ore concentrating plants. Six years' experience in sale and manufacture of ore-concentrating machinery, including thorough study of shop production and management. Employed, but desires responsible position with large mining corporation or with company handling government work and needing men of above qualifications. E-125.

MECHANICAL ENGINEER, CHILE, S. A. Technical graduate, M. E., 1911, married, age 30, American, with 7 years' experience in design along hydroelectric and mechanical lines. At present chief draftsman on construction work for large American mining concern. Available September 1. E-126.

EXECUTIVE, MANUFACTURING AND MECHANICAL. Desires to locate in Connecticut. Has wide experience in the manufacture of interchangeable parts for munitions and general hardware. E-127.

MECHANICAL ENGINEER. Member, age 40, American, 22 years' experience on automatic machinery, automatic press tools and deep-drawing press work, 12 years' experience in Connecticut brass shops, and ten years with present employers. Can design, supervise, organize or install new work as mentioned above. Present employer best recommendation. E-128.

JUNIOR MEMBER, expert in machine design, and a good all-around draftsman, desires part time work outside of regular position. E-129.

EXECUTIVE AND PURCHASING ENGINEER, Boston graduate, member, age 40, married, American, 20 years' experience covering the construction, operation, and maintenance of the estimation, appraisal and purchase for manufacturing plants. At present employed as assistant chief and purchasing engineer. Location preferred, New York City. E-130.

COMBUSTION ENGINEER. Associate-member, mechanical engineering graduate, age 30, married, in class IV of the draft, with five years' experience in the combustion of a variety of different American fuels, testing, investigating, designing and economy work, familiar with stokers, and different types of hand-fired furnaces both in high- and low-pressure work. Good record. Capable of responsible work. Only permanent positions considered. Minimum salary $2700. E-131.

MECHANICAL AND ELECTRICAL ENGINEER. Member, Cornell graduate. About twenty years' experience in general engineering and at present chief engineer for a company operating four manufacturing plants. Familiar with conveying, elevating, crushing, combustion, heat balances, testing and gas and steam problems. Highly recommended by present employer. Minimum salary $3000 per annum. E-132.

MECHANICAL ENGINEER, member, technical education, age 40. Sixteen years' experience with two large corporations on construction, power plant operation, and maintenance work, desires new connections as mechanical engineer in charge of engineering department, with medium- to large-size industrial plant. E-133.

SALES AGENT, mechanical engineer, technical graduate, thirteen years' experience in selling, designing, and estimating, desires to represent high-class manufacturer in New England territory with headquarters in Boston. Best of references. E-134.

CHIEF ENGINEER OR MASTER MECHANIC, with thorough technical and practical experience, covering construction, operation, and upkeep of steel plant. Specialty, metallurgical work, heating and melting furnace. E-135.

SAFETY ENGINEER, with six years' thorough technical and practical experience in this capacity, with large steel works in Pennsylvania. E-136.

PRODUCTION MANAGER, experienced on aeronautical engines and parts and high production on light-weight machinery, desires position as executive on Government work. Expert tool designer; experienced in shop efficiency and cost recording; understands all classes of automatic-machine work, including sheet-metal stampings. Salary about $300 a month. E-137.

MECHANICAL ENGINEER, Member, technical graduate, age 39, desires position as engineer or chief draftsman. Expert in design of high-power hydraulic turbines, governors, etc., also shop practice, layout of power plants and design of general machinery. One year's experience in a testing laboratory for machinery and material. E-138.

WORKS MANAGER OR GENERAL SUPERINTENDENT. Member. American, age 50, married. Thirteen years as superintendent and works manager of company manufacturing superheaters and other power plant specialties. A thorough understanding of gray-iron foundry, forge, and machine-shop practice. Has originated and developed machines and tools and proved good organizer and executive; previous experience as erecting engineer of hydraulic machinery. Desires position with growing concern. References. E-139.

ENGINEER, experienced in estimating, correspondence and sales, and in responsible charge of important work, for general machinery, pneumatic, pumping and pipe work. Age 33 years. Associate Member. E-140.

ASSISTANT PROFESSOR in mechanical engineering qualified by experience as a teacher and as an engineer. Well recommended. E-141.

WORKS ENGINEER, with twenty years' experience on engineering and scientific production; thoroughly versed in drafting, inspection, routing, rate setting, maintenance, tools and special machinery; age 40. E-142.

EXECUTIVE, Member, age 42. Present position 13 years. Manufacturing, drafting, construction, estimating and sales experience. Minimum salary $5000. Location New York. E-143.

MECHANICAL-ELECTRICAL ENGINEER, technical graduate with fifteen years' experience. Thoroughly familiar with engineering construction and operation of power stations and sub-stations. At present assistant superintendent with large public service corporation. Desires position as superintendent or mechanical engineer with direct responsibility and opportunity to expand. E-144.

EXECUTIVE OFFICER of leading industrial corporation, American born citizen, 48, graduate mechanical engineer, 25 years' manufacturing and business experience in this country and in Europe, as works manager, sales manager (domestic and foreign) and subsequently as general manager and managing director of European subsidiary company employing 3000 men, with headquarters in Paris. Recently returned to this country, on account of war conditions, and at present is employed as manager of corporation's foreign business. Desires position of responsibility in executive or selling capacity, offering opportunity to produce results. Highest New York and Pittsburgh references. E-145.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

Boston Society of Civil Engineers

At the last annual meeting of the society Prof. George C. Whipple, of the Civil Engineering Department of Harvard University and the Massachusetts Institute of Technology, delivered a presidential address entitled The Engineer as a Social Force in the New Democracy.

In recent years our forecasting of the future has been on a mathematical basis largely, but the problem has now changed to a social one. The new problem is political and ethical rather than physical and mathematical, and the engineer must join the other professions in the effort to solve this problem.

As regards the effects of the war, Professor Whipple expressed his belief that a readjustment of political and social conditions throughout the world is inevitable and that peace and tranquility will not come until these great questions are settled. After the war the great problems of the day will be social problems, and the engineer must play his part in them.

One social problem, as a result of the war, will be that of rewards. Labor is going to demand its share, and the engineer, who acts as intermediary between labor and capital, will be needed to solve the problem. Another great opportunity is offered the engineer for being a social force in the world, namely, to bring about harmony between the work and the worker. Just as the engineer is now the inspector of the work performed, he should also be the inspector of the men who perform the work.

The speaker called attention to the present opportunities for engineering work in foreign fields and declared that the engineer must henceforth think in terms of the world.

San Francisco Association of Members of the American Society of Civil Engineers

At a recent meeting of the association the subject of discussion was, "Why Have Not Engineers Achieved Higher Rank Among the Professions?" Seven members had been asked to prepare short talks on the subject and a committee was appointed to study and bring in recommendations on the various suggestions. The *Engineering News-Record* for March 28, 1918, reproduces some parts of the report of this committee.

There was a consensus that engineers should broaden their general knowledge of affairs; that in addition to a mastery of the technical side of engineering they should cultivate the ability to speak and write well, and after graduation endeavor to broaden by contact with other men, by taking part in civic affairs and by striving to develop administrative and executive ability.

Both the public and the engineer would benefit, it was held, if engineers were more active in public affairs and had a higher professional standing in the eyes of the public and the other professions. If a change in the status of the engineer is to be brought about, engineers themselves must take the initiative. The question then becomes, "What action is desirable?"

The first step, the committee believed, is to establish clearly just what kinds of engineers are being considered and what distinguishes one class from another. The term "engineer" or even "civil engineer" is too broad to constitute a classification. As a starting point, therefore, the committee suggested three classes: (1) Those who plan or design, (2) those who assemble or erect, and (3) those who manufacture or sell.

In other professions, it was pointed out, there are sharp lines of demarcation; the architect is not easily confused with the builder or with the manufacturer of building materials; the profession of the physician is distinct, and excludes the druggist and the chemical manufacturer. But civil engineers have not taken pains to establish such distinctions. Commercial activity has become so closely identified with professional activity in civil engineering that even those involved have difficulty in drawing the line. The layman is naturally less able to do so and therefore a "civil engineer" is generally thought of as a man with more or less specialized training, engaged in a technical phase of commercial activity.

The committee pointed out the need for further study along this line so that there could be an agreement on definition and classification. Objectives particularly desirable, it was believed, are (1) an up-to-date definition of what constitutes a civil engineer; (2) an up-to-date definition of a consulting engineer; (3) the classification of civil engineers professionally into the three groups suggested, and (4) a statement of ethics or standards by which these classifications shall be established.

Aeronautical Society of America

An open meeting was held in the auditorium of the Engineering Societies Building, April 4, at which the first report of the investigating committee of the society was presented.

After an investigation of several months the committee found a good many features in the execution of the American aircraft program to which objections were made—such as exaggerated statements of what has been accomplished; and excessively rigorous censorship, which, in the view of the committee, has interfered with production and precluded effective coöperation with the Government on behalf of the American engineering profession.

As regards the Liberty motor, it was stated that there is no doubt as to its being a good design, but that the production of the motor has been unnecessarily delayed by constant changes. From all information available it appears that while the low-compression low-altitude type may be considered as being developed to such an extent that with proper effort it can be turned over to standardized production in a comparatively short time, the development of the high-altitude type is still in its infancy.

Considerable space is devoted to the discussion of the state of research and invention in connection with the development of the aviation program. It is stated that the actual situation is as follows:

The entire matter is partly in the hands of the Signal Corps and partly of the National Advisory Committee for Aeronautics. The Signal Corps has somewhat over $2,000,000 avail-

able for this purpose and is doing work of a very high grade at the McCook Field, Dayton, Ohio, but the facilities available and the number of men employed are entirely inadequate for the tremendous program of the country.

Likewise, a good deal of research is being done at the Bureau of Standards, chiefly in connection with development of the Liberty motor. Here, again, the work is of the highest grade, but the staff is small and the facilities limited to such an extent that only matters of the most vital importance can be carried out.

The National Advisory Committee was organized long before the United States entered into the war, and consists of a few men who have many other and onerous duties to perform. The committee has at its command no laboratory facilities for testing out inventions and no organized technical staff for their consideration. The appropriation asked by the committee for the next year is only $260,000, an amount entirely inadequate for properly handling inventions affecting the program which may easily run into several billions of dollars.

The investigating committee suggested that the National Advisory Committee for Aeronautics be reorganized into a modern and adequate body with ample laboratory facilities and a staff of men who would devote their entire time to the consideration of new inventions. An adequate appropriation of something like $25,000,000 should be granted to the committee.

Representative John Q. Tilson, of Connecticut, in discussing the report, stated that he, as well as the Aeronautical Society of America, had only an attitude of extreme friendliness to the Aircraft Administration. He ascribed at least some of the delays in the execution of the program to two causes: First and foremost, the fact that the production, which is a purely industrial problem, was placed in the hands of the Army, which means men who, however highly fitted for the performance of their direct duties, were not equipped with the knowledge and experience necessary to handle the great and noble problems involved in putting through the construction of machines running into something like a billion dollars. Men have been called from the outside, from the industries, but they were put into uniforms, and in this way made subject to orders from men who, while superior to them in military rank, knew far less of the direct industrial problems involved. Machine construction ought to be in hands of captains of Industry, and not majors and captains of the Army.

The other cause of delay, of considerably lesser importance, was the constant desire to improve things and the delays due to tinkering with designs, which, in many cases, have already proved their worth abroad. Representative Tilson expressed his conviction that the aircraft program in particular, and the munitions program generally, are practically at the end of their past errors and that new and startling results on a really big scale may be expected.

A more complete abstract of the report of the investigating committee will be found in the *Iron Trade Review*, April 11, 1918. A practically complete report of the addresses at the meeting was published in the *Air Service Journal*, April 11, 1918.

German Textile Use of Nettles

Stinging nettle fiber as raw material for the textile industry is in use in a varying degree in Germany, Austria, Denmark and Switzerland as a result of the shortage of cotton caused by the war.

The British Board of Trade, which has been watching the progress in the use of the nettle, has issued a report, calling attention to the danger of ignoring a substitute which may become a serious competitor with staple industries before the full extent of the risk has been appreciated. Believing this to be the case with the stinging nettle, and hoping to make Germany independent of supplies of foreign cotton, the Germans have studied, tested and adopted it as a war necessity.

Large quantities were collected in the summer of 1916 under the provision *Nessel faser Verwertungsgesellschaft,* the new German war company, holding an exclusive right to purchase, if necessary by compulsion, all stems of stinging nettles (*Urtica Diocia*), whether native or imported. This company claimed that a tissue was obtained from the fiber comparing favorably with that manufactured from American cotton. When mixed with wool, a cloth of soft texture, resembling expensive woolen material, but much cheaper and easily dyed, is said to be produced, although this claim is not confirmed. By adding flax, cloth of other characteristics is obtained.

In Denmark, a government committee experimented with nettles, paying for them at the rate of 7 kroner per 100 kilograms. For textiles, only the fibrous part of the plants is necessary, and the committee favored the putrefaction method of separating this from the rest of the nettle. The main points of this method are:

1 The nettles are harvested in September and October, and are stacked like straw through the winter
2 Tops and leaves are removed
3 Stalks are rotted either (*a*) in a "rotting dam," consisting of a wooden cage sunk in a lake or other natural water, or (*b*) in hot water. The former process takes fourteen and the latter four days with the water at a temperature of 30 deg. cent. Experiments are still continuing to define the correct heat and time
4 Stalks are dried in the open air
5 Stalks cracked in a breaker
6 Stalks teased on a teasing board with a wooden knife
7 Fiber combed through a large iron comb or hackle, which finally removes all the remaining wood.

The fiber is then ready for the ropewalk or the spinning.

One of the difficulties of the putrefaction process is the presence of bacteria. Two prevalent sorts have been discovered, a beneficial and a harmful. It is said the harmful species can be removed by steeping the nettles in running water for two or five hours before commencing to treat them. Experiments are being conducted in the pure cultivation of these bacteria with a view to finding a simpler method of putrefaction. (*Journal of Commerce*, March 22, 1918, pp. 2 and 13.)

Course to Train Drafted Men for Technical Employments

A war-emergency course to train conscripted men for machine-shop occupations, blacksmithing, sheet-metal working, and pipe fitting, has been prepared by the Federal Board for Vocational Education and will be distributed to the schools throughout the country as soon as it can be printed. It is known as Bulletin No. 8.

"There is a critical and constantly growing need for many thousands of mechanics and technicians for Army occupations carried on in and behind the lines of the United States Army," declares the Board of Vocational Education. "Many of these workers, already experienced in similar occupations of civil life, will be secured through the draft and possibly through voluntary enlistment. It is recognized by those in a position to know that the quotas thus obtained will not be sufficient, and that it will be necessary to give special train-

ing to many thousands of men for various occupations and in various ways. The War Department has taken definite steps to provide for this training systematically through Army schools and in some instances at cantonments, but largely at the industrial trade, and engineering schools of the country."

The Federal Board for Vocational Education is acting for the War Department in preparing these courses of study and in dealing with the State authorities in charge of the school work. Men who take these courses, it is declared, "should not be led to believe that they are learning a trade. They are serving their country by learning to do a special job well, though to some e tent this training may be beneficial to them in after life." (*Official Bulletin*, March 29, 1918, p. 7)

International Air Traffic Company

According to the *Neue Freie Presse,* January 4, a new company has been formed in Austria-Hungary styled the International Air Traffic Company (Internationale Luftverkehr-Aktiengesellschaft, abbreviated "Ilag"). It is intended that the "Ilag" shall at first undertake the conveyance of letters and parcels on the route Hamburg-Berlin-Dresden-Vienna-Budapest-Belgrade-Sofia-Constantinople. From points in this main line numerous branch lines will run to the most important cities and traffic centers of Germany and Austria-Hungary, so that, according to present intentions, the whole of Central Europe will be covered, at no very distant date, with a close network of air lines. Passengers will be carried as well as postal matter.

Steps are to be taken to form separate companies in Austria and Hungary. The promoters are in touch with interests in Germany, so that there, too, a company will shortly be formed in close connection with the Austrian and Hungarian enterprises. The Austrian and Hungarian post-office administration, even before the war, had begun negotiations for a contract for postal dispatch, which can only be definitely concluded when the "Ilag" is ready to commence its service; negotiations, however, with municipal authorities have already commenced there with a view to providing landing places suitably equipped in all the towns covered by the new air service.

Meanwhile the legal committee of the Hungarian Aero Association has made an agreement with the Austrian Aero Club and the Imperial German Aero Club of Berlin that the contemplated interassociation conference for the purpose of establishing uniform laws for the air, to which those in Bulgaria, Turkey and Poland interested in the matter, are to be invited, shall take place in Budapest in the second half of 1918. (*Christian Science Monitor,* March 20, 1918, p. 9.)

The New U. S. Enfield Rifle

The Chief of Ordnance authorizes the following:

American troops are armed with a faster-firing and more accurate rifle than used by the Germans, according to our expert designers, manufacturers and marksmen.

The superiority claimed for the American weapon is supported on three counts: 1, quicker firing as a result of bolt-handle design; 2, easier and quicker sighting as a result of sight design; 3, greater accuracy of bullet flight as a result of bullet design, and greater mechanical accuracy of chamber and bore. Each of these points is e plained hereafter.

In both the attack and the defense of trench position the rifles are fired without removing them from the shoulder at a rate called "rapid fire," which is the most rapid rate of magazine fire consistent with quick accuracy.

When the Mauser rifle, with which the German troops are now armed, was designed in 1898, no one could foresee the development of "rapid fire" from the shoulder which followed, and the necessity for which is emphasized by present-day trench warfare.

In all modern rifles a "bolt handle" is used to lock the carriage in the chamber for firing. After each shot the right hand must leave the trigger, grasp the bolt handle, eject the empty shell, thrust home another cartridge—all done by movements of the bolt handle—and then push the bolt handle into the position which again locks the cartridge chamber. Thus the position of this bolt handle in reference to the trigger is of great importance to rapidity of fire.

The Mauser rifle has the bolt handle projecting horizontally from the rifle so that, in locking the bolt for firing, the index or trigger finger is left several inches above the trigger.

In the United States rifle (model of 1917, popularly called the modified Enfield) the bolt handle is bent not only down, but also an inch to the rear so that upon locking the bolt for firing the index finger is guided naturally into position for firing. This feature was adopted from the British Enfield rifle, model of 1914, as made in America for Great Britain. The speed of firing thus gained is considerable. (*Official Bulletin,* March 21, 1918, p. 13)

Proposed Screw-Thread Commission

A bill is now before the House of Representatives, introduced by Representative John Q. Tilson, of Connecticut, to establish a national standard of screw threads. In the record of the House was placed, among other arguments, a strong plea for the enactment of the bill forwarded by Calvin W. Rice, Secretary of The American Society of Mechanical Engineers. The early passage of this legislation was urged by all the witnesses, several of them declaring that the entire munition production program of the United States had been seriously delayed through lack of standardization, and especially because of the failure of various Government departments and manufacturers to reach an understanding as to screw-thread tolerances.

The bill, as reported, provides that the commission shall be composed of the Director of the Bureau of Standards, who shall act as chairman, one commissioned officer of the Army and one of the Navy, the remaining two members to be appointed by the Secretary of Commerce, one of whom shall be chosen from nominations made by The American Society of Mechanical Engineers, and the other from nominations made by the Society of Automotive Engineers. It may be the duty of the commission to ascertain and establish standards for screw threads, which shall be submitted to the Secretaries of War, the Navy and Commerce for their acceptance and approval. Such standards as are thus accepted and approved "shall be adopted and used in the several manufacturing plants under control of the War and Navy Departments, and, so far as practicable, in all specifications for screw threads in proposals for manufactured articles, parts and materials to be used under the direction of these departments." The Secretary of Commerce is directed to promulgate all such standards for use by the public and cause the same to be distributed as a public document. The members of the commission are to serve without compensation. The bill imposes no penalty for failure to conform to the standard established, and it is believed that no other consideration is necessary to induce manufacturers to accept the standards that have been adopted by the Government and will be enforced as to Government contracts. (*The Iron Age,* April 4, 1918, pp. 870-871.)

This Month's Abstracts

[illegible]o papers abstracted in this issue deserve especial men[illegible]. First is a paper by Harold Jeffreys in the *Philosophical Magazine* presenting a mathematical treatment of the problem of evaporation. The writer treats it as one of gaseous diffusion and derives an equation for evaporation identical in form with those that determine the transference of heat and momentum. In fact, an equation is derived where, for the case of transference being due to turbulence only, the coefficient k has the same value in evaporation as it has in transference of heat and momentum. This gives a definite physical meaning to the phenomenon of evaporation that may prove to be of great interest for the inverse question of condensation of vapors and drying of air.

Another paper of great interest is one by Albert E. Guy in the *Journal of the American Society of Naval Engineers*. In discussing the lateral flow of water under low heads the writer, among other things, shows that the so-called varying flow-head theory is untenable and also that the usual assumption that the pressure within the jet in the case of flow through a thin-plate orifice is atmospheric, is erroneous, and the common practice in measuring the flow through a horizontal orifice by means of the pitot tube with the pointed end of the tube placed along the horizontal diameter is wrong with such heavy fluids as water, since it results in showing a velocity and consequently a volume greater than the actual. A rather novel theory is offered to explain the generation of the velocity of flow of water issuing from a container through a lateral orifice into the atmosphere.

Fundamental systems for steam turbine alternators are discussed from a practical point of view. Among other things is given a formula for the loss on static head equivalent to the resistance to the passage of air through a round or square sheet-metal air duct.

The use of spruce in aeroplane construction is considered on the basis of tests made by the Forest Products Laboratory of the Forest Service, including the relation of shrinkage to specific gravity. In this connection the tests have proved that spruce tends to show a greater shrinkage in heavier pieces than in light pieces, and as a result of this pieces of low weight are likely to cause less trouble from shrinkage than the heavier and stronger pieces.

Substitutes in the German electrical industry are briefly discussed in an abstract from a British publication.

In the section Evaporation two tests are reported from the *Journal of the American Society of Naval Engineers*, one of a Reilly multicoil evaporator and the other of a "jetflo" regenerative evaporator. The tests on the latter are reported in some detail.

Jean Rey, in the *Proceedings of the French Academy of Sciences*, presents a paper on the entropy diagram of gasoline. The interesting part of this paper, which will be more fully abstracted in an early issue, lies in the fact that the thermal properties of gasoline appear to be directly opposite to those of water. For example, the saturated vapor of ordinary gasoline is superheated through fall of pressure.

The engines of the German "Gotha" biplane are described with their half-compression gear. The water pump and the air pump are also described and illustrated.

Annealing by muffle and pot ovens is discussed in a paper by Joseph B. Deisher. Among other things the writer emphasizes the great importance of maintaining a proper rate of cooling, particularly where it is desired to complete the annealing process in the shortest time possible.

A new pressure table for Elev lead crushers is discussed on the basis of the discovery made by H. W. R. Mason: namely, that lead crushers have the capacity of self-annealing, which is a function of the degree of decrement (or degree of resistance developed) and of time. This discovery, which is of immediate interest of course to manufacturers of munitions, may also prove of a much wider interest in view of the fact that the whole subject of the physical properties of lead is likely to undergo a profound reconsideration in the near future. Thus, it has already been stated that the accepted value of the atomic weight of lead may have to be changed and that possibly lead may have more than one atomic weight.

The influence of winter temperatures on locomotive capacity is discussed by W. L. Bean, Mem.Am.Soc.M.E., who states that a drop in temperature decreases the capacity of the boiler and also greatly increases the train resistance, because of the increase of journal friction with the increase in the viscosity of the lubricant. In this way cold weather appears to cut down the efficiency of train operation at both ends. The writer gives an interesting table showing the number of engines which would have to be added in a normal December and a normal January to make up for the loss of operating efficiencies due to winter temperature as compared with summer conditions.

In the section Research special attention is called to the description of the aerodynamic laboratory of the Leland Stanford Jr. University by Prof. Wm. F. Durand, Mem.Am.Soc. M.E. Some of the instruments in this laboratory have been developed especially for aerodynamic work, and the laboratory promises to become an important auxiliary for the testing of design factors of aeroplanes. The equipment for testing of air propellers appears to be especially complete.

A description of an installation where an air heater is provided for each boiler is abstracted from a British publication.

From *The Iron Age* is abstracted an article describing and illustrating a novel type of boiler baffles made of a refractory composition shipped in plastic condition and having a coefficient of expansion so small that the shape of the baffle practically does not change through variation of temperature. It is claimed that this permits of securing a highly airtight baffle.

An abstract of an article in *Power* gives particulars of a modified method of handling boiler pumps devised to prolong the average life of economizers. In this case the arrangement is such that all economizers get the water from the primary heater at a low operating pressure, the pump being in two stages as shown in the illustration.

"Torcrete" is a reinforced concrete specially prepared for ship construction and is said to bear about the same relation to ordinary concrete as rolled steel does to cast iron. Instead of being poured in forms the materials are shot in place by means of compressed air with the "tector," a new type of concrete blower. The processes are the invention of a Mr. Weber. The preparation is discharged on layers of steel fabric or wire mesh, and there may be as many layers as is necessary to produce the required thickness, the layers themselves massing with one another so as to form a perfect solid. It is claimed the torcrete vessels are lighter than wooden ships, built in shorter time and at lower cost than any other type of concrete ships, and that the method of construction is adapted to any size of craft or any form of metal that may be desired. A vessel of 3200 tons displacement has been contracted for by the Southern Oil and Transportation Company. (Philadelphia *Public Ledger*, April 6, 1918, p. 17)

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Tools, Munitions, Varia

Aeronautics (See also Internal-Combustion Engines and Engineering Materials)

. The Theoretical Basis of Model Strength Tests for Aeroplane Structures, W. L. Cowley, and H. Levy. *Engineering*, vol. 105, no. 2722, March 1, 1918, pp. 219-221. (to be continued.)

Points in British Air Policy. *Automotive Industries*, vol. 38, no. 14, April 4, 1918, pp. 676-679. Based partly on a debate in the House of Commons on February 21 and also on articles in British medical periodicals. The most interesting part of it is that referring to medical attention to air pilots and influences affecting them in flight.

The Air Force Estimates. *Aeronautics*, vol. 14, no. 223 (New Series) February 27, 1918, pp. 194-199. Same as the preceding abstract, with the difference that the text of the debate is given more completely.

Aeroplane's Parts at a Glance. *Aerial Age Weekly*, vol. 7, no. 1, March 18, 1-18, pp. 52-53, 3 figs.

Air Engineering (See also Steam Engineering)

Ventilation Systems for Steam Turbine Alternators, E. Knowlton and E. H. Freiburghouse. In modern turbo-generators as much as six times (or possibly more) the power is secured from a pound of material as was in the first large units. This means that proportionate quantities of heat must be dissipated per pound of material, and to prevent serious rise in temperature special means of cooling are necessary. For turbo-generators some sort of forced ventilation is usual.

The quantity of air required for cooling the generator depends on several factors in design, but in general varies approximately with the total losses of the machine minus those in the bearings.

The usual arrangement is that the air passing through the generator may be admitted and discharged wholly outside the turbine room or wholly inside, or partly inside and partly outside. This allows considerable control of generator and turbine-room temperatures throughout the year, and during the coldest weather the air that is passed through the generator may be admitted from and discharged inside the station. A suggestion is made to use the heated air discharged from the alternator for combustion under the boilers.

The design of air ducts is carefully analyzed and formulæ given. The difference in pressure expressed in inches of water necessary to pass the air through the duct is expressed as the loss in static head, the duct being assumed to be round or square sheet metal. This loss is then

$$H = [a + b + (c \div 39)]H_v$$

where H_v = the velocity head
a = the number of right-angle turns
b = the number of abrupt reductions in area
c = the length of duct ÷ diameter of duct.

Attention is called to the importance of maintaining the alternator and ducts free of dirt. In view of the fact that little data are available on the difference in operating temperature between a clean and a dirty machine, the following results of two tests on machines in commercial service are of interest. The loads were the same under both conditions:

	Dirty	Clean
Machine 1—Rise of armature winding, deg.	54	[illegible]
Machine 2—Rise of armature core, deg.	54	[illegible]

For cleaning the air an air washer is claimed to be preferable to screens. But if an air washer is used, it is quite important that all free or entrained water be removed from the air before it leaves the washer. The operation with air washers is discussed in detail. (*General Electric Review*, vol. 21, no. 4, April 1918, pp. 240-246, 5 figs., 5 tables.)

Testing an Air Compressor, Walter S. Weeks. Data of tests of an air compressor as carried out at the University of California for the purpose of giving an answer to the following two questions: How much does the compressed air cost? and is the compressor doing all that it should? In the course of this investigation a highly interesting chart of nozzle discharge was developed.

The paper suggests that all makers of air compressors should agree on a standard method of testing, and it is further suggested that a compressor be guaranteed with respect to horsepower input per 100 cu. ft. of air delivered, with the way of measuring the air carefully determined. (*Mining and Scientific Press*, vol. 116, no. 14, April 6, 1918, pp. 479-482, 2 figs.

Engineering Materials

The Use of Spruce in Aeroplane Construction, J. A. Newlin. The paper presents data obtained by the Forest Products Laboratory of the Forest Service. It gives some

[illegible] information relative to the species and conditions of growth of spruce, the influence of moisture conditions on aeroplane stock, and the relation of density to moisture content, shrinkage and strength. As density is recommended as the best criterion of strength qualifications, methods of determining density or specific gravity are included.

Spruce follows the general law of timber in regard to strength properties and weight: namely, all the strength values increase in proportion to the specific gravity. Two curves are given showing the variation of modulus of elasticity and maximum crushing strength with changes in specific gravity. It is found, among other things, that clear wood with specific gravities of 0.33 (based on value when green) or over 0.36 (when based on oven dry value) would seldom run below 4500 lb. per sq. in. in modulus of rupture or below 2000 lb. per sq. in. in maximum crushing strength along the grain when green. Drying to the condition of aeroplane stock would increase these minimum strength figures to about 8000 lb. and 4000 lb. per sq. in., respectively.

The conditions of moving material at the aeroplane factories are such that there must be of necessity a wide variation in the moisture content of machined material, the factors affecting this moisture content being: variations in the original moisture content, position of the specimen in the pile or conditioning chamber, and the difference in density of individual pieces which cause them to dry at different rates. It has been generally observed that of two pieces of the same species but different in density, the lighter piece will dry the more rapidly. The laboratory observations lead to the belief that a variation of as much as 10 per cent in the moisture content of the material as it goes through the machine may be expected, although no data on this point are available.

The relation of shrinkage to specific gravity is given in the form of a chart, the law in this case being expressed as a straight line.

Good spruce may be assumed to shrink about 12.5 per cent from the green to the oven dry condition. Were the material allowed to stand for several weeks at approximately the humidity condition of the assembling room before manufacture, it would probably all arrive at about a uniform and suitable moisture content, but under the forced conditions which exist, it is safe to assume that the better pieces of machined timber frequently have at least 5 per cent more moisture than they will ultimately have. This change of 5 per cent moisture, which may occur between the time of machining the part and its final use, might cause a reduction in one dimension of nearly 2 per cent and in the other of nearly 5 per cent, an amount of change sufficient, for example, in a built-up propeller to split and twist it.

An important part brought out by the tests is that spruce tends to show a great shrinkage in heavier pieces than in light pieces. Consequently, pieces of low weight, which would be considered of low quality, would not cause so much trouble from shrinkage as the heavier and stronger pieces. Hence, by throwing out material on account of a very slight undersize, except where the dimensions are taken immediately after machining, higher-quality pieces are likely to be excluded. (*Aerial Age Weekly*, vol. 7, no. 3, April 1, 1918, pp. 162-163, 3 figs., *ep*)

ACID-RESISTING IRON. Brief abstract of a paper read by Sidney L. Tongay before the London Section of the Society of Chemical Industry on March 4.

The paper discussed in detail the troubles encountered in making acid-resisting iron, due to its great shrinkage and the possibility of some of the compounds separating out during process of cooling and forming eutectics. Some tests recently made at the Manchester School of Technology showed that these eutectics consist largely of phosphorus and silica. These difficulties were largely overcome by suitable furnaces and improved manipulation in mixing the metal.

The paper gives the physical constants of acid-resisting iron as compared with cast iron. The heat-transmitting power of acid-resisting iron has been calculated at ten times that of stoneware or quartz, which makes it possible to make the parts much smaller. (*The Practical Engineer*, vol. 57, no. 1620, March 14, 1918, p. 127.)

A BIBLIOGRAPHY OF ALLOYS, Clarence Estes. *Metallurgical and Chemical Engineering*, vol. 18, no. 6, March 15, 1918, p. 312.

RAPID GROWTH OF AMERICAN MAGNESIUM INDUSTRY. *Metallurgical and Chemical Engineering*, vol. 18, no. 6, March 15, 1918, pp. 284-285. Brief data on the growth of the American magnesium industry now concentrated in the hands of two companies, The American Magnesium Company, at Niagara Falls, and the Rumford Chemical Company, at Rumford, Maine. Some data are given on the production of magnesium-aluminum alloys.

SUBSTITUTES IN THE GERMAN ELECTRICAL INDUSTRY. Discusses the question of substitutes in the German electrical industry and the way it was handled. The greatest difficulty which the electrical industry had to face in Germany was the shortage of copper and its alloys. The Germans developed the use first of zinc in the form of drawn wire and succeeded in reducing to some extent its brittleness and sensitiveness to change of temperature. Further new alloys of magnesium appeared, such as electrone (10 per cent aluminum, 90 per cent magnesium). Older alloys such as magnalium and duralumin were also used as well as iron.

In insulating materials, paper in different forms and compositions have to take the place of former materials. Regenerated rubber, that is, refined rubber substitute, took the place of soft rubber, while for hard rubber is used an artificial product of phenol and formaldehyde called faturan (a product of the same origin is called bakelite in America).

As a substitute for oil in electrical apparatus, a material called benzinoform was proposed, a substance developed from carbon tetrachloride (the material used in America in fire extinguishers). So far the experience with it has not been satisfactory because of its excessive volatility. (*Engineering*, vol. 105, no. 2723, March 8, 1918, pp. 246-249.)

THE CONSTITUTION OF THE COPPER RICH ALUMINUM-COPPER ALLOYS, J. Neill Greenwood. *Engineering*, vol. 105, no. 2724, March 15, 1918, pp. 277-281, 6 figs., 16 tables (to be continued). First part of an investigation conducted in the metallurgical department of the Victoria University at Manchester. An abstract will be given in an early issue.

Evaporation

Some Problems of Evaporation, Harold Jeffreys. A mathematical treatment of the problem of evaporation, which the writer considers as being practically one of gaseous diffusion. With this in view he gives an equation identical in form with those that determine the transference of heat and momentum.

If V denote the fraction of the density of the air at any point that is due to water vapor, V will vary from time to time and place to place according to the equation

$$\frac{dV}{dt} = \frac{\partial}{\partial x}\left(k\,\frac{\partial V}{\partial x}\right) + \frac{\partial}{\partial y}\left(k\,\frac{\partial V}{\partial y}\right) + \frac{\partial}{\partial z}\left(k\,\frac{\partial V}{\partial z}\right) \ldots . [1]$$

where k is the effective coefficient of diffusion, t the time, and d/dt denotes the total differential following a particle of the fluid. In general, V, as above defined, will be referred to as the concentration.

Then if u, v, w be the components of velocity and V be supposed to be expressed as a function of x, y, z, and t,

$$\frac{dV}{dt} = \frac{\partial V}{\partial t} + u\,\frac{\partial V}{\partial x} + v\,\frac{\partial V}{\partial y} + w\,\frac{\partial V}{\partial z} \ldots\ldots\ldots [2]$$

The boundary conditions are that the air in contact with a liquid surface is saturated, so that V is equal to the concentration in saturated air at the temperature of the liquid, and that at the great distance.

When the transference is due entirely to turbulence, the quantity k has the same value in evaporation as it has in the case of transference of heat and momentum.

The rate of transference outwards is given by an equation which determines the rate of evaporation, the latter, other things being equal, being proportional to the linear dimensions, since the electrostatic capacity varies in this way on bodies of the same shape. In this way the present formula agrees with Stefan's solution, which has been experimentally proved to be correct subject to certain conditions.

The case of evaporation due to steady wind blowing over a flat surface of water is next considered, and an equation is given expressing the amount of evaporation taken over the whole area. In particular, it is shown that for areas of the same shape and dimension proportional to a, the rate of evaporation would be proportional to $a^{1.5}$. This again is in accordance with the experimental results for bodies of medium dimensions discovered by Thomas and Ferguson.

The evaporation from a circular cylinder wet at the bottom and open at the top is considered next, as well as the very biologically important case of evaporation from the surface of a leaf. (*The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science*, vol. 35, no. 207, March 1918, pp. 270-280.)

Test of Reilly Multicoil Evaporator (Submerged Type), H. T. Dyer. A portion of the results of a test on this type of evaporator. It has been found that—

a There is an average reduction in capacity of about 11 per cent for each 1/32 increase of salinity.

b For each number of coils, vapor pressure and temperature difference there is a best water level for maximum capacity and safe operation with low chlorine content and no danger of priming.

c For vapor pressures below the atmosphere, the number of coils must be decreased to insure satisfactory operation.

d In order to obtain a capacity of 5000 lb. per hour for this evaporator, the blowdown must occur at intervals of 20 min. To avoid this too frequent blowdown, either continuous blowdown must be used or the water space of the evaporator must be greatly increased.

e The construction of the coils is such as to provide a very effective means of self-scaling of coils by sudden changes in temperature.

f The vapor produced is of exceptionally low chlorine content when the water level and temperature difference is within safe limits. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 1, February 1918, pp. 78-98, 14 figs.)

Test of Regenerative Evaporating Apparatus, M. C. Stuart, Mem.Am.Soc.M.E. Data of tests recently made at the United States Naval Engineering Experiment Station, Annapolis, upon a patented system for the regenerative operation of evaporators, in which the efficiency of multiple effect evaporation was obtained with a single evaporator shell.

The essential feature of the system consists of a compressor called a "jetflo" compressor, Fig. 1, the function of which is to

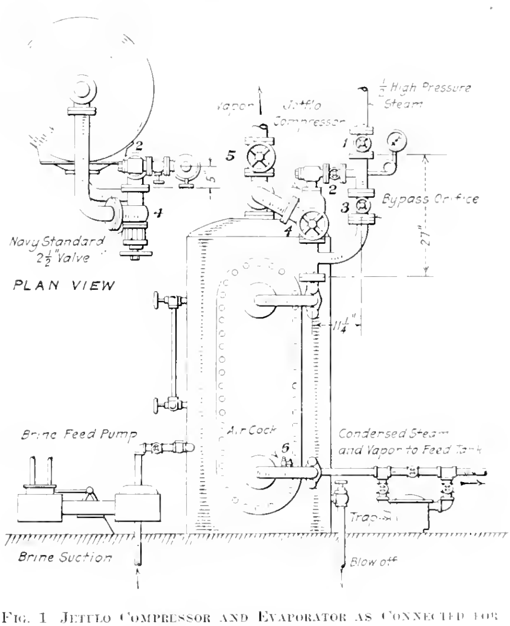

Fig. 1 Jetflo Compressor and Evaporator as Connected for the Tests Described

compress, by the use of live steam, part of the vapor produced by the evaporator and to return to the coils of the evaporator the compressed vapor together with the steam used in compressing it.

The principal objects of the tests were to determine for various conditions of operation the amount of steam used by the compressor, the vapor entrained and compressed, non-entrained vapor produced, total vapor produced, amount of compression produced by the compressor and temperature difference maintained between coils and shell. Besides these data certain facts were established by the tests.

Comparative performances of the jet compressor when equipped with two separate nozzle tips, as well as the typical performance characteristics of the jet compressor, are shown in Fig. 2. In the lower curves the pounds of vapor entrained per pound of steam supplied are plotted against the amount

of compression produced. That there is a definite relation between these two quantities for constant steam and vapor pressures is shown by the fact that for each nozzle tip the test points for all runs fall on a smooth curve which may be

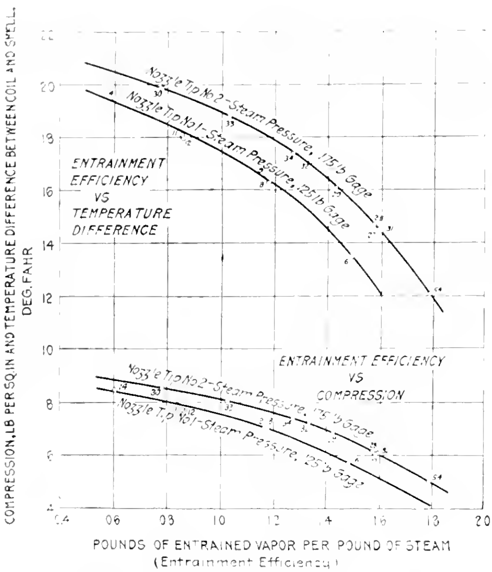

Fig. 2 Comparative Performance of Two Nozzle Tips on Jetflo Compressor

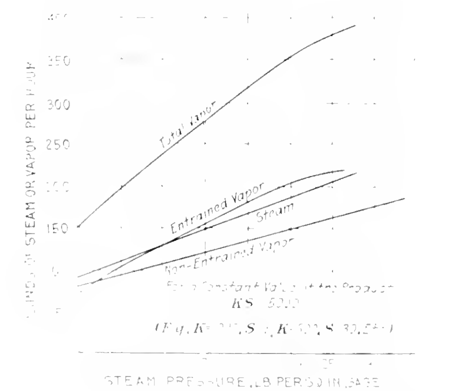

Fig. 3 Curves Showing Effect of Steam Pressure on Capacity of Compressor

termed a characteristic of the compressor. In the upper curves the pounds of vapor entrained per pound of steam are plotted against the temperature differences, and here also the points for each nozzle tip fall on a smooth characteristic curve.

Lines of constant value of the ratio pounds of vapor entrained per pound of steam used, which might be termed the entrainment efficiency, were drawn by the use of the relation: weight of condensate = weight of steam times (1 + entrainment efficiency). Within the range of proper operation of the compressor the entrainment efficiency varied from zero to 1.89 lb. of vapor entrained per pound of steam used.

It developed during the test that the performance of the jet compressor in connection with the evaporators was constant for a constant value of the product of heat-transfer coefficient and surface; that is, if the compressor operated at a certain point in its characteristic with the value of $K = 1000$ and $S = 10$ sq. ft., it would operate at the same point for values of $K = 500$ and $S = 20$ sq. ft.

To show the effect of steam pressure on capacity and efficiency several curves plotted from test data are given in the original article. Thus, the curves in Fig. 3 show that for a value of the product $KS = 15{,}000$, the steam, non-entrained vapor and entrained vapor each increase with increasing steam pressure. From another figure not reproduced here and showing the variation of efficiencies with steam pressure, it is seen that the non-entrained vapor produced per pound of steam is nearly constant at various steam pressures; this is due to the fact that, approximately speaking, the latent heat of the entrained vapor forms a closed cycle within the apparatus, being alternately given to the entrained vapor in the shell, given up therefrom in the cells and reappearing as latent heat of the steam in the non-entrained vapor.

From still another figure it is apparent that both the efficiency and capacity are increased by increasing either the surface or the heat-transfer coefficient in the product KS. For the smaller amounts of surface there is a considerable variation in capacity and efficiency with heat-transfer coefficient, but with the larger amounts of surface installed there may be a considerable variation in the value of the heat-transfer coefficient with little effect upon the capacity and efficiency.

The heat balance of the system is shown diagrammatically in Fig. 4, which gives the distribution of all heat units involved in the production of one pound of vapor. A weight of 1.10 lb. of a mixture of steam and vapor is required in the coils to produce 1 lb. of vapor, in this respect the action being

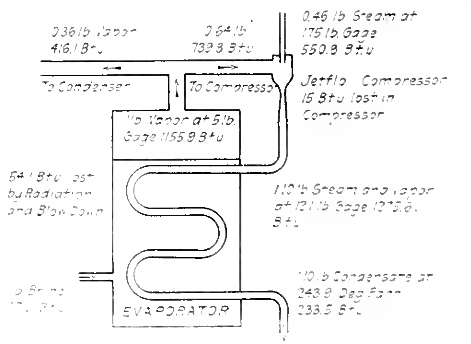

Fig. 4 Heat Balance of the Jetflo Compressor System

similar to the usual single-effect evaporator. The efficiency of the regenerative system lies in the fact that of the 1.10 lb. of mixture required in the coils only 0.46 lb. is required from the steam line and the remainder, 0.64 lb., is obtained from the entrained vapor which is compressed and returned to the coils and condensed in place of going to the distiller condenser to be condensed.

During operation of the evaporator the main steam valve

is opened wide, no throttling being required unless it is desired to operate at reduced capacity. When operating in connection with a distiller condenser in which atmospheric pressure is carried, the vapor valve to the condenser is opened wide. The valve in the vapor line to the compressor is left wide open, and the amount of vapor compressed and the pressure in the coils will adjust themselves. The maintenance of the proper water level, bleeding the air from the coils, attention to the drain from the coils and the maintenance of the proper salinity of the brine must be taken care of as in ordinary evaporator operation.

The system for the regenerative operation of evaporators, whereby part of the vapor is compressed by means of a jet compressor and returned to the coils, produces approximately the efficiency of a triple-effect plant in a single evaporator shell. The system operates with a relatively low temperature difference, and the amount of surface required to produce the desired capacity must be proportioned in accordance with the values tabulated in Fig. 2. An economical point of the design and operation of the system tested is for a steam pressure of 225 lb. gage and 17.48 sq. ft. of surface per 1000 gal. per day, assuming a heat-transfer coefficient of 1000. For these conditions the temperature difference will be 20 deg. fahr., and 2.15 lb. of total vapor is produced per pound of steam used. For lower values of heat-transfer coefficient the surface required must be increased inversely with the value of the heat-transfer coefficient. The use of a larger amount of surface results in increased efficiencies with the same amount of steam used. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 1, February 1918, pp. 41-59, 12 figs., *e*)

Foundry

Die-Casting of Aluminum-Bronze, H. Rix and H. Whitaker. Paper read before the Institute of Metals on March 13, 1918, describing, among other things, the experiences of the authors in the production of die castings, especially 60:40 brass. A program for a scientific investigation into die casting is proposed, with a reservation, however, to the effect that the principal secret of die casting is experience. Om Uppskattning av Gasformiga Brännmaterials Relativa Värde, Alf Grabe. Bihang till *Jern-Kontorets Annaler*, Arg. 19, no. 1, January 15, 1918, pp. 1-11, 2 figs., 2 tables. Description of methods of determining the relative heat value of gaseous fuels.

Diagramme Entropique du Petrole, M. Jean Rey. The physical laws of vaporization of gasoline are here expressed in the form of an entropy diagram, which will be reproduced in an early issue. The two main conclusions arrived at are that (1), the saturated vapor of ordinary gasoline is superheated through fall of pressure, and that (2), the heat of the liquid is always considerably higher than the heat of vaporization, both of these properties being opposite to those of water vapor. (*Comptes Rendus Hebdomadaires des Séances de L'Academie des Sciences*, Tome 166, no. 9, March 4, 1918, pp. 387-390, 1 fig.)

Unpreventable Losses in Coal Combustion Under Boilers, Haylett O'Neill. Calculations showing the relative magnitude of the various unavoidable losses in the combustion of coal under boilers. Charts are given showing (1) the relation between hydrogen, excess of air and carbon dioxide, (2) ratio of moisture to dry air for various humidities, and (3) relation between ash in the coal and heat value. An interesting chart gives the separate and total necessary losses as calculated in the paper. (*Power*, vol. 47, no. 15, April 9, 1918, pp. 502-504, 5 figs.)

Hydraulics

Lateral Flow of Water Under Low Heads, Albert E. Guy. Discussion of flow through a lateral orifice, with special regard to the question of head causing such a flow.

The case under consideration is that of a container filled with water and provided with the lateral orifice near its lower end. If water be allowed to flow freely out of the orifice into the atmosphere, the velocity of flow through the most constricted section of the issuing jet is generated at any given instant by a head having for its height the distance from the center of the orifice to the level of the water in the container at that instant. This velocity is somewhat diminished by friction against the walls of the orifice, with the further reservation that the head measured should represent only an approximate average between those obtaining at the upper and lower strata of the jet. As the head is made smaller, the condition gradually approaches that of the flow in open conduits or in river beds.

The writer discusses the application in this case of Bossut's equation and its possible limitations, as well as its application to an orifice only partly filled vertically by the outflowing water. (Case investigated by Poncelet and Lesbros.)

In that case it was found (Fig. 5) that there was a very noticeable rise of the vein past the lower edge of the orifice, the angle at the edge being 54 deg. According to the theory

as explained by Bossut, the flow head should be the greatest above the edge. If so, the velocity would be maximum there and the underside of the vein would be expected to remain a horizontal plane for quite a distance from the sill. This rise of the lower part of the vein may be observed with any kind of orifice when the depth of water from the sill to the bottom of the container is larger than the vertical thickness of the vein through the orifice, and the writer believes that the true significance of such rise has not been realized previously.

This, in connection with the fact previously observed, that very definite stream lines exist throughout the mass of water in motion in the container and converge from all sides toward

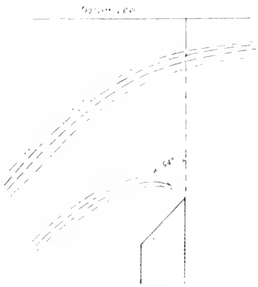

Fig. 5 Poncelet and Lesbros Experiment on the Flow Through a Partially Submerged Orifice

the orifice in the direction from the bottom to the sill, makes the so-called "varying flow-head theory" untenable.

From this the writer passes to the consideration of the general distribution of velocity at different points in the cross-section of a channel, and, referring to Fig. 6 (first shown by Darcy in 1857), he considers as predominant the fact that the velocity is very nearly constant along one even circuit, and in particular that it is practically the same at the lower extremity

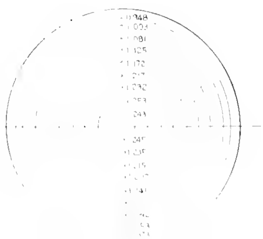

Fig. 6 Darcy Curves of Velocities of Flow Through a Cement Pipe

of a vertical diameter as at the upper end. It seems evident, therefore, first, since at the two ends of a vertical diameter the velocity is the same, that velocity is due to one head only, which in this case corresponds to the slope of the pipe, and second, that were it not for the frictional disturbances the velocity would be uniform throughout the whole section.

The question next discussed is whether there is a difference between a given cross-section of a stream flowing in a circular conduit and of a contracted vein flowing from a thin-plate orifice into the atmosphere, the flow being horizontal in both instances.

The writer shows that the usual assumption that the pressure within a jet is atmospheric is erroneous, and that the common practice in measuring the flow through a horizontal orifice by means of the pitot tube with the point of the tube placed along the horizontal diameter is wrong with such heavy fluids as water, since it results in showing a velocity, and, consequently, a volume, greater than the actual.

The measurement of hydrostatic pressures in the container and the question of various orifices are next discussed in detail. In this connection the writer discusses also the rotation of a jet issuing from an annular orifice, which he ascribes to the fact that the fluid is imperfect, that is, viscous, and is, therefore, subject to friction within itself, and also because the walls of the orifice and of the container are also imperfect and subject to friction. This friction is most intense along the edges of the orifice, and hence the streams in contact with the edge are retarded in their motion. Because of the velocity this retardation is communicated successively to the adjacent streams with diminishing intensity from the edge to the axis of the orifice where the velocity is known to be greatest, the axial portion of the jet flowing more easily and rapidly as the rest requires such active feeding from the upper level that a depression forms, which goes on increasing and assumes a funnel shape finally.

The most interesting part of the discussion is the theory that the velocity of flow of water issuing from a container through a lateral orifice into atmosphere is generated by the head or static height measured from the top of the contracted section of the issuing vein to the upstream level in the container. This assumes, of course, that the pressure upon the upstream level is that of the atmosphere; if it is not, the difference of pressure expressed in terms of head must be added or subtracted from the static height. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 1, February 1918, pp. 60-77, 10 figs., *e*)

Internal-Combustion Engines

The Engines of the German Gotha Biplane. A series of articles is now appearing in *The Engineer* (the first article appeared on February 22, 1918) describing the engines of captured German aircraft. The first articles described the Maybach engine as used in the zeppelins and other airships. The present article describes the Mercedes engine as used in big Gothas.

One of the interesting features of this latter engine is the so-called half-compression gear used in order to reduce the compression when the engine is being started.

For this purpose means are provided (Fig. 7) whereby the camshaft may be moved longitudinally through a short distance so as to bring into action an additional face on each exhaust cam. The small auxiliary cam face is formed on the mid-axis of the exhaust cam towards one side and during the compression stroke opens the exhaust valve 12 deg. above the bottom dead center, and closes to 44 deg. before the top dead center. The edge of the auxiliary cam and of the roller in the rocker arm are beveled to 45 deg. to permit of easy engagement when the camshaft is shifted. The longitudinal movement of the camshaft is effected by partially rotating the handle shown at its end in the illustration. This handle is attached to a gun-metal collar contained within an aluminum housing and threaded internally.

The thread within the collar engages with the thread on the exterior of a steel sleeve, the forward end of which is flanged to engage with the double ball thrust bearing fixed to the end of the camshaft. The beveled gearwheel driving the camshaft

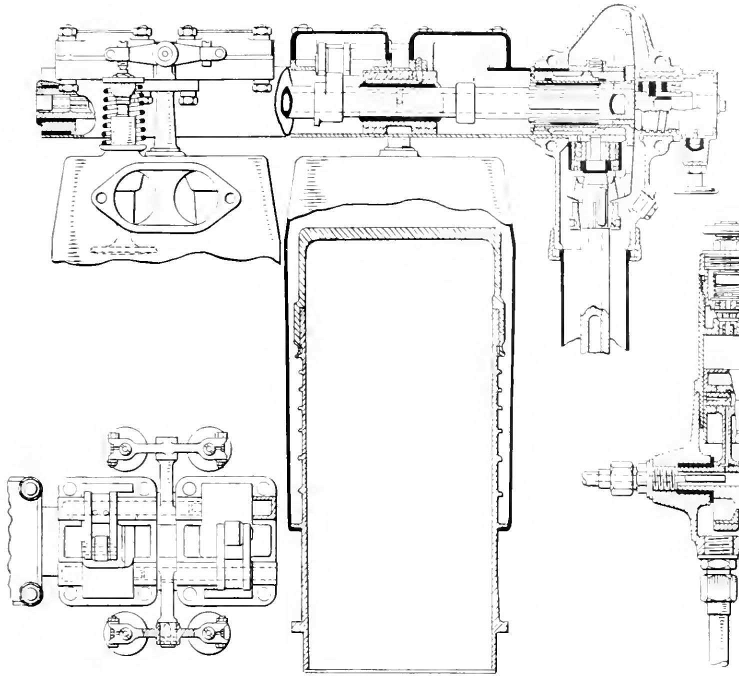

FIG. 7 ARRANGEMENT OF CAMSHAFT AND HALF COMPRESSION GEAR

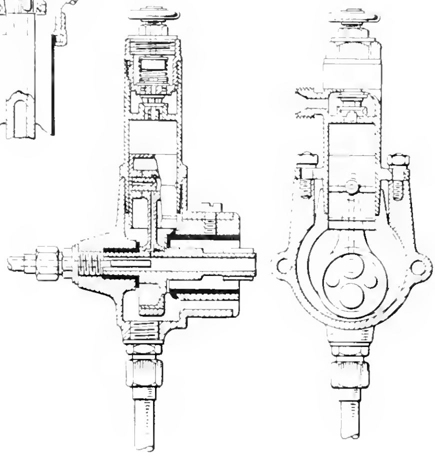

FIG. 8 AIR PUMP

has an extended boss that fits within a split gun-metal bearing driven into the rear end of the camshaft case. The interior of this boss has six serrations which engage with similar serrations on the camshaft so that the movement of the latter does not affect the meshing of the beveled wheel with the beveled pinion.

The drawing reproduced here is taken from an official report but it does not appear to be correctly sectioned.

The cooling water is circulated by means of a centrifugal pump disposed with the axis of its rotor vertical and collinear with the axis of the vertical shaft driving the camshaft—see Fig. 7. It is driven through bevel gearing from the crankshaft. As shown in the section of it given in Fig. 9, the pump draws its supply from below. The vanes formed on top of the rotor serve to throw the water away from the spindle, the object presumably being to assist in the prevention of leakake. The spindle is not provided with a packing gland. Instead of it a hardened steel washer is let into a groove turned in the upper face of the rotor and is pulled up against the lower end of the spindle bush by a spring acting, through a ball thrust bearing, against the under side of the flanged head of the spindle. The flanged head is provided with two claws that engage with the foot of a short vertical driving shaft as illustrated in Fig. 7. The spindle of the pump is lubricated by means of a grease cup operated by a ratchet from the pilot's seat.

The petrol is fed to the carburetor by placing the tanks under air pressure. The air pressure is supplied by a small pump, Fig. 8, mounted at the front end of the camshaft and driven by it through serrations, which preserve the driving connection when the half compression handle is rotated and the camshaft slides. The bore of the pump is 26 mm., camshaft diameter 27 mm. The drawing does not show the inlet port, but the delivery valve is seen on the center line above the piston. The air is delivered into a small chamber from which a connection is taken to the fuel reservoir. In the top wall of this

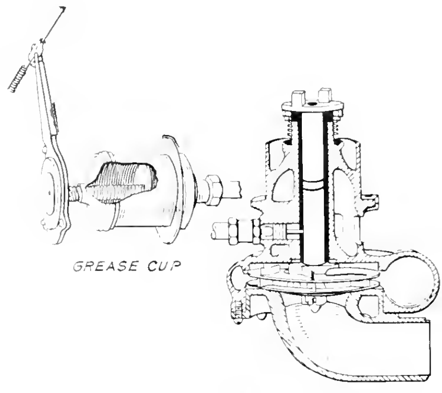

FIG. 9 WATER PUMP

chamber, ports (closed by a flat disk valve) are formed to relieve excess pressure. The strength of the spring behind the disk valve is adjustable by means of a screw handle, the stem of which is hollow and affords a passage for the surplus air.

The oil pressure pump, of a rather complicated design, is described in some detail in the original article. A special oil-supply pulsation damper is also described and illustrated. (*The Engineer*, vol. 125, no. 3244, March 1, 1918, pp. 182-184 illustrated, *d*)

Lubrication (See also Railroad Engineering)

STUDIO SUGLI OLI LUBRIFICANTI PER TRASFORMATORI. *Rivista Tecnica delle Ferrovie Italiane*, Anno 7, vol. 13, no. 2, February 15, 1918, pp. 63-77, 2 figs., 1 chart.

STANDARDIZED SPECIFICATIONS FOR LUBRICATING OILS, C. W. Stratford. Discussion of possible standard specifications for lubricating oil. As regards the stability of oils, the writer considers the oxidation test the only dependable and satisfactory one. The main facts shown by this test are the evaporation loss and the rate at which solid hydrocarbons are formed by polymerization or precipitation when oils are exposed to working conditions of an engine.

Distillation of finished oils under a high vacuum offers an unfailing means of determining their situation, that is, of what groups of hydrocarbons highly volatile or less volatile the finished oils may consist.

The various tests are described in detail, and the properties of representative American lubricating oils for use in internal combustion engines are given in a table.

It is stated that the investigation here discussed was carried out at the suggestion of the chairman of the Automotive Products Section of the War Industries Board. (*Aerial Age Weekly*, vol. 7, no. 1, March 18, 1918, pp. 48-51, 4 figs.)

JOINTS AND JOINTING MATERIAL. *The Engineer*, vol. 125, no. 3245, March 8, 1918, pp. 212-213. The subject of jointing materials, both plastic and sheet packing, is discussed in detail, as well as such metallic joints as those of lead wool.

VALVE CAMS, Ernest G. Ritchie. Notes on the design of three types of valve cams—(1) a cam giving constant rate of change of acceleration, (2) a cam giving constant acceleration, and (3) a tangential cam.

The investigation here described indicates that a cam designed to give constant rate of change of acceleration has many advantages, and it should result in much "sweeter" motion of the valve gear, giving longer life of the moving parts. Also, it should result in higher volumetric efficiency so far as the engine itself is concerned. (*The Automobile Engineer*, vol. 8, no. 111, February 1918, pp. 34-36, 7 figs.)

FRICTION CLUTCHES, Herbert L. Towns. *The Automobile Engineer*, vol. 8, no. 3, February 1918, pp. 54-59, 12 figs. Paper presented to the Coventry Branch of the Graduate Section of the Institution of Automobile Engineers. The design of the various types of clutches is described in considerable detail.

Machine Shop

ANNEALING BY MUFFLE AND POT OVENS COMPARED, Jos. B. Deisher. Discussion of carbon losses in these two methods of treating malleable iron and data of tests made in this connection.

The writer points out that in the matter of annealing temperatures for malleable cast iron much depends on the chemical composition of the hard iron.

For many reasons it is often desirable to run the temperature considerably higher than 1400 deg., the maximum and minimum temperatures of annealing being in the case of pot ovens 1650 and 1450 deg. fahr., and in the case of muffle ovens 1700 and 1500 deg., respectively. Further, exhaustive tests have shown that prolonged annealing has no detrimental effect on the physical strength of the product unless the temperature is run too high, and it is safe to say that more poor malleable cast iron is produced by underannealing than by overannealing.

For reasons not generally announced it has been found necessary to hold castings at annealing temperature from 60 to 72 hours before the cooling process is commenced. Otherwise, the result will almost invariably show that the iron carbide has not been completely dissolved, this combined carbon causing brittleness.

The writer believes, however, that 60 hours are not actually required to dissolve the iron carbide and that its dissolution is largely a matter of heat penetration, particularly where the muffle-type oven is used, while in the pot oven there is little doubt but that the nature and composition of the packing material affects the dissolution of the iron carbide.

An opinion is expressed that had annealing temperature been made as high as the casting would stand at the beginning of the anneal, then the casting withdrawn before 60 hours of annealing had been completed and cooled very slowly, the result would doubtless have shown that a greater percentage of the carbon had precipitated as graphite. The writer recalls an incident where by accident the arch forming a muffle chamber in a muffle-type oven fell in and the fire had to be shut off about 36 hours before the regular time. The stack chamber and the oven were sealed up practically airtight and allowed to cool down as slowly as possible with the result that when the oven was opened the castings were found to be fairly well annealed. The carbide appeared to be completely broken up, but there was scarcely a trace of decarbonization visible without the aid of a microscope, which the writer ascribes to the fact that the annealing temperature was high when the accident occurred while the cooling was extremely slow, thus allowing plenty of time for the precipitation of graphite.

In the estimation of the writer, aside from the absolute necessity of first completely dissolving the iron carbide, the rate of cooling is of the utmost importance, particularly where it is desired to complete the annealing process in the shortest time possible. The writer recommends the following practice: To reach the highest temperature at the beginning of the anneal and hold it until the iron carbide is dissolved; then gradually dropped to 1400 deg., which, besides favoring the precipitation of graphitic carbon, would also lessen the danger of warping.

TABLE 1 COMPARATIVE RESULTS ON POT-OVEN AND MUFFLE-OVEN ANNEALING

	Pot Oven		Muffle Oven
	Mild packing	Strong packing	Without packing
Total carbon in hard iron, per cent	2.63	2.63	2.63
Combined carbon after anneal, per cent	0.53	0.13	0.05
Graphitic carbon after anneal, per cent	1.75	1.85	2.12
Total carbon after anneal, per cent	2.28	1.98	2.17
Total carbon removed in anneal, per cent	0.35	0.65	0.46
Wedge test, length of butt in inches	2⅞	2¾	2
Tensile strength, lb. per sq. in.	49,448	50,044	49,542
Elastic limit, lb. per sq. in.	38,746	37,122	37,398
Elongation, per cent in 2 in.	6.3	6.7	7.3

As regards the comparative advantages and disadvantages of muffle ovens, the principal advantages in favor of the muffle oven are: elimination of labor required to pack, handle and shake out the pots; cost of packing material; expense of renewing pots, etc. The disadvantages are: longer time required to bring the casting to annealing temperature; the castings are more apt to become warped or distorted. There is more danger of the castings becoming scaled due to the air leakage into the muffle and finally, small and delicately constructed castings cannot be annealed in this type of oven at all, unless they are packed in trays.

Table 1 gives the comparative results of pot-oven and muffle-oven annealing. (Paper presented at the Boston Convention of the American Foundrymen's Association, abstracted through *The Foundry,* vol. 46, no. 308, April 1918, pp. 154-158, *cp*)

The Salvaging of High-Speed Steel. *The Iron Trade Review,* vol. 62, no. 14, April 4, 1918, pp. 845-848, 16 figs. Popular description of some practical methods for conserving high-speed steel, including the discussion of electrically welded tools and the use of formed cutters.

Machine Tools

Manufacture of Machine Tools in Switzerland, C. E. Carpenter. It is said that the machine-tool industry of Switzerland has experienced a phenomenal growth since the beginning of the war. Tools of many types and sizes are being produced in large quantities, but the supply is not equal to the demand. In particular, exportation of machine tools has increased by leaps and bounds.

The types of machines which have figured most prominently in Swiss exports during the last years are engine lathes up to 24-in. swing and 12 to 15 ft. between centers, turret lathes up to 2-in. spindle capacity, bench precision lathe, thread milling machines for fuse work and shells, universal milling machines and grinding machines.

The various types of machines exported are briefly described. (*American Machinist,* vol. 48, no. 12, March 21, 1918, pp. 485-486.)

Making Concrete Metal-Planing Machines, Ethan Viall. *American Machinist,* vol. 48, no. 15, April 11, 1918, pp. 603-608, 15 figs. Description of a strikingly novel type of metal planing machine. A more detailed abstract of this article will be presented in an early issue.

Measurements and Testing

An Electromagnetic Clutch Indicating Device, V. Karapetoff. *Automotive Engineering,* vol. 3, no. 3, March 1918, pp. 101-104, 3 figs. Description of an indicating device designed especially for use on the Entz magnetic transmission in motor cars, such as used on the Owen magnetic car.

Erichsen Tests on Aluminum Sheets, Robert J. Anderson. Data of tests with the Erichsen ductility testing apparatus on annealed No. 18 gage aluminum sheets.

The Erichsen apparatus consists essentially of a die and holder for holding the sample to be tested and the internal tool actuated by a hand wheel which moves gradually forward until the sample is ruptured. The progress of the internal tool and the ultimate factor are observed in the mirror and the depth of indentation is read directly from a micrometer-graduated screw.

One of the distinctive features of this test is the evidence of approximate grain size of the metal tested which the fractured domes of the test pieces indicate. Particularly is this test of value as a guide to drawing operations on annealed metal. Under-annealed metal will rupture by deep draws, owing to its hardness and lack of ductility, while over-annealed metal will also rupture because of the weakened condition of the metal resulting from large grain size. The domes of the Erichsen test pieces indicate at once how a given metal may be expected to behave in the draw press, because, in fact, the apparatus is itself a miniature draw press. Mechanics

Some Fundamentals of Rolling Support, F. W. Gurney. A general discussion on the subject of bearings and their construction, including a comparison between ball bearings and roller bearings. The matter of increasing the area of contact between the ball and its raceway is discussed in some detail.

There is a limit to the closeness with which the race curvature may approach the curvature of the ball. In large bearings for carrying great loads at slow speeds the race contour is made very much closer than in high-speed bearings. In one case the chief consideration is load capacity; in the other, the consideration of load is practically negligible, but the reduction of friction is of supreme importance. Increasing the curvature of the race is one of two ways of increasing the available area of contact between the ball and its raceway. In ordinary practice the race curvature may be increased to an extent that will multiply the capacity of the ball many times before objectionable friction is incurred, but close race curvature spells safety for the bearing. In fact, the ball bearing made with close race contour is in effect a roller bearing. In it there are realized ample areas of contact which the advocates of the roller bearing particularly emphasize as an advantage. Munitions

New Pressure Table for Eley Lead Crushers, F. W. Jones. In the determination of shotgun pressure the Eley lead-crusher tables play a most important part. In fact, lead crushers are very convenient for testing of pressure in many kinds of rifles. They were not usually employed with military rifles because of the inconsistencies of results obtained with pistons of various sizes, which hitherto could not be properly explained. Some fifteen years ago an attempt was made to replace lead crushers by coppers of a special conical form, the object of this change having been to utilize the material for which exact calibration was possible. These crushers were given several years' trial in all the important testing stations in England, but ultimately they had to return to lead.

In 1913 a series of experiments on a very large scale was initiated for the purpose of building up a new table for Eley lead crushers. The process underlying these experiments was the taking of simultaneous records from pistons of alternative diameters. The pressure curve was worked out step by step in so many pairs of places that the resulting table must be accepted for all time as beyond dispute. It was not proved, and a fact that could not be proved at the time was whether the scale of tons pressure was correct or not. There were good reasons for believing that it was not correct, but as absolute values were not available the conventions of estimate were allowed to remain. Hence, the 1913 table gave all pressures in true proportion, but the real values could only be obtained by applying throughout a multiplier, which, at that time, was unknown.

Recently H. W. R. Mason revealed the data which explain the previous experience with lead crushers and provide figures for their exact calibration. He discovered that lead crushers developed a resistance during compression which varied with the amount of decrement, but was independent of the means by which the decrement was brought about. Whether the lead is squeezed in a press or reduced by the ordinary method of compression in a proof barrel, equal resistances are set up for equal decrements. The excess resistance developed by lead is transient and it disappears inside of 5 min. of decrement greater than 0.050 in. Thus, lead which is hardened by compression no matter to what degree, recovers to what may be termed the dead-soft condition inside a period of a very few minutes. In other words, it possesses the property of spontaneous annealing.

The rate at which this temporary hardness disappears grows with the degree of decrement and hence with the degree of resistance developed. For example, the dead-soft condition of a lead crusher compressed from 0.500 in. to 0.400 in. is reached in a period of 5 min. Whereas, the lead compressed to 0.340 in. recovers in the fraction of a minute. Tests of crushers which were made in ignorance of these facts were necessarily inconsistent, because nobody ever dreamed that time variations between successive treatments introduced so disturbing an influence. Now, however, when these conditions are understood, lead crushers may be tested by the simplest of all methods—that of the dropped weight.

The successive decrements produced by the repeated application of the same blow will not supply a true impact table of resistances, the reason being that the resistance developed by the initial blow has disappeared wholly or in part before the second can be delivered. Thus, three blows delivered in succession produce a greater total effect than the same three blows would do if they could be repeated so quickly that the lead had no time to anneal in the interval. In other words, three blows under practical conditions of experiment are not the equivalent of three times one blow. A true resistance table derived from impacts can be obtained by blows varying in amounts. For example, lead crushers may be submitted to blows of one, two, three, etc., pounds in successive series, and the difference in decrements between any two qualities of blow are those which would exist between successive blows by the same weight, supposing the disturbing effect of the time interval could be eliminated. The fact that it cannot is of no present concern, bearing in mind that alternative methods get around the difficulty. What is important is to realize that a succession of blows gives misleading results and should therefore be avoided.

Common sense supports the decision arrived at, for the ultimate object is to estimate powder pressure, and as powder produces its result in one continuous movement the method of calibration may be accepted which repeats this condition as nearly as may be. In point of fact, the time taken by a 3-lb. weight dropped from heights of 1 in. to 24 in. to compress the

crusher is about the thousandth part of a second. Again, the difference between the times of compression of 1-ft-lb. and 2-ft-lb. blows is less than the ten thousandth part of a second. The loss of hardness, or what is more aptly termed the error due to spontaneous annealing, may be ignored when dealing with such small time intervals—time intervals which are less than the period of duration of pressure in a shotgun proof barrel.

Mr. Mason made measurements of the decrements of Eley lead crushers from the drop of a 3-lb. weight released from nine different heights between the limits 1 in. and 24 in. The details having been published in these columns, it is now only necessary to assemble the results as in Table 2. For convenience, they may be stated with reference to a piston of 0.225 in. diameter. In that form they stand as pressure. Pressure can be converted into dead load by multiplying by 89.06, which is the product of one ton stated in pounds and the area of the piston. The word "resistance" has the same significance as "dead load," but it is more scientific because it better conveys an idea of the properties of a crusher in reference to the load it can support, for it can only support a given load provided it can bring to bear an equivalent value of resistance against the force seeking to compress it.

TABLE 2 RESULTS OF IMPACT EXPERIMENTS WITH ELEY LEAD CRUSHERS

Remaining length, inches	True pressure for 0.225-in. piston	Multiplier which gives agreement with Eley 1913 Table
0 4920	2 15	1 156
0 4779	2.77	1 130
0.4668	3.40	1 196
0.4572	3.66	1 172
0 4375	4.52	1 248
0.4104	5 60	1 302
0 3878	6.45	1 325
0.3678	7.12	1 332
0 3496	7.78	1 345

In the third column of this table there is no evidence of the equal multiplier which converts the Eley 1913 Pressure Table into absolute pressure values. As a matter of fact, there should not be, and this for reasons which must be carefully explained. According to the Eley table a remaining length of 0.3678 corresponds to a pressure 2.18 times greater than that corresponding to a remaining length of 0.478 in. The impact results by contrast show a ratio of 2.57 times for the same basic values. It has previously been stated that the Eley table conforms within itself, that is, one part with another, beyond all question of doubt. A much smaller testimonial has been accorded to the values arising out of Mr. Mason's experiments. No further sets of experiments are likely to be conducted which could compete in range and the exactitude with those upon which the Eley table is based. The appearance of disconformity of the impact results with the values of the Eley table must, therefore, be open to explanation, and the explanation is that the above impact results show the effect of resistance of statical loads, whereas in shotguns the pressure is applied in the manner known as dynamical.

The crusher may be loaded absolutely statically or absolutely dynamically, or any intermediate condition may exist between the two. In copper crushers an effort is made to eliminate dynamic tendencies and generally, if a crusher could be so designed that it would respond instantaneously to the applied pressure, its readings could be translated by a statical scale.

The writer discusses in detail the determination of pressure by means of a piston. In view of the irregular pressure given by shotgun cartridges an empirical rule had to be formulated for extracting real pressure results from the obviously excessive readings which followed when insufficiently compressed coppers were employed in connection with cartridges giving unexpectedly high results. The rule was to regard all pressure registered by decrements of 0.020 in. or under as true, while all decrements beyond this limit were treated as being in excess to the extent of half the surplus over 0.020 in. This rule proved of great assistance in tests with coppers and demonstrated that conical copper crushers under the conditions of use presented in shotguns are loaded partly dynamically, which may involve possible errors in the use of a table based on static behavior. The Eley table is, however, wholly dynamical and hence the figures of pressure do not represent the actual resistance of the crusher, though it is possible to obtain from a dynamical table a series of true dead-load or resistance values. By means of a rather complicated process, described in the

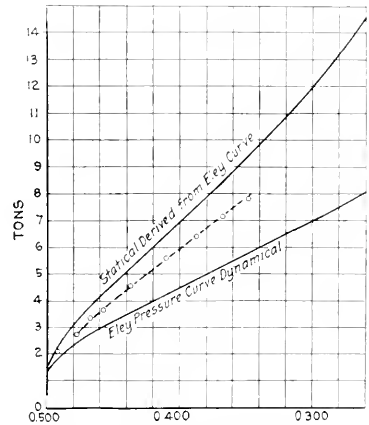

Fig. 10 Eley Lead Crushers, Pressure on a 0.225-in. Piston

original article, two curves were derived as shown in Fig. 10. The lower curve is that of the Eley table, from which the top one was derived. The resistances are shown for convenience as pressure on a 0.225-in. piston. Dynamical and statical curves for the same crusher are thus shown in contrast, and between them is another curve showing the resistances obtained from the drop-weight experiments. This curve shows that when a pressure was called 3 tons, it was, in reality only 85 per cent of 3 tons, or 2.55 tons. It must be decided in the future whether so much fiction can be allowed in a measurement which is otherwise fundamentally sound. The statical equipment of the Eley curve with the above correction becomes a dot curve in the figure, which agrees with the results of the drop-weight experiment to a very considerable extent. Power Plants

Tamarack Mills Power Plant, Charles H. Bromley. Describes the chief features of the new oil-burning plant furnishing light, heat and power to the Tamarack Mills, Pawtucket, R. I. The plant was designed solely for fuel, has a 2500-kw. extraction turbine, heats the mills with forced-circulation hot water and has the largest atmospheric cooling tower in New England. Unusually interesting performance figures are given. (*Power*, vol. 47, no. 13, March 26, 1918, pp. 426-430, 6 figs.)

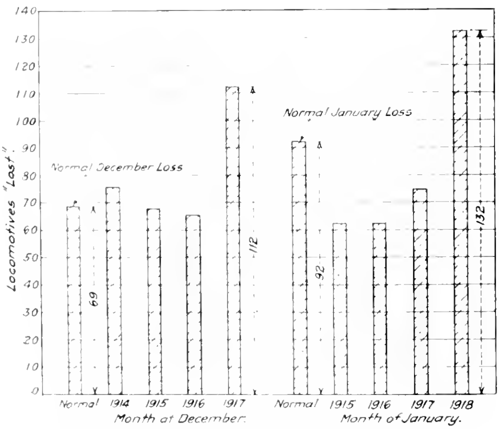

Fig. 11 Estimated Effect of Winter Temperatures on Train Resistance Stated in Terms of Loss of Use of Locomotives. (N. Y., N. H. & H. RR.)

Pumps

Tests of Main Circulating Pumps of the "North Dakota" and "Nevada," Commander S. M. Robinson, U. S. N. Data of tests of the main circulating pump of the *Nevada*, carried out on board ship, and of the *North Dakota*, made by the Fore River Shipbuilding Company, and carried out partly ashore and partly on ship.

The paper presents a complete description of the method of carrying out the tests, and gives the data in the form of curves and tables.

Several points of design were brought out in these tests. Thus, when the *North Dakota* was placed in commission it was found that there was a sharp corner in the volute casting on the discharge side of the pump. This caused considerable vibration in the pump, which disappeared when the corner was removed. Another point in connection with the design of circulating pumps for use in connection with condensers on board ship referred to head and capacity conditions. The ordinary marine practice is to specify the head only approximately and to allow what is considered to be a liberal supply of circulating water. In the choice of the head an approximate figure is taken, no attempt being made to calculate the head from the actual condenser and piping, the result being that if the actual head varies considerably from this, the pump efficiency may be very low even with a good pump. This effect will be exaggerated if the water used is much less than the design calls for. The variation in the total head of condensers for the same horsepower is much greater than is commonly supposed. Thus, the total head at the same capacity is about three times as great for the *North Dakota* as it is for the *Nevada*. An attempt was made to analyze the various parts of the total head. (*Journal of the American Society of Naval Engineers*, vol. 30, no. 1, February 1918, pp. 23-40, illustrated, *e*)

Railroad Engineering

Winter Temperatures and Locomotive Capacity, W. L. Bean, Mem.Am.Soc.M.E. The unusually severe temperatures of the past winter have offered an opportunity to study the influence of decreased temperatures on the efficiency of steam locomotives. A drop in temperature decreases the capacity of the steam-locomotive boiler and also greatly increases the train resistance, the latter because journal friction increases as the temperature falls, owing to the increase in the viscosity of the lubricant. In fact, the first factor appears to be of much less importance than the latter.

Operating records in electric freight service between Harlem River terminals and New Haven, a distance of approximately 70 miles, with undulating curves of 0.6 per cent and considerable curvatures, afforded an opportunity to compare the consumption of power in winter with that of summer in a better manner than could have been done with steam locomotives.

The article explains in detail how "power-range" and "temperature-range" curves were found and compared. It was found that for each degree of temperature fall the demand for power increases 0.65 per cent.

This figure has been found from data secured with electric locomotives, but it is believed that the factor 0.65 per cent may be applied to steam-locomotive service as well, because there is no great difference in the heat losses and engine friction of steam and electric locomotives considered in percentage of maximum capacity, and heat losses in steam locomotives causing reduction in capacity in winter as compared with summer are practically offset for the purposes of this investigation by the consumption of current in heating cabs of electric locomotives, which latter required approximately 3 per cent of the total electric power used on a trip.

On the basis of the 0.65 per cent greater power required to move cars for each degree of temperature drop, excess-power requirements in last December and January as compared with those months in the three preceding years were as follows:

December, 1917

4.55 per cent greater than in December, 1914
5.55 per cent greater than in December, 1915
5.95 per cent greater than in December, 1916

January, 1918

8.71 per cent greater than in January, 1915
8.71 per cent greater than in January, 1916
7.15 per cent greater than in January, 1917

Assuming 800 locomotives normally in service, the result of such handicap, measured in the number of locomotives necessary to make up the increased demand for power on account of low temperature, was as follows:

December, 1917	January, 1918
36.4 engines more than in 1914	69.7 engines more than in 1915
44.4 engines more than in 1915	69.7 engines more than in 1916
47.6 engines more than in 1916	57.2 engines more than in 1917

Fig. 11 indicates the number of engines which would have to be added in a normal December and in a normal January to make up the loss of engines due to winter temperatures as compared with summer.

The writer calls attention to the fact that the foregoing estimates are based exclusively on the effect of low temperatures in causing increased resistance of trains through increased friction in bearings and increased heat losses in steam locomotives. There are numerous other ways in which low temperatures delay train operation and reduce the efficiency which have not been taken into consideration in the present instance. Research

The Research Couplet. Research in Pure Science and Industrial Research, Wm. Allen Hamor. The writer discusses the interrelation between pure science and industrial research and expresses the view that the fundamental differences between pure research and industrial research are traceable to the differences in the poise and personality of the representatives of each type of scientific investigation.

With special regard to chemistry, it is pointed out that the great triumphs of pure chemistry are philosophic achievements, while all the conspicuous accomplishments in the domain of chemical industry are the outcome of the application of channels of knowledge explored by the investigators in pure chemistry.

An interesting classification of research in pure chemistry and in applied chemistry is offered.

Next comes research as developed by corporations. This appears to move through more or less well-developed stages according to the character of the industry. These stages may be presented as follows: First, research applied to the elimination of difficulties in manufacturing, and at least six American organizations have sixty or more research chemists engaged in this field of industrial research.

Next comes research having some new and specific commercial object. Frequently the appreciation of a need in industry for some new tool, method or material stimulates a deliberate search for means to satisfy that demand; or, again, it is sought to produce a commodity imported from another country or locality. This field of research proved especially profitable since the beginning of the war. Among the most progressive firms there is a growing appreciation of the fact that almost every discovery in science may ultimately have influence on industry. This leads to researches in pure science with no specific commercial application in view. This kind of research can be carried out only by large corporations, such as the General Electric Company, the Eastman Kodak Company, etc. It is a very far-seeing business policy directed to outstrip competition by the continuous provision of discoveries, which may sooner or later be turned to industrial account.

Research for the purpose of establishing standard methods of testing and standard specifications connected with the purchase of raw materials is a very important field of investigation, the necessity for which is obvious. (*The Scientific Monthly*, vol. 6, no. 4, April 1918, pp. 319-330, *g*)

Aerodynamic Laboratory of the Leland Stanford Jr. University, Wm. F. Durand, Mem.Am.Soc.M.E. Description of this laboratory and its equipment, with special reference to tests on air propellers.

The purposes of the investigations for which the laboratory was designed were as follows:

First, the development of a series of design factors and coefficients drawn from model forms, distributed with some regularity over the field of air-propeller design and intended to furnish a basis of check with similar work done in other aerodynamic laboratories, and as a point of departure for the further study of special or individual types and forms.

Second, the establishment of a series of experimental values developed from models and intended for later use as a basis for comparison with similar results drawn from certain selected full-sized forms and tests in free flight.

The so-called Eiffel type of wind tunnel was adopted, described in some detail in the report.

An interesting feature of the design is constituted by the device for securing uniformity in flow into the test chamber from the mouth of the collector. With this in view a honeycomb structure was built in the delivery end of the collector. It is composed of hexagonal cells 3 in. in diameter and 10 in.

long made of roofing tin and soldered at the edges. This forms a stiff and true structure with thin walls presenting the minimum resistance to the flow of the air.

The form of the collector and diffuser tubes was determined by circular frames made by nailing up a double ring of $\frac{7}{8}$-in. board segments, sawn to the proper curvature on one side, thus forming a strong ring of wood $1\frac{3}{4}$ in. thick. These rings were then fastened to uprights made of 2-in. by 4-in. scantling spaced about 2 ft. between centers and so adjusted vertically as to line up with the axis of the tunnel about 8 ft. 9 in. above the floor of the room. These circular rings, spaced out in this manner and each of appropriate diameter, give thus a series of transverse sections of the tunnel. The next step was to run longitudinal battens $\frac{7}{8}$ in. thick by 2 in. wide along the inside of these rings, spacing them equally around the circumference. These battens were spaced about 6 in. between centers at the small end and 12 in. at the large end. This entire framework, when set up, cross-braced and stayed to the building, roof and floor, made a very stiff and secure skeleton on which to lay the inner covering forming the shell of the tunnel itself. This covering was of a good quality of heavy cotton sheeting laid on and stretched with care and secured along each longitudinal batten and running on the inside a small airplane batten approximately $\frac{1}{4}$ in. thick at the center by $\frac{3}{4}$ in. wide, thus holding the fabric down on the large battens.

The fabric was then treated with a standard airplane wing "dope" (celluloid dissolved in acetone), varnished and rubbed down to a smooth finish. At the propeller-fan end for a distance of about 4 ft. the number of longitudinal battens was doubled and for a distance of $1\frac{1}{2}$ ft. the inside of the tunnel was covered with galvanized sheet iron in order to give necessary stiffness in the immediate vicinity of the tips of the blades of the fan. This general procedure gave a tunnel with a smooth, true and fair surface, conforming to the law of cross-sectional areas as determined, and, as later test showed, stable and without sensible vibration or disturbance under the highest wind velocities employed.

The experiment room was made of matched boarding laid on the inside of joists and studding spaced about 18 in. between centers. The highest wind speeds contemplated were not much about 60 m.p.h., and with a reasonable coefficient of flow through the collector tube this would require a reduction of pressure in the experiment room not much exceeding 10 or 12 lb. per sq. ft. This is a very moderate load, and no trouble was experienced in carrying it with ordinary framing covered with the matched boarding as indicated. To give light in the experiment room, two window sashes were fitted and the glass was reinforced on the inside with supports, reducing the size of the pane to the equivalent of about 9 in. by 10 in.

The room was made practically airtight by papering on the inside with heavy builders' paper laid on with a specially heavy paste. For entry and exit an airlock was provided with doors closing on suitable packing strips and fitted with self-adjusting hinges, allowing close contact between door and packing.

The air speed is measured by a pitot tube of the usual type. There is, however, also a sensitive pressure indicator showing the pressure head between the experiment chamber and the surrounding room, thus serving as an instantaneous air-speed indicator.

This pressure indicator consists of two manometric cells carried each on opposite ends of a sensitive balance. The lower ends of the cells dip under coal oil, the space above the liquid being connected in one case to the air in the experiment chamber and in the other, to the air in the surrounding room. The zero position of the scale is determined with both cups connected to the outer room. With one connected to the experiment room the balance becomes disturbed and the weights added to restore equilibrium furnish a direct measure of the depression within the experiment room. These indications calibrated against the pitot-tube measures of speed give the direct relation desired between the measure of the depression and the air speed at the propeller position. The weights for the balance were so selected as to give readings of pressure directly in pounds per square foot.

A relation was found based on pitot-tube determinations of velocity and manometric-balance measures of difference of pressure acting as an air head. This relation was found to be practically constant and equal to

$$\text{Velocity head} = 0.876\ (P_1 - P_2)$$

where P_1 and P_2 denote the pressure heads without and within the experiment room.

An interesting telephonic torque dynamometer is described in the same report. (*Journal of the Society of Automotive Engineers*, vol. 2, no. 3, pp. 230-238, 14 figs., *d*)

Refrigeration

Economy of the Refrigeration Power Plant, Victor J. Azbe. *A. S. R. E. Journal*, vol. 4, no. 4, January, 1918, pp. 368-387, 11 figs. A discussion of the various sources of losses in a refrigeration power plant, with suggestions as to how such losses may be reduced or eliminated.

Heat Balance of the Ammonia Compression System, J. H. H. Voss. For determining the economy of the ammonia-compression system three values are required: first, the external work or indicated horsepower expended in the compressor which may be determined from the indicator card; second, refrigerating effect; and third, the heat of condensation. Graphical methods are given for the determination of these three factors. (*A. S. R. E. Journal*, vol. 4, no. 4, January, 1918, pp. 345-367, 13 figs.)

Steam Engineering

Boilers with Air Heaters. Description of an installation where an air heater is provided for each boiler.

The installation described contains a 3000-kw. turbo-alternator driven by a turbine. There is one chimney for each four boilers and an air heater for each boiler.

The air is supplied to the air heater through a duct, Fig. 12, leading from the main generator in such a way as to utilize the heat of the air from the generators. It is heated to a comparatively high temperature in passing through the air heater, and from thence to the suction inlet of the fans, from which fans it is discharged to the Underfeed Stoker traveling grates.

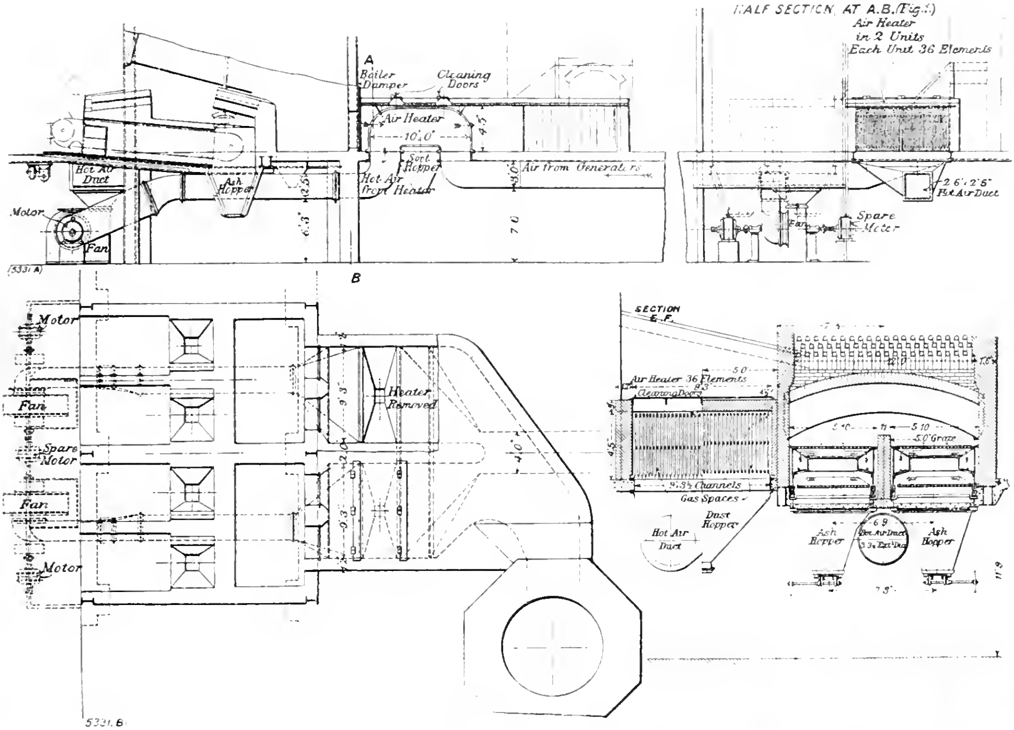

Fig. 12 Usco Air Heaters and Traveling-Grate Stokers

The air heaters, as illustrated, each comprise 36 elements between which the hot gases of combustion flow from the boiler to the main flue. The warm-air main from the generators is splayed into 36 inverted U-branches. Each branch is further divided by a diaphragm to equalize the flow in the upper and lower portions. The total length of an element is 10 ft. and the depth 4 ft. 5 in., while the width of each heater chamber is 9 ft. 3 in. Below the heater there is a dust hopper, and above it there are cleaning doors.

The warm air is drawn into and through each heater by a fan driven by an electric motor. To guard against stoppages, a spare motor is provided in addition to individual motors for each fan. (The original article gives extracts from the specification, showing the extent and requirements of the plant). (*Engineering,* vol. 105, no. 2722, March 1, 1918, pp. 228-230, 5 figs., *d*)

Boiler Baffles of Plastic Material. As a substitute for baffles for water-tube boilers consisting of tile, bricks or blocks of refractory material fitted in between the tubes, a composition is offered of refractory materials shipped in barrels in a plastic condition ready for use.

It is claimed that with this new material it is possible to secure jointless and gas-tight baffles, since the coefficient of expansion is so small that the change in shape due to variation of temperature may be neglected.

In forming a cross-baffle for a water-tube boiler of the Babcock & Wilcox Company type, the cast-iron baffle plate is employed as one side of the mold, while the other is formed by thrusting slats into the diagonals between the tubes, as illustrated in Fig. 13. The plastic material is then poked down through the diagonals to fill the space between the baffle plate and the slats, the material being sufficiently plastic to fit the tubes snugly. The boiler is then fired up slowly so that the slats will burn out while the plastic material is being dried and vitrified in place. (*Iron Age,* vol. 101, no. 12, March 21, 1918, p. 743, 1 fig., *d*)

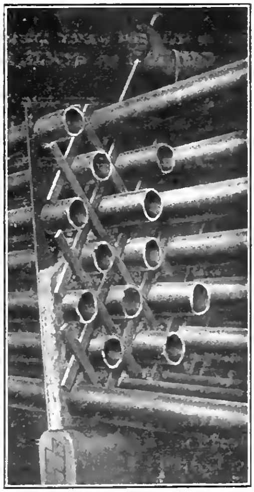

Fig. 13 Method of Putting In Boiler Baffles of Plastic Material

Increasing the Life of Economizers. With particular regard to New England, the average life of an economizer is from thirteen to eighteen years, depending on local conditions. After that the tubes become so thin that they are liable to fracture. This liability to fracture is greatly increased by any sudden shock, such as a water hammer, and, in fact, it is impracticable to carry the usual high boiler pressures.

The present article describes an arrangement for use with these older economizer installations whereby they may be protected from sudden shocks and excessive pressures.

The water is pumped from the primary heater through one stage of the chamber to the economizer at about 10 to 50 lb. pressure, and then from the outlet of the economizer to the suction of the second stage of the pump, where the pressure is increased to the required boiler pressure. See Fig. 11.

The application of this type of pump is said to have increased the life of several economizer installations. In one case where the repairs had become excessive a pump of this type was installed and the pressure cut down from 175 to 40 lb., which prolonged the life of the machine for a period of four years and eliminated practically entirely all the repairs due to tube and header fractures. (*Power*, vol. 47, no. 13, March 26, 1918, pp. 436-437. 1 fig., *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

BOOKS AND MORE BOOKS

OUR soldiers and sailors here at home in the training camps, on transports, in the Navy and overseas in the trenches are urgently in need of good books. From every camp librarian we receive reports of a steady and large demand for technical works of every class. The need for engineering data is especially acute.

Over 600,000 books are now in use, but hundreds of thousands more are needed. Standing unused on shelves in our homes are many good books that would be of inestimable value in the camps. Office shelves bear books, seldom if ever touched, whose presentation to the Army would be a real service. Obviously, technical books sent should be recent editions.

The fund of $1,700,000 raised by the American Library Association to build and equip thirty-four libraries in the camps, to provide trained library service and to buy books, will not be adequate unless substantially reinforced by gifts.

To present books, all that is necessary is to mark them "War Library Service" and deliver them at any public library. They will be forwarded to the war-library storage plant and distributed to the points where they are most needed.

BOOK NOTES

Aids in the Commercial Analysis of Oils, Fats, and Their Commercial Products. By George Fenwick Pickering. J. B. Lippincott Co., Philadelphia, 1917. Cloth, 6x9 in., 133 pp.

Intended as a guide in works laboratories. The tests for determining the purity of the substances and their suitability for various purposes are given, together with tables of constants for each. These values, the author states, are here published for the first time.

Automobile Welding with the Oxy-Acetylene Flame. By M. Keith Dunham. A Practical Treatise Covering the Repairing of Automobiles by Welding, with a Non-Technical Explanation of the Principles to be Guided by in the Successful Welding of the Various Metals. The Norman W. Henley Publishing Co., New York, 1917. Cloth, 4x6 in., 167 pp. $1.

A manual for workmen which explains in simple language the principles of welding, and describes in detail their application in automobile repairing.

A Bibliography of the War Cripple. Compiled by Douglas C. McMurtrie.
The Economic Consequences of Physical Disability. By John Culbert Faries. A Case Study of Civilian Cripples in New York City.
Memorandum on Provision for Disabled Soldiers in New Zealand. By Douglas C. McMurtrie. N. Y. Red Cross Institute. New York, 1918. Paper, 8x11 in.

These pamphlets form the first three numbers of the publications of the Red Cross Institute for Crippled and Disabled Men. The bibliography covers 39 pages and will be further extended by supplements as new material accumulates.

Broaches and Broaching. By Ethan Viall. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6x9 in., 221 pp., 188 illus. $2.

A summary of the present development of broaching work and machinery, written primarily to enable those interested to judge whether it is applicable to their particular class of work or not, and to provide working directions in the former case. Contents: Broaching and Broaching Tools; Standard Types of Broaching Machines; Examples of Pull Broaching Work and Practice; Examples of Push Broaching Work and Practice; The Design of Pull Broaches, The Design of Push Broaches, Making Broaches.

Brown's Directory of American Gas Companies, 1917. Compiled and Corrected Annually by E. C. Brown. The Gas Age, New York, 1917. Cloth, 7x11 in., 897 pp. $5.

This edition summarizes the statistics of 1179 manufactured, 768 natural, 134 acetylene and 70 gasoline gas companies, 161 parent or operating companies and 47 public service commissions. An appendix includes the financial data of 277 companies, the officers, directors and committees of gas associations and an alphabetical list of gas association members, with their company and association affiliations.

The Calorific Power of Fuels. By Herman Poole. With a Collection of Auxiliary Tables and Tables Showing the Heat of Combustion of Fuels, Solid, Liquid and Gaseous. 3d ed., rewritten by Robert Thurston Kent. John Wiley & Sons, Inc., New York, 1918. Cloth, 6x9 in., 267 pp., 65 illus. $3.

The introduction of new fuels, the improvements in the methods of investigating the calorific power of fuels and the increase in the amount of available accurate data have made it necessary to rewrite the book. The latest researches have been incorporated, inaccurate data occurring in earlier editions have been eliminated and the results have generally been reported in the English system of units instead of in the metric system used in former editions.

Chemical Patents and Allied Patent Problems. By Edward Thomas. John Byrne & Co., Washington, 1917. Cloth, 6x9 in., 58 pp. $2.50.

This work is intended to provide a statement of the law of the chemical patents, together with a practically complete list of the cases on which it is based, and of the principal cases intimately related in reasoning to them. Written from the point of view of the patent attorney and the expert witness.

Dyes and Dyeing. By Charles E. Pellew. Robert M. McBride & Company, New York, 1918. Cloth, 5x8 in., 274 pp., 24 illus., 8 pl. $2.

This book describes the modern dyes in non-technical language, discusses the theory and practice of color dyeing, and describes the methods of dyeing various fabrics and materials. Various methods of coloring objects in patterns are also described. It is intended for use by craftsmen doing small scale work.

The Elements of Railroad Engineering. By William G. Raymond. 3d ed., revised. John Wiley & Sons, Inc., New York, 1917. Cloth, 6x9 in., 453 pp., 107 illus. $4.

This book attempts to describe the fixed portion of a railroad plant and to give the underlying principles of the design of its layout. The present edition has been largely revised and the introduction has been modified to conform to the progress that has been made in the study of valuation and regulation of utilities, the discussion of engine capacity and the chapters on signaling have been rewritten, and a chapter on the principles of valuation has been added.

Essentials of Volumetric Analysis. By Henry W. Schimpf. An Introduction to the Subject, Adapted to the Needs of Students of Pharmaceutical Chemistry, Embracing the Subjects of Alkalimetry, Acidimetry, Precipitation Analysis, Oxidimetry, Indirect Oxidation, Idometry, Assay Processes for Drugs, Estimation of Alkaloids, Phenol, Sugars, Theory, Application and Description of Indicators. 3d ed., rewritten and enlarged. John Wiley & Sons, Inc., New York, 1917. Cloth, 6x8 in., 366 pp., 61 illus. $1.60.

This edition is revised to accord with the new United States

Pharmacopœia, and improved by the additions of many new assay methods.

Farm Forestry. By John Arden Ferguson. John Wiley & Sons, Inc., New York, 1916. Cloth, 5x8 in., 236 pp., illus., 10 pl. $1.25.

A textbook on the care and management of farm woodlots and the utilization of their products, intended for use by students in agricultural colleges.

The Gas Engine Handbook. By E. W. Roberts. A Manual of Useful Information for the Designer and the Engineer. 9th ed. rewritten and enlarged. The Gas Engine Publishing Co., Cincinnati, (copyright 1917). Leather, 5x7 in., 315 pp., 80 illus. $2.

An epitome of gas-engine practice, in pocket book form, intended as a handy book of reference. This ninth edition has been revised to include present practice. Contents: Descriptive; Design; Operation, Testing, Selection.

Gas, Gasoline and Oil Engines. By Gardner D. Hiscox, revised, enlarged and brought up to date by Victor W. Page. 22d ed. A Complete, Practical Work Defining Clearly the Elements of Internal Combustion Engineering. Treating Exhaustively on the Design, Construction and Practical Application of All Forms of Gas Engines, Describes Minutely All Auxiliary Systems, Considers the Theory and Management of All Forms of Explosive Motors for Stationary and Marine Work. Includes also Producer Gas and Its Production. The Norman W. Henley Publishing Co., New York, 1918. Cloth, 6x9 in., 640 pp., 435 illus. $2.50.

The present edition of this work has been very thoroughly revised throughout, and an attempt has been made to include all recent developments of importance. New tables, formulæ and illustrations have been included and obsolete material has been eliminated, except when of historical interest.

Handbook for the .303-in. Vickers Machine Gun. (Magazine Rifle Chamber). Mounted on Tripod Mounting, Mark IV. George U. Harvey Publishing Co., Inc., New York, 1917. Linen, 3x5 in., 82 pp., 1 pl. 50 cents.

A catalogue in pocket size for those who are called upon to use this gun, written by a British army officer. Edited by Capt. S. A. Dion.

A Manual of the Processes of Winding, Warping and Quilling. By Samuel Kline. Of Silk and Other Various Yarns from the Skein to the Loom. John Wiley & Sons, Inc., New York, 1918. Cloth, 5x8 in., 134 pp., 20 illus. $2.

The preface announces this as the first American reference book on the technique of these branches of textile manufacture; and states that it is based upon long practical experience.

Mechanical Equipment of School Buildings. By Harold Alt. The Bruce Publishing Co., Milwaukee, (copyright 1916). Cloth, 8x11 in., 111 pp., 160 illus. $2.50.

A discussion of the various problems which arise in the design and installation of the equipment for ventilating, heating, lighting, sewage disposal, cleaning, toilets, drinking water, fire protection, etc., by an engineer with experience as a designing and supervising engineer.

Monthly Cost Accounting for Varnish Plants. By E. W. Story. National Varnish Manufacturers' Association, Philadelphia, (copyright 1917). Paper, 6x9 in., 51 pp. $1.25.

A detailed description of a method prepared at the request of the National Varnish Manufacturers' Association which the author believes will be adaptable to any varnish business.

Musketry. American Edition (.303 and .22 Cartridges), Elementary Training, Visual Training, Judging Distances, Fire Direction and Control, Range Practices, Individual and Collective Field Practices. By Captain E. J. Solano. Hand Grenades. Their Construction—Jam Tin, Hair Brush, Rifle Grenade, Service, Vaneless, Mexican or ... Grenade, ... Hair Brush, etc. By Captain S. A. Dion. George U. Harvey Publishing Company, New York, Inc., 1917. Linen, 4x6 in., 288 pp., 72 illus. $1.

A pocket size manual for officers and men.

Notes on Ballistics. Direct Fire, by Captain George A. Wildrick. High-Angle Fire, by Lieut.-Col. Alston Hamilton. 2d ed. Journal U. S. Artillery, Fort Monroe, 1917. Paper, 6x10 in., 99 pp., 9 illus., 2 diagrams. 50 cents.

Lieut. Wildrick's paper treats the problems that are most likely to be encountered at the battery, showing current methods of applying ballistic data to their solution. Lt.-Col. Hamilton presents the formulæ and methods used in ordinary ballistic computations for high-angle fire.

Oxy-Acetylene Welding Practice. By Robert J. Kehl. A Practical Presentation of the Modern Processes of Welding, Cutting, and Lead Burning, with Special Attention to Welding Technique for Steel, Cast Iron, Aluminum, Copper and Brass. American Technical Society, Chicago, 1918. Cloth, 5x8 in., 102 pp., 111 illus. $1.

A well-illustrated description of the methods and appliances in use, intended for the workman and superintendent. Contents: Welding Processes; Technique of Oxy-Acetylene Welding; Miscellaneous Oxy-Acetylene Processes; Examples of Automobile Repair; Costs.

The Petroleum and Natural Gas Register. A Directory of the Petroleum and Natural Gas Industries in the United States, Canada and Mexico. The Oil Trade Journal, New York, 1917-1918. Cloth, 9x12 in., 548 pp. $10.

Includes in one directory material on all branches of the petroleum and natural-gas industry. The work is based on statements made by officials of the companies listed, and gives the usually needed information as to properties, capital stock, officers, etc.

Practical Sanitation. By Fletcher Gardner. A Handbook for Practitioners of Medicine. C. V. Mosby Company, St. Louis, 1916. Cloth, 6x9 in., 418 pp., 46 illus. $4.

This handbook is intended to provide a plain non-technical exposition of the duties of a health officer by one familiar with his needs, experienced in the routine and emergencies of the local sanitary service. Published in a single volume. The second edition is thoroughly revised. An appendix gives schemes for sanitary survey of cities, public buildings and schools.

Railroad Structures and Estimates. By J. W. Orrock. 2d ed., revised. John Wiley & Sons, Inc., New York, 1918. Flexible cloth, 6x9 in., 579 pp., 272 illus. $5.

The author has rearranged the chapters in this edition to conform approximately with the classification of accounts as prescribed by the Interstate Commerce Commission in 1914, changed the prices to those which ruled in normal times, previous to 1915, has added much new material and, wherever possible, has given unit costs for all items of track work, track structures and buildings. A feature is made of quantities for track material.

Reference Notes for Use in the Course in Gunnery and Ammunition, Coast Artillery School. 3d ed. Coast Artillery School Press, Fort Monroe, 1917. Paper, 6x9 in., 123 pp., 19 illus. 50 cents.

A brief textbook compiled to meet the immediate demands of candidates for commissions in the Second Coast Artillery School at Fort Monroe.

Relief from Floods. By John W. Alvord and Charles B. Burdick. The Fundamentals of Flood Prevention, Flood Protection and the Means for Determining Proper Remedies. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6x9 in., 175 pp., 53 illus. $2.

The authors of this book have not attempted a treatise on flood relief, but have tried to outline briefly the general flood problem in all its many phases, to show what remedies can be applied and to point the way to the selection of the proper works. Technicalities have been avoided, with the hope that the matter may be understandable to readers who are not engineers. A table of great floods is given in the appendix.

SECRETARY OF THE SOCIETY, 1883-1906

PRESIDENT, 1906

HONORARY SECRETARY FROM 1907

SOME ECONOMIC ASPECTS OF FIRE-PROTECTION PROBLEMS AND HAZARDS IN WAR TIMES

By J. DONALD PRYOR[1] AND FRANK V. SACKETT,[1] PROVIDENCE, R. I.

Non-Members

IN its essentials the fire-protection problem in war times does not differ from the fire-protection problem in peace times. It is true that war conditions aggravate and increase ordinary fire dangers, but the means found most efficacious for combating them in normal times are still most efficacious.

A great deal has appeared in the daily press on incendiary fires set by German agents, and the colossal amount of our fire losses last year—totaling as it did some $250,000,000, an increase of more than 25 per cent over normal—encouraged the belief that enemy aliens were responsible for the greater part of our staggering contribution to the fire Moloch.

Unquestionably, enemy agents did cause heavy fire losses—perhaps $30,000,000, but according to the National Board of Fire Underwriters certainly not more than this. It only about 10 per cent of our fire losses since we have been in the war have been due to enemy aliens, surely our attention should be focused on some means of stopping the remaining 90 per cent of the losses in quite as great a degree as it is on checking enemy spies.

The stationing of sentries outside of munition-manufacturing plants and other war industries appeals to the imagination of the public. It looks like real preparedness against the machinations of enemy agents, and it is, but as U. S. Attorney General Thomas W. Gregory says: "Statistics show that the chief dangers menacing private manufacturing plants are those which originate or are developed within their own boundaries. The real protection needed is protection within the plant itself, and the prime responsibility for the internal protection of workshops and factories rests, as it always has rested before, upon owners and managers."

What is really at the bottom of the present public interest in our fire losses is that our country for the first time is awake to the real meaning of fire loss. Before we entered the war, fire losses were regarded as a passing misfortune to individual business men, which misfortune they passed on to the insurance companies. And the public, business men in particular, shrugged their shoulders at fire-protection engineers and went on believing that fire-insurance indemnity was a panacea for fire losses.

Now the country is awake to the fact that a fire loss is no longer a private matter but a national consideration. They realize that insurance money is but a poor substitute for destroyed supplies. For the first time they realize that thinking insurance indemnity is a cure for a fire loss is just as sensible as thinking that German submarines are impotent simply because the ships they sink are insured. Faced with the task of supplying in great measure all of the sinews of war for the Allied cause, we have come to see that food and guns and machinery and clothing are themselves the valuable consideration, and not the amount of money they are worth.

Last year's increase in the fire loss is readily accounted for when we realize the tremendous speeding up of industry, the employment of unskilled labor, night-and-day operation and crowded storage, all of which have been part and parcel of our participation in the world conflict. Compared to other countries these considerations are those which have always made the fire losses of America the most amazing piece of wastefulness the world has ever seen.

In no country in the world has fire-protection engineering in the way of appliances for fighting fire, either manually or automatically, reached so high a degree of perfection as here. Nowhere in the world has fire-resistive construction been developed to such an extent as here. But in spite of this our fire losses, even in peace times, are staggering. In part this is due to our tremendous values. In some measure it is due to our large-area buildings and high-speed production, and in great measure it is due to our carelessness.

But at the present time our values are mounting higher and higher. Production is being speeded as never before. Surely the answer to our problem cannot be found by correcting either of these elements in the situation, for we positively must increase supplies and further speed up production. There remains for us only one way in which to effect the cure for this red disease which is sucking our resources; and that is to be more careful that fires do not start and more careful that we have at hand the means for putting them out when they do start, as some of them inevitably will.

The usual business building, be it manufacturing plant, storage warehouse, dock, pier or shipyard, is roughly classified by the insurance companies as being protected or not protected. It is a curious commentary that at present the three most essential classes of property in our country are those least protected. They are in order of their importance as follows:

a Shipbuilding yards
b Flour mills and grain elevators
c Piers, wharves, docks and storage warehouses.

There are two other great classes of vital industry—metal-working establishments, including foundries and machine shops, and textile mills, in which we have placed cotton mills, full-process knitting mills and woolen mills.

The average munition works, being a metal-working risk, has not the severe hazard of the foregoing classes of risk, and yet the fire loss among the metal workers is in itself astounding, and that industry, while its largest units fall into the protected class, has many small units where values have not to date been sufficient to induce owners to fully protect such property. Our textile mills producing clothes for our soldiers are the best and most completely protected class of property in this country, and probably in the world.

Fire Protection of Metal-Working Establishments and Textile Mills

Before passing to a consideration of the fire-protection problem of the three unprotected classes of essential properties noted above, it may be well to outline briefly the fire-protection equipment of the two protected classes of property, namely,

[1] General Fire Extinguisher Company.

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

metal-working establishments and textile mills, and see what new demands the war has made on their fire-fighting facilities.

The increased hazard of fire in metal-working establishments has to do almost entirely with processes incident to their manufacturing ammunition, and a complete outline of the processes involved is almost essential to the thorough understanding of the new hazards involved. This whole matter was treated in detail at the 1917 meeting of the National Fire Protection Association, where a paper was presented by Mr. W. D. Milne, Inspector of the Underwriters' Bureau of New England. Except for one or two increased hazards in the treatment of steel, most of the new processes where serious hazards are involved are those having to do with the loading of the shells rather than with the making of the various parts, and those wishing to make a complete study of this matter are respectfully referred to Mr. Milne's paper, which will be found in the Proceedings of the National Fire Protection Association for 1917.

In conjunction with this paper on the manufacture of ammunition, Mr. Milne, in collaboration with Mr. N. Richardson, also presented some valuable suggestions on safeguarding industrial plants from labor troubles of various kinds.

As noted in an earlier paragraph, the ordinary fire hazards are still responsible for some 90 per cent of our fire loss, and consequently a consideration of the best type of protection against these hazards is of even greater importance than the consideration of means to overcome abnormal conditions due to the war.

Perhaps the quickest way to illustrate the comparative safety of most large metal-working plants from ordinary fire danger is to briefly review an investigation made a year ago in this class of property. That investigation showed that the average insurance rate paid by metal-working concerns, unprotected by automatic sprinklers, was \$1.47 per \$100, and that the average rate paid by these same concerns after having installed automatic sprinklers was 20 cents per \$100, a reduction of 86 per cent in their average rate.

It should be remembered, however, that the requirements made by the insurance companies for sprinkler protection, which is the main dependence of all of these concerns, include certain other protection devices such as chemical extinguishers, oftentimes hose and hose connections and the installation in some cases of fire doors, the closing up of vertical openings, and, in many cases, the installation either of open sprinklers or fire shutters to guard the plants from exposure fires.

Since the insurance rate is invariably the truest measure of fire danger, it is readily apparent that these metal-working plants which have automatic sprinklers and other auxiliary protection are about as safe from the ordinary fire as it is humanly possible to make them.

The only danger from ordinary fires in these protected plants is that the fire-fighting equipment, either through carelessness or maliciousness, may become impaired, and in 1917 there were several disastrous fires in completely protected properties due to water's being shut off the sprinkler system.

The same type of protection that is enjoyed by these metal workers has been carried to its ultimate development in the great textile mills of the country, which were the pioneers in installing automatic sprinklers, and which are today enjoying rates on the average of from 7 to 10 cents per \$100. They, just as the large metal-working establishments, are immune from ordinary fire dangers provided their fire-fighting equipments are kept in working condition.

As a further indication of how successful automatic-sprinkler protection has been in safeguarding metal-working risks and cotton mills, we refer to the sprinkler-fire records of the National Fire Protection Association. These records show that in 6412 fires in textile mills, 98 per cent were successfully handled by automatic sprinklers. Of the 128 fires which were classified there as unsatisfactory, 37 were due to the fact that the water was shut off the system and 57 to defective equipment or supplies and unsprinklered sections. These two causes, which obviously are not inherent in the standard sprinkler systems as installed by experts, can therefore account for about 73 per cent of the so-called failures in this great class of risk.

The same records show that in 1283 fires in metal-working risks, 95 per cent were successfully handled by the sprinkler equipment. Of the 59 fires which were classed as unsatisfactory by the insurance companies, 30 were due to the water's being shut off the system and 19 to defective equipments and unsprinklered sections, these two causes contributing 83 per cent of the unsatisfactory fires in this class of risk.

Keeping Sprinkler Systems Efficient

These records show that unfortunately the fire-fighting equipments of these risks are not always in operative condition, and naturally the cleverly directed incendiary would take care to see that the sprinkler equipment was shut off, or otherwise put out of order before applying the torch. This danger of enemy activities, and also the fact that more unskilled labor than ever before is being employed in both these classes of industry, makes it particularly worth while to consider in addition to sentries and watchmen some automatic means of safeguarding their fire-fighting equipment, which equipment, in the last analysis, is automatic sprinklers.

The sprinkler-fire tables of the National Fire Protection Association show that out of 19,000 sprinkler fires in all classes of risk there have been 851 specified by the insurance companies as unsatisfactory. Of these 851, over 25 per cent, or 230, occurred because the water was shut off the sprinkler system.

As far as keeping the sprinkler service in all classes of risk in operative condition is concerned, and particularly as regards keeping the service intact in these special classes of risk, the most absolute safeguard is what is known as sprinkler supervisory service. This service is installed and maintained by the American District Telegraph Company and, briefly, consists of having the vital elements in a sprinkler system equipped with electric alarm apparatus, which automatically transmits a code signal to the central office whenever anything out of the way happens to the sprinkler system, in addition to automatically transmitting an alarm to the control station in case of fire.

For instance, as regards the matter of water being shut off the system there would be a switch placed on all controlling valves of the system, and if any of these valves, either through malicious intent or carelessness, were closed, the A. D. T. office would at once receive a signal of such closing and would immediately send a runner to correct the difficulty, or at least to ascertain if the owners were aware of the fact that their fire protection was impaired. The same general type of device can be applied to other elements of the system, but the mere equipment of controlling valves by protecting apparatus is one of the essential precautions which war conditions impose upon manufacturers who have otherwise adequately safeguarded themselves against having their production stopped and thus seriously interfering with the country's war work.

Where supervisory service is not available, or for financial reasons will not be considered, the importance of this matter

as evinced by the figures above quoted warrants the stationing of a man at any controlling valve of a sprinkler system which is closed for any reason whatever, and the keeping of that man there until the valve can be again opened and the system restored to service. Theoretically, if this stationing of men were religiously carried out this problem of closed valves and consequent heavy losses in protected properties could be avoided; but, unfortunately, the human element is such that this plan can never be considered as the ultimate answer to the problem.

The other chief causes of so-called sprinkler failures are generally defective equipment or water supplies and unsprinklered sections, these causes contributing 279, or 32 per cent, of the 851 so-called sprinkler failures in all classes of risk. For the most part, defective equipments are those installed before the present standards of appliances and installation were reached, and engineers should take care to thoroughly investigate the equipment in plants in which they are interested to see that it is in every way up to standard.

The matter of unsprinklered sections has always been a bothersome one, and it is particularly so in metal-working risks, because to the layman there are a great many sections of such plants where it seems almost impossible for a fire to start and gain headway. But it should be remembered that no man can tell when and where a fire will start, and that as far as the ordinary sprinkler equipment is concerned, an unsprinklered section acts to all intents and purposes as a severe exposure hazard; and at this time, when metal production is so necessary, every safeguard should be taken to see that such production is not stopped.

While it is true that the larger metal-working establishments, including automobile factories, are completely safeguarded by automatic sprinklers, it still remains a fact that there are a host of smaller establishments in this industry which are not so protected. The products of these smaller factories are often used in the larger, and patriotism demands that they should be protected against fire. Just remember that since 1908 nearly sixty million dollars in unprotected metal-working risks have been destroyed by fire, and the necessity of further protecting the smaller units of this industry becomes obvious.

Safeguarding Shipyards Against Fire

The war has once more made the United States a great maritime nation. We are planning to build more ships in the next few years than any other nation in the world, probably in mercantile tonnage nearly as much as all the rest of the world combined. So great has been the haste to rush shipyards to completion that in a great majority of cases fire protection, which is not a production but a conservation factor, has been overlooked. This is perfectly natural, but it is also extremely dangerous, because we must look at the ship problem not in terms of the money involved, but in the terms of the men we must put on the western front. It is estimated that it takes five tons of shipping per year per man on the fighting front. The destruction, therefore, of a shipyard capable of turning out 200,000 tons of shipping is just the same as if the Kaiser's troops had captured practically a whole army corps.

In general, there are two great classes of shipyards: (*a*) shipyards like the Bethlehem plant at Squantum, where the building ways and the slips are completely enclosed, and (*b*) the smaller yards where the ways are built in pairs with a runway between, and where there is seldom a roof over the ways, and practically never enclosing side walls. In the first type of yard the fire-protection problem is in most respects similar to the equipment of any large metal-working establishment or combination wood- and metal-working risk.

The more common type of shipyard, especially on the Pacific Coast and on inland waters in the eastern part of the United States, consists of office, storehouse, carpenter shops, etc., and where steel ships are being constructed, machine shops. These buildings are immediately above the ways and are usually of light wooden construction, generally one story high with a peaked roof, and sometimes a concealed space. The driveways and yards leading down to the shipyards are often planked.

The shipways themselves are close to the water's edge and are arranged in pairs, each pair being separated by wooden platforms or piers. These platforms on the land side are nearly the ship's depth lower than the completed hull, and a wooden stairway leads to an overhead platform or runway between each pair of ways. The timbering of the ways sometimes supports a light roof to protect the workmen, but the sides are practically never enclosed.

Obviously, this type of yard is a very serious fire risk, for almost invariably there is a strong wind blowing on the water and a fire starting at one end of the yard might well wipe out the whole enterprise in short order. Obviously, also, no scheme of protection can be devised which will invariably and infallibly protect such a plant, as it is impossible to expect automatic sprinklers to protect adequately the open-sided roofs of the ways where there is a roof, and sprinklers cannot be installed advantageously in the timbered runways.

The plan which has met with the greatest favor in safeguarding shipyards of this type is to run a large water main the whole length of the yard between the shipways and the buildings. The buildings are then completely sprinklered and feed mains are run from the large main down each platform, between each pair of ways, and hydrants are installed with an ample supply of hose so that fire on a burning way or ship can be fought from both sides. Usually two hydrants on the platform are considered sufficient. An improvement on this plan would be to install a standpipe with hose connection, which could be operated from the overhead platform above the lower working pier. This would provide vantage ground for fighting fires in the holds of ships partially completed without the delay of dragging a hose line up the stairway.

In shipyards where wooden ships are being constructed, and where consequently there is an enormous amount of lumber stored, the risk approximates that of the ordinary lumber yard. Such lumber yards should, of course, have adequate protection in the shape either of a complete hydrant system, or, better still, a system of standpipe monitor nozzles.

Briefly, this system consists of a series of standpipes about 24 ft. high, each carrying a monitor nozzle and a platform at the top. The standpipes are spaced about 90 ft. apart, and such spacing allows the nozzles to absolutely command any fire in the protected area. A ladder leads from the ground to the platform so that one man can quickly get the nozzle into operation, and by reason of a set screw direct it on the fire and then proceed to set another nozzle into operation, thus effectually attacking the blaze from several standpoints.

The initial water supply to this system can, as a rule, be taken from the mains which feed either the sprinkler system or the shipway hydrant system, but in addition to this there should be a fire pump taking suction either from city water, a reservoir or any other large supply such as a pond or river. The pump is controlled by a switch on the platform of the standpipe, so that after the primary supply has been started

there may be no delay in providing the extra pressure which such sweeping outdoor fires require.

At the base of each standpipe there is a post indicator valve which the operator opens before he goes to the platform. In connection with this valve there is also a drain which should always be left open when the nozzle is not in use, so that there may be no water left in the standpipe. This insures against freezing, which is one of the serious faults of the usual hydrant system.

The thought naturally occurs that the yards building wooden ships would be much more hazardous than the yards building steel ships. But this is not always the case, because the constant dropping of red-hot rivets in steel ship construction on the wooden platforms causes many fires and the underwriters feel that the danger is practically equal to the danger in the yards building wooden ships.

Obviously the various types of system above outlined for protecting the ways are largely dependent upon human activity, and the importance of the shipbuilding program would seem to warrant the yards in having specially trained men to handle their fire-fighting apparatus. We are not informed as to how far any of the yards have gone in this respect, but certainly if the hydrants are to be used most efficiently, any shipyard manager is shortsighted indeed who does not immediately organize and train his own fire brigade and install some type of manual alarm so that the men can quickly be summoned in case of fire and be fully instructed as to their individual duties in controlling it.

The fire brigades organized in a great many of the factories insured under the mutual system or with the Factory Insurance Association are extremely efficient, and no better plan could be followed by the shipyards than to adopt these same measures, because a lot of untrained men with a long length of writhing hose will succeed in making themselves ridiculous about as often as they will succeed in making the fire so.

Fire Protection of Flour Mills and Grain Elevators

Next in importance to the active prosecution of our shipbuilding program is the protection and conservation of foodstuffs, particularly wheat. France and England are now on short wheat rations, and we ourselves have had to curtail our consumption seriously. But in spite of this tremendously grave situation, the National Board of Fire Underwriters declares that we burn up wheat in grain elevators and flour mills at the rate of about $10,000,000 annually, the total destruction of foodstuffs running to about $25,000,000 a year.

That this rate of burning can be very greatly cut down by adequate protective measures, the chief of which is automatic-sprinkler protection, is clearly evinced by a study of the sprinkler-fire records and by a comparison of the fire-insurance rates on such properties before and after protection.

The records of the National Fire Protection Association, covering 70 fires in flour and cereal mills protected by automatic sprinklers, show that in 54.3 per cent of the cases the fires were completely extinguished by the sprinklers and that in 37.2 per cent of the cases the fires were successfully held in check. Of the so-called unsatisfactory fires, making in all 8.5 per cent of the total, half were due to partial sprinkler installation or exposure fires, leaving only 3 fires out of the 70 where the type of construction was such as to handicap proper sprinkler performance, or where the hazard was too severe for the ordinary sprinkler system.

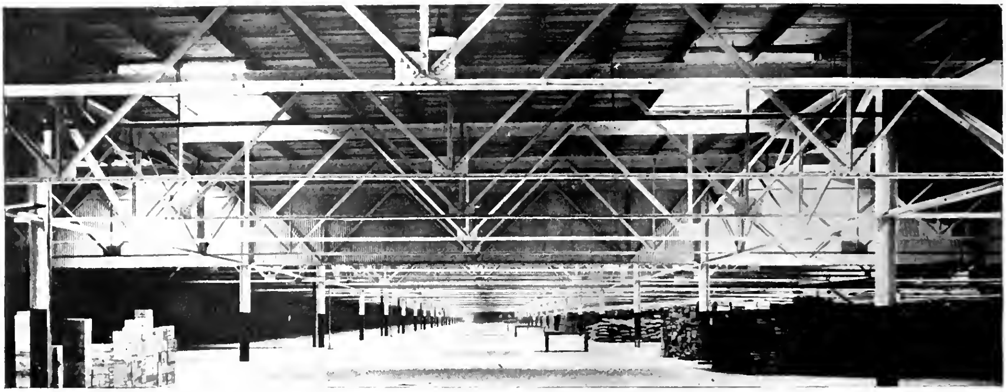

Fig. 4 A Sprinklered Pier in Brooklyn, N. Y. Note Curtain Boards Installed to Break up Ceiling Area and Bank Heat at Sprinkler Heads

The same records show for grain elevators a total of 52 fires, 38.5 per cent of which were completely extinguished by the sprinklers and 32.7 per cent successfully held in check. Out of the remaining so-called unsatisfactory fires there were only 6 where the hazard of occupancy or the nature of the building was such as to make unsatisfactory the performance of automatic sprinklers.

This record shows why the average insurance rate on flour mills and grain elevators before the installation of automatic sprinklers and other protective devices is $3.03 per $100 and why after such protection it is $1.01—a $66^2/_3$ per cent reduction. There is no doubt but that the hazards involved in this class of property are many and severe, not only as applied to the processes carried on, but on account of the general nature of the construction.

One of the greatest hazards in flour-mill operation is in the fast-running machines and in the processes of cleaning and reducing the grain. Nails and bits of wire are often drawn into the separator and cause sparks, resulting frequently in dust explosions. In this connection a report made many years ago is of interest. On May 2, 1878, the Washburn Flour Mills, Minneapolis, were wrecked by an explosion. A commission investigated and tested flour and coal dust. It was concluded

that "all finely divided carbonaceous material will explode."

The great number of elevators and conveyors running respectively vertically and horizontally through the plant make an enormous addition to the fire risk. The chances for fire to get a good start and to spread rapidly are so great that automatic sprinklers are placed somewhat differently from the method used in the ordinary factory building. The heads below the ceiling are spaced according to the usual standard, though frequently a little closer together. Around the elevators they are spaced as closely as they can be put without interfering with each other. They are also placed as near as possible to the elevator legs. The latter act in case of fire as veritable flues. To offset this an automatic sprinkler head is placed at the top of the elevator head inside the hood. The entire volume of water from this head would be discharged down the elevator leg and deluge any fire within it.

Freight and passenger elevators and stairways make another great hazard, and sprinklers are placed close to the elevator wells and under all stairways. Sprinklers are also placed at the top of the elevator shaft to protect the machinery, while the great number of nooks, crannies and other out-of-the-way places in such a building all have to be adequately protected.

The protection of the storage bins in the elevator section of the plant is a problem in itself. In cases where the bins are subdivided at the various floors, the same ceiling arrangement of sprinklers is adopted as in the mill building itself. In some installations, particularly where the storage is arranged in the form of silos, additional heads are placed beneath the floors of the silos, as well as in the space between the walls and the sides of the silos.

A considerable percentage of unsatisfactory sprinkler fires in this class of risk were made unsatisfactory by vertical openings or faulty construction. The maximum sprinkler efficiency cannot be expected where the automatic sprinklers are at a disadvantage with regard to distribution of water or rapid spread of fire, such as is produced by vertical openings, flimsy construction or concealed spaces sheathed in wood. All of these elements tend to spread a fire rapidly and should be avoided in every case possible.

An analysis of flour-mill fires during ten years, made by the Millers' National Insurance Company, showed that just half of the fires proved a total loss, while the other half gave a partial loss. Seventy-three per cent of all fires occurred at night, 58 per cent of which were total losses; 71 per cent of the total-loss night fires were from causes unknown.

In spite of the fact that sprinkler protection obviously minimizes the danger of fire in these properties, and in spite of the fact that insurance rates are so largely reduced for such installation, there are, comparatively speaking, but few of this class of risk under protection. The very large mills almost invariably have such protection, as do the elevators in connection with them. But up to the present time economic considerations have prevented carrying this protection into smaller mills, country elevators and terminal elevators on the wholesale basis that the hazard and irreplaceable values at stake demand.

A great number of these smaller mills are located in sections where there is no adequate city water supply, and the consequent expense of tanks in connection with the equipment has worked to keep these properties unprotected; for business men seem invariably to demand that as far as fire protection is concerned they must be shown a very large and attractive investment through insurance savings or else they will not install the equipment. Unbelievable as it seems, there are few men who consider adequate fire protection a thing which they themselves can afford to pay money for out of their own pockets. They insist that the insurance companies to all practical intents and purposes foot the bill. Even with the necessity for installing tanks, sprinkler equipments in a large number of these mills would show the owners 6, 8 or 10 per cent annually on their investment, but this is not sufficient reward to induce them to make their properties safe from fire and thus help to conserve our food supplies.

In the country grain elevators the same condition applies as regards water supplies, and in addition the grain stored in the elevators is in many cases not owned by the same parties who own the elevator. Moreover it is usually stored for a period of only three to five months. This combination of circumstances and the seeming inability of the owners of the grain and the owners of the elevator to get together on a coöperative basis has worked to create a financial barrier against the equipment of these properties with automatic sprinklers.

As regards the great terminal elevators, the question is not one of water supplies, as these are in most cases available.

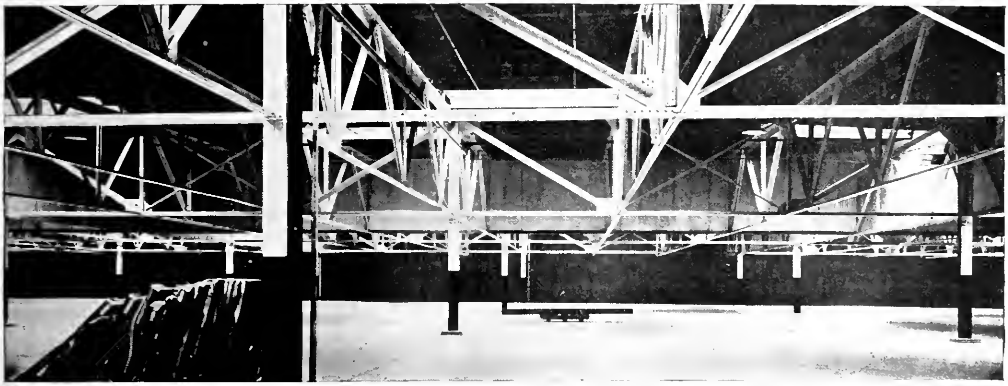

Fig. 2 Another View of Pier Shown in Fig. 1. Note Particularly the Curtain Boards Running Lengthwise of the Structure

FIG. 3 SPRINKLER LAYOUT FOR A TYPICAL PIER PROPERTY (SEE CONTINUATION IN FIG. 4). NOTE PARTICULARLY THE OPEN SPRINKLER EQUIPMENT TO GUARD AGAINST EXPOSURE FIRES

Even where they are not, the values at stake are so great that the savings by reason of sprinkler equipment would pay for the systems in a comparatively short time. The trouble here is an exaggerated case of the same thing that exists in the country elevators, namely, that the elevator owners and operators do not own all the grain being stored or in process. Since the great value at stake is in the grain itself, and since owners of the grain cannot see why they should spend their money to improve an elevator which they do not own, enormous quantities of irreplaceable food values are at the mercy of fire in one of the most hazardous classes of risk.

While the engineering problems involved are a little more difficult than ordinary, they have been satisfactorily solved, and the protection of these properties is held up for financial reasons rather than on account of the engineering considerations involved.

Seaport Problems

Let us suppose, however, that there are no catastrophes in our great shipyards and that the country is successful in producing the needed ocean carriers. Let us suppose that the great ten-million-dollar-a-year fire loss in flour mills and grain elevators is stopped and that the grain is cleaned and milled and ready for shipment abroad. Have we then escaped all of the fire dangers which threaten to seriously impair our active prosecution of that part of our war work which has to do with feeding our Allies and providing supplies for millions of men abroad, including not only food but munitions, clothing, guns, aeroplanes, automobiles, etc.?

By no means. One needs but to visit any great Atlantic seaport today to see almost unbelievable quantities of supplies congested in piers, wharves and storage warehouses for shipment abroad. Our seaports are literally packed with vital necessities for France. No better idea of the fire hazards incident to such seaport congestion can be given than to quote from a book written by Fire Chief John Kenlon of New York, who perhaps has had more experience in fighting waterfront fires than any other man in America. Here is what he says of fire-protection problems in American seaports:

> The sheds or wharves, common to America, form about the most dangerous structures of their kind in existence. Built on wooden piles, with wooden superstructures, they are comparable to nothing but horizontal flues, through which flames rush with a lightning rapidity, rendering abortive any efforts on the part of the fire department unless the greatest promptitude is shown by all concerned, and demanding the use of fireboats with specially designed and extraordinarily powerful equipment. Fill these sheds with every sort of combustible material imaginable; hogsheads of resin, bales of cotton, crated furniture, barrels of pitch, stacks of dry goods, and such unconsidered trifles as a few boxes of celluloid toys and novelties, and can the mind of man conceive a collection of heterogeneous merchandise more calculated to provide the wherewithal for a conflagration and matter enough to assuage the thirsty pens of all the newspaper reporters in the town? Yet this represents an every-day condition in an American port, and it is perforce necessary not only to guard this property but to calculate the even more important risk, namely, should fire occur, the danger of its spreading to adjacent dwellings.

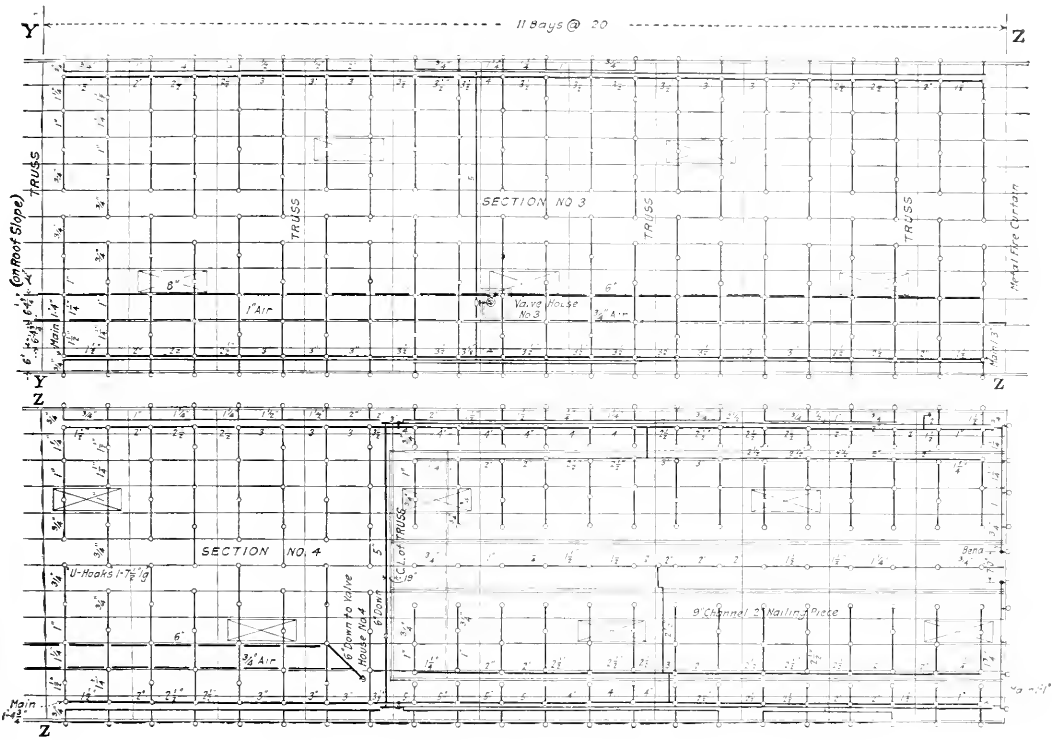

FIG. 4 SPRINKLER LAYOUT FOR A TYPICAL PIER PROPERTY—CONTINUATION OF FIG. 3

Fire Protection of Piers

The protection of pier properties involves special hazards which require special attention and constant following up, and on account of the extreme importance of this matter we outline briefly, in detail, the conditions found on piers.

Construction. Construction varies to a considerable extent, but in general the tendency of the past few years has been to improve the type of buildings used for this purpose. No doubt good construction would be of material assistance in safeguarding against the danger of fire, but, unfortunately, the present crisis will not permit of sufficient time to change existing construction defects. Frequently we find fire-resistive construction in the more modern properties, and a few sprinklered piers. Some are also found with fireproof floors and of slow-burning construction. In general, however, piers consist of one-story corrugated-iron buildings supported on wooden frames and wooden piles. Sometimes they are two-story buildings, but always with high ceilings and large openings in the sides for loading purposes. Almost invariably they connect by unprotected openings with adjoining bulkhead buildings of ordinary construction and considerable size.

Area. One of the worst features of piers is their large area, which is all open and subject to heavy drafts. Very seldom are these areas broken up by dividing walls, and unquestionably some good could be accomplished along these lines. For instance, fire breaks could be installed both above and below pier floors which would prevent the fire from spreading so rapidly and thus give the fire fighters a chance. Owing to the fact that piers are subject to heavy vibrations and movement, a great many could not be protected with standard fire walls, but fire breaks could help considerably and might be made of corrugated iron above the floor and heavy timbers below the floor, a construction which would not be affected by the movement of the pier.

Accessibility. From the very nature of piers they are less accessible than ordinary buildings. Their location near railroad terminals or on waterfronts means a frequent delay on account of congested traffic conditions. Furthermore, the ordinary building is accessible to fire fighters from all four sides, while piers are accessible only from one side, and that is always the short side. Approach from the water sides may be cut off by barges blocking the slips, and regulations should be made to keep these slips clear so that fire boats can approach from all sides.

Occupancy. The handling and storage of all sorts of supplies, from dangerous chemicals to aeroplanes, which must be received in whatever condition they are delivered by the transportation companies, is a dangerous operation. Furthermore, there is a constant change in the kind of material passing through from day to day, and this changing in itself produces a hazard, as elements that may be safe enough in themselves are frequently brought in contact with other elements which may cause them to be dangerous. Undoubtedly one of the worst features about this miscellaneous stock is the trouble with broken packages and containers, and the constant spilling of the various contents about the pier, where they may cause trouble later on.

Hazards. The lighting and heating hazards are about the

same as in the ordinary building, and apparently well taken care of, but, of course, they must be continually followed up.

Smoking. No matter what regulations there are regarding smoking, it is a hard matter to handle. The danger from this source is always present, and the only remedy is to keep after the matter and treat offenders severely.

Help. The scarcity of labor has resulted in the employment of undesirable and irresponsible help. It is a case of that or nothing, and certainly results in an increased hazard in handling. These men are not efficient, and are not trained in matters of fire protection as well as in ordinary times. There is no remedy for this condition except a careful and continual watching of these men.

Exposures. Piers are subject to exposure fires not only from adjoining frame structures on land and other piers but also from vessels alongside and floating material from other fires in the vicinity. They are much more susceptible to exposure fires than ordinary property, because the high winds prevailing on the waterfront carry flying brands greater distances and fan these incipient fires wherever they start. An excellent illustration of this feature was the Jarvis fire on the Jersey City waterfront, which spread across the river to a pier in New York. The vessels alongside and in the harbor are also hazards, because the employees on board are careless about fire-protection matters and are not under restraint by the pier owners. Frequently boats containing dangerous contents catch on fire and they may expose several piers in the same harbor.

Fire Protection. Too much emphasis cannot be placed upon the necessity and importance of ample water supply for fighting pier fires, and yet during this last winter a large section of the Jersey City waterfront was greatly endangered by low pressure in the city mains. Reliable reports indicate that at the time of the coal shortage and very cold weather the city pressure at many points near pier property was *under 10 lb.*

This danger was somewhat offset by good private supplies, but it simply indicates how bad things can get when not properly followed up. The size, location and condition of all mains and outside fire hydrants are matters that must have continual attention, or they are liable to fail during an emergency. Instances of this kind have already occurred.

Inside Standpipe and Hose. For instant use with incipient fires and to hold them until the fire department arrives, proper standpipe and hose connections are essential and are generally provided. It appears, however, that this form of protection is open to some objections not common in other property, namely:

a Subject to freezing, as shown by many cases that happened last winter

b Liable to be used by crews of boats alongside for purposes other than fire and damaged or left out of condition by them

c Frequently inaccessible or blocked by piling of goods too near hose racks

d Control valves are necessarily located out of reach, and when the operator finds the fire too severe he is liable to run without stopping to close the valve, allowing the waste of water when most needed

e Condition of piping where salt water is used frequently requires special attention on account of barnacles, pitting, etc. The only remedy for these conditions is constant inspection and frequent tests of the apparatus.

Extinguisher Pails and Casks. The value of this form of protection lies in the fact that every one knows how to use pails and casks, and if used in time they may save loss. They must be looked after frequently to see that they are ready for instant use.

Watchmen. This is one form of protection that means much or little, depending entirely upon the watchman himself. In the past the main trouble has been that men used for such purposes were not competent to fill the position, frequently being pensioners and others who were not physically fit. The importance of having strong, alert young men is becoming more apparent. When it is remembered that every night the entire protection of great value is solely dependent upon their good judgment and faithful efforts in a monotonous job, it will be understood that first-class men must be employed. It is also advisable to have a watchmen's checking system, and they must be thoroughly instructed in the detection and fighting of fire.

Fire Alarms. Both city and local fire alarms are desirable. The important thing is to give the alarm promptly upon the discovery of the fire, as assistance cannot be rendered too soon. For some reason or other there seems to be more trouble with delayed alarms in connection with pier fires than with other classes of property, and too much importance cannot be laid upon the necessity of early alarms for pier fires. Local fire gongs operated from the same box are desirable for the purpose of notifying all employees immediately, and furnish the best method of drilling them.

Fire Brigade. A well-trained fire brigade is a very great advantage because these men are constantly on hand and available. Their jobs depend upon getting the fire out. Further, on account of their familiarity with the property and the fire-fighting apparatus they are able to get at the trouble very quickly. They should be under the direction of some experienced head and drilled regularly in their duties. They should know all about the apparatus and what to do in any emergency. They should be men selected carefully for their qualifications along this line. Surprise tests should be made by the owners frequently to see whether they are properly responding to alarms.

Automatic Sprinklers. The value of these systems is well known, and where properly maintained there is no question as to their efficiency. Pier conditions require special consideration, as follows:

a They must be dry systems because the piers are not heated

b High ceilings and particularly draft conditions make necessary curtain boards to bank the heat at sprinkler heads for high efficiency

c Extra heavy water supplies are required because of the large area subject to one fire

d Outside sprinklers are sometimes necessary to protect from exposure fires on vessels, etc., that may be alongside of the pier

e Sprinkler supervisory service for the purpose of automatically calling in the fire department whenever a fire starts

f Proper housing for mains and dry valves to prevent freezing during cold weather.

Considering the serious hazards in pier property, it is a surprising fact that only a comparatively few piers have been protected with automatic sprinklers. For example, out of some 150 piers in Manhattan we find only one or two with standard sprinkler equipments. Brooklyn makes a better showing with 18 sprinkler equipments, and New Jersey with about a half dozen. In the entire country there are only about sixty piers safeguarded with sprinklers.

We find that it is practically the unanimous opinion of all the fire-protection engineers that sprinkler systems afford the best possible protection for this class of property, and many

of them believe it to be the only satisfactory form for their particular conditions.

Mr. E. P. Boone, of the New York Fire Insurance Exchange, has had more experience with sprinklered piers than any one else in the country, and he is an enthusiastic believer in sprinkler systems for piers. His experience covers a number of actual fires which have resulted in only nominal loss to the property on account of the quick action of the sprinklers. He has mentioned one case where fire opened some twelve sprinkler heads which extinguished the fire so promptly that there was no interruption to business. Although the smoke was thick, the drivers continued to operate their motor trucks, loading and unloading as though nothing had happened. Figs. 1 and 2 give a good idea of the way Mr. Boone adapts sprinkler protection to the special conditions existing on a pier. Large open areas are broken into sections by special curtain boards coming down from the ceiling which bank the heat at the sprinkler head in spite of the drafty conditions. Note that some curtain boards are parallel with the pier, and others intersect them at right angles, running across the pier together, forming large pockets for the heat to rise in. This construction is rather unusual, and is made necessary on account of the extreme width of the pier. Fig. 1 also indicates the great length of the pier. These views show one of a group of sprinklered piers owned by the Bush Terminal Company, whose property was recently taken over by the Government. Figs. 3 and 4 show the sprinkler layout for a typical pier property, and Fig. 5 a section through pier indicating provision for a metal fire curtain.

Conclusions

Everybody's business is nobody's business, and we firmly believe that serious trouble will result unless the entire matter is handled in a businesslike manner by some high authority with broad experience in this line. We submit:

a That there should be no question as to the reliability of all water supplies involved, either public or private

b That lighters and boats exposing piers should be compelled to conform to established fire-protection practice and not be permitted to endanger this property by using kerosene lamps, cooking stoves, etc.

c That dangerous chemicals, oils and highly in 'ammable materials should be segregated and kept separate from other supplies

d That barges and boats should not be permitted to block up slips, preventing access to the sides of piers

e That extra large areas should be divided by section walls or fire breaks

f That explosives, or explosive materials, should not be permitted near the important terminals

g That bulkhead buildings should be cut off from piers where-ever possible

h That sprinkler protection should be provided where conditions appear most serious

i That good, reliable watchmen should be employed at night to properly safeguard the contents

j That all dirt, waste and rubbish should be immediately removed and the premises kept scrupulously clean

k That, wherever lacking, all necessary fire-fighting apparatus should be provided and constantly tested and inspected

l That there should be a uniform practice established for handling all these matters, and particularly seeing that they are followed up from day to day.

In our opinion the desired results can be accomplished only in one way: The Government must create a special central authority, with necessary experts to make a complete study of the entire situation in all our seaports, and then place the responsibility of handling and following up such matters in this one central authority. It must be more than an advisory body, and should be composed of men with practical experience in such matters, and capable of enforcing the necessary regulations. This step is not only justified as a matter of business expediency, but is in reality a matter of military necessity.

We have sought in the foregoing to outline some of the broader principles of fire protection in essential industries, but in the last analysis each individual risk has its own particular problems which must be solved for the individual plant by the engineers in charge.

One thing that applies to all plants, all offices and all houses is the matter of cleanliness and carefulness. What this country needs is more careful national housekeeping, and in this connection the writer asked the Fire and Accident Prevention Committee of the National Fire Protection Association for a

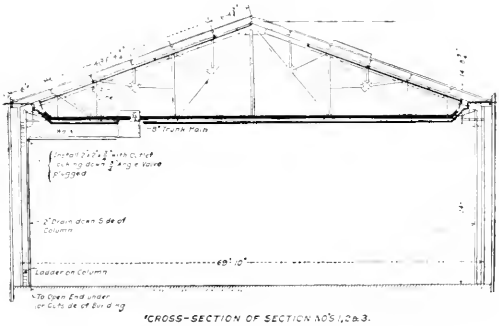

Fig. 5 Section through Pier of Figs. 3 and 4 Showing Provision for Metal Fire Curtain

brief outline of the work it is doing this year in trying to reduce the fire losses which are so serious a drain on our national resources. In reply they said:

"We plan to incorporate where possible, ordinances giving the fire department power to enter premises for clean-up purposes and to correct various undesirable features. We are at present formulating a program to include the education of school pupils in the details of fire prevention in the home, and to bring to the public a realization of personal responsibility for fires originating on their premises, whether homes or business.

"We are also arranging for parades and demonstrations and suitable literature through committees which are to be formed in various cities throughout the country. As to your paper before the Mechanical Engineers, that is an opportunity for you to place before them the great necessity for incorporating fire-protection features in their plans when they are called upon to outline any project. We must rely upon the engineers of the country to help us in the broader field, and where plants are being erected usually the first consideration should be the preservation of that property from fire. Their realization of this need will be a great help, not only in reducing the fire waste of the country but in preserving the necessary output of materials in this time of war."

OIL FUEL IN NEW ENGLAND POWER PLANTS

By HENRY W. BALLOU,[1] PROVIDENCE, R. I.

Non-Member

In the New England states there has of late been a rapid increase in the use of oil fuel in power plants, and in a convention partly devoted to the fuel problem a brief statement of the present status thereof may be of interest.

From data privately gathered it appears that oil fuel is now used in at least 60 different power plants in New England, having a total of 83,000 boiler hp. These installations are located as roughly indicated on the outline map of New England shown in Fig. 1. They are grouped according to states as shown in Table 1, from which it may be seen that two-thirds of the power plants and over one-half of the boiler horsepower so served are in Rhode Island.

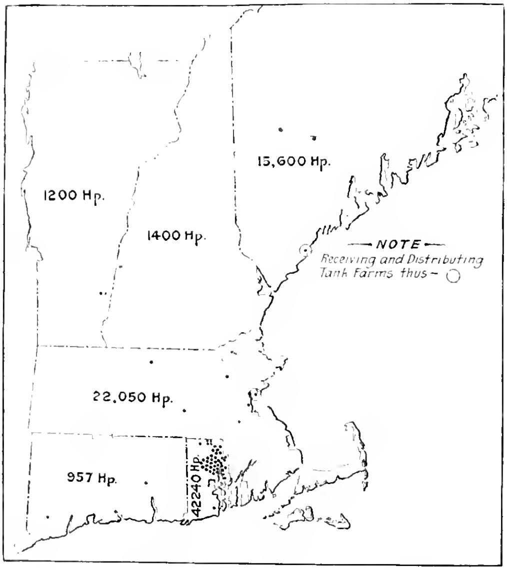

Fig. 1 Distribution of Oil Fuel Power Plants in New England, April, 1918

As shown in Table 2, most of these installations have been made in the past three years. When classified as to type of boiler, the result is as given in Table 3. When classified as to make of oil burner in use, the data are as presented in Table 4. It is estimated that in the year 1917 about 95 per cent of all of the fuel oil burned in New England power plants was used through Hammell burners.

Oil fuel is supplied almost entirely by the Mexican Petroleum Company from three tank farms located at Providence, R. I., Chelsea, Mass., and Portland, Me., having capacities of 257,000 bbl., 165,000 bbl., and 202,000 bbl., respectively. It is said that tanks have been ordered to increase the capacity of the Providence tank farm to 735,000 bbl., which is roughly equivalent to 200,000 tons of coal.

All of this oil is brought from Tampico, Mexico, a distance of over 2000 miles, in tank ships. The size of these tankers has greatly increased of late, the largest running into Providence being nearly 500 ft. long and drawing nearly 30 ft. of

TABLE 1 NUMBER OF OIL-FUEL POWER PLANTS IN EACH NEW ENGLAND STATE IN APRIL 1918

State	Number of plants.	Total horsepower
Maine	3	15,600
New Hampshire	1	1,400
Vermont	2	1,200
Massachusetts	10	22,050
Rhode Island	42	42,240
Connecticut	2	957
Total	60	83,447

TABLE 2 OIL-FUEL POWER PLANTS INSTALLED IN NEW ENGLAND, 1915–1918

Year	Number of boilers	Boiler horsepower
1915	74	24,450
1916	79	14,315
1917	98	22,382
1918	93	22,300

TABLE 3 BOILERS INSTALLED IN NEW ENGLAND OIL-FUEL POWER PLANTS, 1915–1918

Number of boilers	Make of boiler	Total boiler horsepower
130	Horizontal return tubular	22,582
88	Manning	16,525
81	Babcock & Wilcox	31,025
15	Heine	4,400
15	Stirling	3,800
5	Scotch marine	715
4	Gunboat	2,400

[1] Jenks and Ballou

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

water. Its capacity is 80,000 bbl., which is roughly equivalent to 20,000 tons of coal.

Local delivery from tank farms to power plants is by tank cars and auto trucks. Perhaps one-half of all fuel oil is delivered by auto trucks having capacities of from 1500 to 2280 gal. Such trucks, carrying 8 tons of oil, or enough to yield 2000 hp. for a 10-hr. day, will discharge their load by gravity in from 3 to 5 min. Oil trucks from the tank farms at tidewater in Providence make the round trip to the Tamarack power house in Pawtucket (a distance of 10 miles) in $1\frac{1}{2}$ hr., including both loading and unloading.

The oil is usually delivered at a temperature of from 80 to 85 deg. fahr. The quantity delivered is seldom checked by weighing or by temperature observations, the "delivery slip" of the oil company usually being accepted as evidence of quantity, after observation by the purchaser's agents that the truck is full on arrival and is allowed to thoroughly drain. Analysis or other test of the oil is seldom attempted by the purchaser.

The chemical constitution and freedom from impurity of the oil appear to be remarkably uniform, especially when considered in contrast with coal. Uniformity is presumably favored by marine shipment in bulk. So far as known, there is no accumulation of water or silt in the receiving tanks at power plants. The small quantity of water in the oil, frequently about one-half of one per cent, is said to be present as a sort of emulsion.

The typical New England power-plant equipment is often about as shown in Fig. 2. Cylindrical steel tanks, of capacity to serve from a day to several weeks, are usually set in the ground or in concrete vaults. Concrete storage tanks are also extensively used. A steam coil keeps the oil in the tank at a temperature of from 90 to 120 deg. fahr., whence it passes through an ordinary duplex pump and thence to the boilers at a pressure of from 18 to 30 lb., being heated to perhaps 180 deg. fahr. by the exhaust steam from the pump. A return oil pipe discharges into the tank, thus providing warm oil at starting and discharge for the relief valve. Oil pressure is maintained by a pump governor, and meters on both supply and return pipes register quantities. Strainers, pressure gages, thermometers and twin pumps are customary. The simplicity of the typical oil equipment when compared with that for coal is, of course, one cause of the popularity of oil fuel.

Insurance requirements appear to have ceased to be burdensome as standards of fuel and equipment have been found to be uniform and reliable. At present the two main requirements appear to be that the tank shall be below ground outside of the building walls and below the level of the pumps and boiler-room floor. Even these requirements have been modified in some cases. No difficulty is experienced in pumping oil as warm as 130 deg. fahr. with a 10-ft. suction lift; and one installation with a 15-ft. suction lift is said to be successful.

A statement of the causes and conditions which have led to this sudden adoption of oil fuel in New England may be of interest. Of course, a primal cause was active propaganda by oil and equipment companies; and the basic cause was the superiority of oil to coal. The merits of oil fuel, however, although long recognized in other parts of this country, are somewhat of a surprise to the manufacturers of New England.

About nine-tenths of these oil-fuel installations are a substitution for coal in existing plants rather than primal installations in new plants, and it is believed that fully nine-tenths of them have been made without the advice of a consulting engineer. This statement may seem more significant than is really the case, both because in a number of instances where a consulting engineer's opinion has been sought the change to oil has not been made, and because of the excellent grade of engineering skill employed by the equipment companies in solicitation.

In general, the owner has been convinced by the remarkable contrasts between coal and oil, and the simplicity and freedom from labor troubles, ashes and dirt have appealed to him most strongly. In a number of cases additions to power plants have been avoided by the use of oil fuel, and such a feature is one to conjure with in New England.

There is no other method of increasing the capacity of a boiler plant so quickly and so cheaply as by substituting oil for coal fuel. Defective-draft troubles disappear coincidentally and the lone fireman dozes peacefully in ten-minute naps. In a number of cases the change to oil fuel has made it possible to shut down one or more boilers. The resulting saving

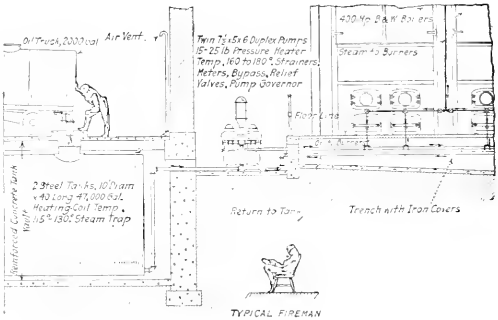

FIG. 2 DIAGRAM OF OIL-FUEL EQUIPMENT TYPICAL IN NEW ENGLAND POWER PLANTS

in radiation losses and maintenance is a typical illustration of the collateral economies of oil fuel.

In the judgment of managers, the minor nature of alterations in a boiler necessary to use oil fuel and the possibility of readily changing back to coal are vital features.

A few plants in New England have accomplished the automatic governing of the flow of oil and of the atomizing steam. Hand control of operation is almost universal, and is now attaining a standard of excess-air proportions never reached even in the highest grade of coal plants, some tests having shown as little as 20 per cent excess air. It is inspiring to contemplate the probability that automatic regulation of the oil, the atomizing steam and the draft pressure will all become a standard reality within a few years. Then will be the golden age of regulated combustion in New England power plants.

The advantages of oil fuel are ably set forth in the TRANSACTIONS for the year 1911 in a paper by B. R. T. Collins,[1] in which there are formulated seventeen well-defined ways in which oil fuel is superior to coal. Papers by C. R. Weymouth[2] in 1908 and 1912 are also noteworthy, and the U. S. Navy tests of 1905 and of 1916 are excellent evidence, if proof were needed, that, per heat unit contained, oil fuel is from 10 to 20 per cent more efficient than coal.

In an excellent paper on fuel oil, read before the Boston Section of the A.S.M.E. in 1917, Mr. F. W. Ewing estimated

[1] Trans.Am.Soc.M.E., vol. 33, p. 83.

[2] Trans.Am.Soc.M.E., vol. 30, pp. 775 and 797; and vol. 34, p. 639.

that parity in the price of coal and oil is reached when 26 per cent more is paid per heat unit of oil than of coal. This would be equivalent to about a 60 per cent higher price per pound of oil. While noting that this generalization should not be taken too seriously, the writer is inclined to believe that the many collateral economies involved in the use of oil fuel cause it to be true that in numerous cases even more than 60 per cent extra can be paid for oil.

The saving of labor due to oil fuel as compared with coal, while in itself large, has often been given a greatly exaggerated importance. Of the operating expenses in a New England boiler plant other than fixed charges, 80 to 90 per cent are usually for fuel. Accordingly a slight variation in the cost per pound of fuel may amount to as much as the total cost of labor. It has been said that a variation of a tenth of a cent a gallon in the price of oil will offset all saving in wages due to oil fuel.

It is obvious to engineers that, assuming a dependable supply of oil fuel at a price per heat unit equal to that for coal, the latter would soon cease to be used in the power plants of New England. The choice between oil and coal is therefore a matter of supply and not of quality. The only way in which coal may rival oil fuel is in price. It accordingly becomes of interest to consider what the future may have in store for the power plants of this section.

A recent review of the coal supplies of the world by the National City Bank of New York sets forth the remarkable fact that the coal deposits of the United States exceed those of the rest of the world combined and are seven times as great as those of all Europe. Of these prodigious deposits a large part of the finest steam coals lie in the states of Pennsylvania and West Virginia, within 500 miles of New England.

As to production, in the year 1917 the United States mined within 10 per cent of as much coal as the rest of the world combined, over one-half of which came from Pennsylvania and West Virginia.

The greatest supply of coal in the world being within 500 miles of New England, what, now, is the case for fuel oil?

It is notable that the question of supply is not simply about *oil*, but about *fuel oil*, which latter has been defined as oil which is more valuable as fuel than in the form of refined products.

It appears that crude petroleum may be divided into two classes, namely, one with a paraffin base and the other with an asphalt base. That with the paraffin base is so valuable for its derivatives—gasoline, kerosene, lubricating oils, and a thousand others—that its price will always be prohibitive for fuel. Moreover, rapid improvement in methods of distillation has made the refined products from the lighter asphalt-base oils so valuable that many of these oils have disappeared from the fuel market. Much that was fuel oil ten years ago is no longer fuel oil. Thus it is that of the four great oil companies, each having extensive tank farms at Providence tidewater, namely, the Standard Oil Company, The Gulf Refining Company, The Texas Company, and the Mexican Petroleum Company, only the latter is furnishing fuel oil for power plants. Indeed, at the present writing the Mexican Petroleum Company is unable to take any more contracts for fuel oil, and on the face of things it appears that oil is even now more scarce than coal. The question is not as to the world-wide supply of crude petroleum, but merely as to that small part of the whole supply which may not be readily distilled.

The extremely heavy grades of asphalt-base oils from Mexico are practically the only fuel oils now available to New England. It will be shown later that this Mexican supply (amounting to 55,000,000 bbl. in 1917), though in itself of great volume, is destined to cut but a small figure in the world's supply of fuel. Consequently, Mexican fuel oil will naturally gravitate toward those uses for which it will command a premium.

The question then arises as to what uses will pay a premium for fuel oil, and the answer is, those uses in which its superiority to coal are most important. The greatest of these is marine use. Consider the item of labor alone. It is generally conceded that in a large boiler plant the boiler-room labor with fuel oil may be only one-tenth of that with coal. On shipboard the labor of coal passing and trimming bunkers greatly exceeds similar labor on land. When, as on shipboard, it becomes necessary not only to transport the heavier and more bulky coal but also to transport the laborer, his housing and keep, it is unquestionable that fuel oil will command a premium for marine use as compared with its use on land. The seventeen superiorities of oil fuel formulated by Mr. Collins apply with greater force on shipboard than on land. And the same statement is true in a slightly less measure in the case of locomotives as compared with stationary power plants.

The coal review of the National City Bank estimates the marine use of coal at 75,000,000 tons per year, or five times as much as the entire output of the Mexican oil fields. The Pennsylvania Railroad alone would take a large part of the total oil output of Mexico. Moreover, the relative ease of marine transportation of fuel oil will cause it to displace coal in places that are remote from coal deposits and difficult of access. Already, in 1917, over 3,000,000 barrels of this fuel oil went to the west coast of South America.

While prophecy is ever hazardous, it is probable that in the long run the use of fuel oil in New England will be confined to those special uses and sporadic cases which, for one abnormal cause or another, can afford to pay the premium that oil fuel will command for uses outside of power plants. Oil fuel will within a very few years become a luxury for power plants.

The kinds of power plants which may be warranted in paying the premium that oil will ultimately command for transportation uses might include those plants which must maintain banked fires for considerable periods, such as plants auxiliary to water power or boilers serving fire pumps.

The premium may also be paid by small, prosperous plants in cities where smoke, dust and dirt are especially objectionable, coal storage difficult, ashes disposal expensive, and the labor expense and managerial oversight disproportionately burdensome.

In a word, oil fuel is incomparably superior to coal; but that very superiority, together with its relative scarcity, will ultimately debar it from New England power plants.

Just at present the user of oil fuel is enjoying those benefits incidental to extreme labor scarcity and abnormal prices for coal, and the lucky few who happened to have long-time contracts are reaping a golden harvest; but these conditions are ephemeral. Doubtless the whole cost of many oil-burning installations will be saved well within a period of five years.

The present rapid increase in the use of fuel oil in New England power plants is but a lucky incident in the marketing of a great natural product. Immense as is its absolute volume, the insignificance of its relative volume as a source of world-wide fuel has thus far been the main obstacle to the adoption of Mexican oil on the high seas. That obstacle is rapidly disappearing, and, regrettable though it be, it is inevitable that its very virtues will ultimately deprive the power plants of New England of fuel oil.

THE WORKMAN'S HOME: ITS INFLUENCE UPON PRODUCTION IN THE FACTORY AND LABOR TURNOVER

BY LESLIE H. ALLEN,[1] BOSTON, MASS.

Non-Member

THE events of the past twelve months have shown up in no uncertain way many serious defects in the structure of our social system. So many things in which we prided ourselves and rested with confidence have fallen apart or shown essential weaknesses. The earnest efforts of all who have at heart the welfare of our country and its people are needed to redesign and reconstruct the defective parts of our social machinery in order that we may maintain the leadership of democratic nations that we now hold and enjoy.

Among the industrial and economic problems which have disclosed themselves and are pressing for an immediate solution is that of the housing of the working classes, the subject of this paper.

Let it be recognized at the outset that this problem is entirely distinct from that of the housing of the poor, a problem of equal urgency and of greater difficulty, a problem in which we all are, or ought to be, equally interested. In addressing The American Society of Mechanical Engineers in their professional capacity, I have, however, restricted myself to the subject of housing the working classes, a subject that bears an important relation to the professional work of the engineer rather than to his social sympathies.

The high wages that now prevail are not bringing to the workingman either wealth or comfort. The shorter hours that the unions have devoted so much time and effort to secure and have often fought for with so much bitterness have not produced any corresponding improvement in the workman's condition. This is largely because the workman is unable to secure a comfortable home in which to spend and enjoy his hours of leisure. If he earns high wages rents are raised by landlords generally and prices of other commodities go up in like manner, and in growing centers of industry houses are usually impossible to obtain. At the present time, when the cost of building is so high, new houses are not being built to accommodate the growth of population or its concentration in industrial centers engaged in munition work and shipbuilding, and the result is an altogether disgraceful amount of overcrowding. It is becoming the rule rather than the exception for two or even three shifts of men to occupy the same beds in overcrowded rooms, and it is practically impossible for any workman, skilled or unskilled, coming to a new town to bring his family with him; he has to come alone and crowd in as a lodger with others.

None of us have attended this meeting to discuss matters of abstract interest, and in addressing the members of the Society it is most important that the connection between the housing problem and their professional work be clearly established.

Lack of Housing a Frequent Cause of Labor Turnover

Recent investigations have shown that one of the most important causes of the present abnormal labor turnover is the lack of sufficient homes to house the population around industrial plants and the altogether unsatisfactory nature of such houses as there are.

It is hardly necessary in this paper to present figures regarding labor turnover to a meeting of engineers; it is a pressing problem that you all know more about than the speaker. Ten years ago we should have felt rather ashamed of a turnover of 100 per cent per annum. Many large plants now consider themselves very fortunate if they can get below 200 per cent. Those who do not keep track of their figures may be inclined to dispute this, but those who through their employment department keep records of their labor turnover will unanimously bear out the general statement made above.

The fact is, that in spite of high wages the living conditions in our manufacturing centers are so miserable that a workman cannot endure a long stay in one place, and he soon throws up his job and moves on to the next town for the sake of a change in the vain hope that he will find something better than the conditions he has just left. Such men separated from their families and roaming from place to place soon degenerate into the "floater" class that is such a big problem to our employment departments.

Results of a Questionnaire on Means of Reducing Labor Turnover

In order to bring out more clearly the importance of good and adequate housing as a means of reducing labor turnover, the Aberthaw Company has just prepared and circulated a questionnaire among employers of labor, asking for figures on their labor turnover and on the character and sufficiency of the house accommodations around their plants. Prior to this, as far as could be ascertained, no data had been assembled on this relation, although the opinion has been widely held that housing has an important influence on labor.

Eight hundred and forty replies were received, containing a mass of most interesting information. The replies were from typical plants in the eastern and middle-western states, some in cities and some in small towns, and may be taken as a fair average statement of conditions.

As we expected, only a small proportion ($18\frac{1}{2}$ per cent) of our correspondents kept any record of their "hiring and firing"; of those who had kept records on turnover nearly a third had started keeping their records within a year.

Very few of those answering stated that they housed all their help, but 17 per cent owned some houses.

In answer to our request for an expression of opinion as to the influence of good housing, nearly all replied that it was a benefit to a manufacturing plant, tended to hold the men and made them more contented and happier, but there was some division of opinion as to whether it reduced time lost through sickness.

The opinion is held by all manufacturers located in large cities, such as New York, Philadelphia and Buffalo, that in very large communities housing has no bearing upon labor supply—with the exception of one firm in Detroit, which attributes a large reduction in turnover to selecting its new employees from those who live within half a mile of the plant. No firm in a very large city shows any interest in housing, al-

[1] Aberthaw Construction Company.

For presentation at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

though in many cases the turnover is just as large. Whether this opinion is a correct one due to there being an excess of supply over demand for houses or for labor or both, in our big cities, or whether the opinion is fallacious, we are unable to say.

TABLE 1 RELATION BETWEEN LABOR TURNOVER AND HOUSING

Turnover	Percentage of localities reporting adequate housing	Percentage of localities reporting insufficient housing
Less than 50 per cent	52.5	34
50 to 100 per cent	21	35
100 to 200 per cent	14	14
200 to 300 per cent	7	6
300 to 400 per cent	3.5	8
Over 400 per cent	2	3

Table 1 has been compiled from the answers received. It indicates that over 50 per cent of plants reporting turnover which have adequate housing around them have a turnover below 50 per cent, while only one-third of the plants where housing is insufficient report as low a turnover as this.

Combining all plants reporting a turnover of less than 100 per cent, the figures are only slightly in favor of those which have adequate housing; above this point the advantage rests with the well-housed plants.

Extracts from Replies to Questionnaire

The figures obtained cannot be called conclusive, and it is probable that many with records of high labor turnover did not care to disclose them. Of far greater interest and value are the replies returned with the questionnaire. Some of the more interesting follow:

A Pennsylvania mill has some very positive evidence of the cash value of good housing. Their manager writes us:

Our two blast furnaces are located about twenty miles apart, and between them is the blast furnace of a rival company. We consider our housing facilities superior to theirs, and to give you an idea of the effect of this would state that for years past they have had to pay more per day, of the same number of hours, for all of the men they employ around their plant. Of course the wages differ for different positions, but any position at their plant pays more money than a corresponding position at either of our two plants.

Furthermore the general living conditions around one of our own plants are somewhat better than the other, and in view of this we find we have to pay a differential in the labor scale although the plants are only twenty miles apart.

Hardly a month goes by that we do not get some men to come to us from this rival furnace, stating that the reason for moving is, though they get less wages, the housing conditions are better around our plants.

I might say that while we have not got the exact figures for comparison, we believe our labor turnover is exceptionally low compared to other plants in the same line of business, and we find the difference between the labor turnover at our different plants bears a relation to the desirability of the houses and living conditions at the respective plants.

A New Mexico mining company that has laid out one of the most charming and artistic villages owned by a copper mine, writes us:

When this camp was new, it was composed mainly of single men, the number of married men gradually increasing with the age of the camp until now a large majority of the men are married. This has necessitated the building of additional houses from year to year to take care of the demand, although there has been no material increase in the number of employees.

Without a doubt, a married man settled down in a house with his family is much more contented than a single man who is living in a boarding house. It is a fact that a married man will not jump up and leave his work on the slightest provocation, whereas a single man without a family connection frequently gets up and leaves without notice, for no reason whatever.

During the war period miners' wages are increasing rapidly, and in the very recent past there has been a great shortage of men. With the increase in wages and the shortage in labor, men have a tendency to want to move around from place to place to see if they cannot find something better. We have had a great many cases of men coming for the fourth or fifth time and giving us a list of fifteen or twenty places where they have worked in the past four or five months. During normal times we can safely say that an employee is more contented, happier and attentive to business when comfortably domiciled.

Indianapolis is a city we should all like to live in. Each manufacturer who writes from Indianapolis speaks of it as a city of homes. For instance, one letter says:

Indianapolis is a town where a great many workmen own their own homes. It is possible for a man to buy a piece of property in a decent part of the town with a good house on same by making a small cash payment and making the balance of his payments at about what he would pay for rent. We believe that this is a very good thing for the city, and for the industries and the men located therein. It has a tendency to stop the shifting and constant changing of men, and is of an economical value because it promotes saving and altogether produces a better grade of workmen and citizens.

It is our belief that there is not the great shifting among the workmen of Indianapolis that you will find in other manufacturing cities. At the present time we do not doubt but what the population is shifting more than under normal conditions, but we do not believe that this percentage of change is as large with us as it is in other communities.

A small Connecticut town of home owners seems well content, as one reply says:

A great many of our employees own their own homes, a factor which tends to hold the men, makes them more contented and happier and is evidence of an earning power greater than in many lines of industries, and the result is that we do not have to give any particular thought to housing conditions.

We all envy such a happy state of affairs.

From a thriving New York city the Broadhead Worsted Mills write us:

We have only three or four houses and do not believe in building houses for laborers. We have a class of labor a little above the average, who build their own homes. Jamestown is noted for its laboring people owning beautiful homes. When an employee owns his own home and is interested in the city where he lives he will stand by the company that employs him much longer than he will if he lives in a tenement house belonging to the company.

The experience of the general manager of one of our largest collieries confirms the views expressed. He says:

From close observation and study of results experienced at fourteen operating collieries, I can state specifically that where housing conditions excel there the better class of labor exists, as is demonstrated by higher efficiency in their work, cleaner play during their play time, and better homes for the wife and family.

At such of these collieries operated by this company and where conveniences of a modern character have been placed at the disposal of workmen and their families, our labor is of the most efficient and also of the most stable character. We have found under these good conditions that even though the man did not fully appreciate the conveniences provided, in a great many instances after he and his family had moved away the wife has written to our superintendents asking if her husband can be placed at work again, and if a house can be obtained. At other of our collieries, especially those acquired by purchase after housing plans had been fully developed under the previous owners, we have observed that where inadequate thought and consideration had been given to house plans and conveniences difficulty was experienced in retaining the desired class of labor, even though the

working conditions at the mine were equal to the working conditions at our collieries built throughout by ourselves.

Another colliery has had some interesting experiences to relate in keeping men by means of improving their houses.

Our company is engaged in mining bituminous coal, and has over one thousand houses. Owing to the depressed conditiou of the trade for many years we were unable to keep our houses in proper and attractive condition, and had it not been for that condition prevailing generally, we would unquestionably have lost labor that otherwise we retained. During 1916 and 1917 we put all of our houses in very much better condition and improved the surroundings. We have not any doubt that we have retained labor which would have gone to other places had we not done so, and our judgment is that it is wise to provide comfortable houses and attractive surroundings for the employees of any industrial establishment and that such a policy returns indirectly satisfactory financial results in the operation as a whole.

It is only fair to record adverse opinions. From a large te..tile concern in Moutreal we learn that company housing is a disadvantage to them.

It makes them independent; if the company had not built they would have built their own homes and become fixtures.

Mr. E. H. Barnes, superintendent of the large General Electric Co. works at Fort Wayne, Ind., writes us:

This is a town where a great many people own their own homes, or are buying them at the present time. After these have got located then the outsiders float in and out. Of course, with the abnormal growth of our concern in the last two or three years without any corresponding increase in the housing facilities the matter of overcrowding and indifferent housing naturally makes it rather difficult for people seeking a new place to work and live. Our ratio of people hired to those kept has run unusually high in the last year. This we find it impossible to analyze; as automobile and munition factories slowed up we probably got the result of their culling out dumped on us at that time, due to our geographical location, but we have no data to prove or disprove this.

The question of companies building houses and renting them to their employees is one which very few people seem to agree on. Personally I think that any company makes a mistake in doing this. The working people as a whole suspect some ulterior reason for the company's apparent beneficence. To the average American, who usually has very fixed ideas about these matters, it is more or less repugnant.

From another metal-working firm we have:

We know that good housing tends to hold the men, as we find that many men give their excuse for leaving us that they cannot always obtain the kind of a house they desire.

Another of our correspondents emphasizes the importance of employees living within walking distance of the plant.

A Buffalo manufacturer's evidence is interesting.

We find that our most contented and steady, and probably best paid employees are those who live within walking distance of our plant.

Our main difficulty at this time in getting and holding employees is that the transportation problem would be largely solved by better housing conditions in the vicinity of our plant.

The opinion of Mr. A. W. Sanderson, Director of Labor of the B. F. Goodrich Company, Akron, Ohio, is doubly interesting because of the great outlay made on housing by the Goodyear Company in that city. Mr. Sanderson writes:

We have at times felt that if housing conditions were better throughout the whole city of Akron, turnover might be somewhat reduced, but we have never felt that any participation in the housing scheme would benefit us sufficiently to justify the undertaking.

Mr. R. S. Childs writes regarding the financial value of good housing:

At Marcus Hook, Pa., is the Viscose Company, makers of artificial silks, with a pretty housing development which takes care of about one-half of the employees. They have a labor turnover of 15 per cent per month at the present time. Next door to them is the Congoleum Company, making floor coverings, with no housing and the turnover is 30 per cent per month. The Viscose Company employs a larger proportion of skilled labor than the Congoleum Company. Living conditions in that region are very bad and labor is very restless, due partly of course to the great shipyard developments. The Congoleum Company recognizes the need of housing as the only solution of their manufacturing problem and figure they would save $200,000 a year thereby, inasmuch as they have unskilled labor handling fragile goods where a careless sweep of the arm will ruin $20 worth of goods.

Further confirmation from an Erie Iron Works:

Among our mechanics who own their own houses the labor turnover is very small; this also is true to a large extent among the unskilled labor who have lived in the city and own their homes.

The president of a large paper company near Philadelphia testifies to the steadiness of home-owning workmen:

Our industry is the principal one in the town and most of our employees have been with us for a great many years. There seem to be enough houses in the neighborhood to provide room for all. The company owns some land which it sells to those employees who want to buy and build their own houses. We sell the land at a low price and on any terms which the purchaser may desire. We encourage our employees to buy their own homes, as our experience is that those who do so are much more dependable than those who do not. Our relations with our men have always been most pleasant and all of them take a personal interest in the property and success of the business.

Another Massachusetts textile concern is desirous of seeing his men home owners independently of his company:

As a general proposition there is no question but what good housing near the plant is a benefit to any manufacturing business located in the country. We are under the impression, however, that good housing built by other people is of more benefit to the community and the manufacturing plant than housing controlled by the manufacturing plant itself. We are continually having to build more tenements, although we find that tenements owned by other people usually rent more readily and for more money than our own houses.

There seems to be distinct desire ou the part of our better class of employees to spread out and not house themselves as thickly as in years past. Among some of the Southern European aliens, however, the tendency to overcrowd still persists.

We believe that a plan that enables the employee to build and own his own house is a benefit to the community, to the employer and to the employee. We have not, however, been successful in interesting our employees in any proposition of this kind to the extent we have desired.

A well-known crane manufacturer believes in selling houses to his men even at a loss:

From the fact that nearly all of the company capital is needed in its business it is a very difficult matter for them to divert much of it to the construction of new houses, much as they would like to do so.

We find that the employees were very anxious to buy these houses, but of course, the burden of the expense will have to be carried by the company for approximately ten years.

We consider it desirable to have as many of our employees own their homes as possible, because it makes them more thrifty and their families are better satisfied ordinarily, because of the added interest.

The pressure of the housing situation is very apt to make it necessary for us to utilize women in the shop to some extent. The fact that they are already housed makes it easier to use them than to get help from outside sources and then have the housing problem get more serious than it is at present.

While we have no definite statistics relative to the time lost by men who are properly housed and those who are not, we are of the opinion that a man working to pay for his own home will not lose any more time than is necessary and therefore will be on

the job as steadily as it is possible for him to be. The satisfaction of owning one's own home and improving it is real. So far as we can recall we have only had one man who has bought his home leave the employ of the company in the past three years.

The houses which the company built during the past year were sold to the workmen for considerably less than the actual cost of them; however, the difference between the actual cost and the selling price of the houses will not be lost in the long run, because we feel that the men will be better workmen and will stay longer with the company because of the situation.

Many can sympathize with the following frank admission:

We were of the opinion that it would be beneficial to house our employees located in good houses in the village, and bought a large tract of land with that end in view, but gave it up for a bad job and have not done any building of that nature for some time, and would be glad to sell all we own or to hear they were burned up.

Our correspondent did not enlighten us further. In face of the successful work done by other concerns we suspect that some initial error was made in the organizing of the project. Such a letter only emphasizes the need for careful organization and management in a housing development.

Mr. D. H. Andrews, President of the Boston Bridge Works, lays stress on the laudable desire of the workman to make his own home arrangements:

For the great mass of people human welfare seems to consist largely in comfortable, healthful homes with income enough to provide food, clothing and some provision for the future, with a reasonable amount of recreation. The undisturbed possession of comfortable, healthful homes is such a prime factor in the contentment of employees that every far-seeing employer should and would, if circumstances will permit, have a deep and personal interest in this phase of the welfare of employees. Our experience with employees is that generally if the location of their employment will admit of it, they prefer to settle the question of their homes independent of any consideration which may, to them, savor of paternalism on the part of their employers. If the employment is of stable permanence and the employer can provide homes for employees with an arrangement for the gradual rental purchase of same by the employee, that would seem to relieve the laudable sensitiveness of the employee and to promise the best solution of the housing problem.

This can be done in a big metropolis. It is not so easy in the smaller towns.

Another believer in company housing anxious to "control" his men writes from Pittsburgh.

We have a great number of plants. We don't attempt to house all our men at the plants, because they are all located near small towns, and a certain number of them are drawn from these towns, but we house as many men as we can near the works and are building houses just as fast as we can get employees to rent them.

We find it is best to have employees live near the works, and if you have them in your own houses, you can control them better. During the shortage of labor which we are all now experiencing, if we did not have houses near our plants, in many instances we would have been shorter of labor than we now are.

At one of our factories where we employ between two hundred and three hundred laborers, we house the majority of them. We have built practically the whole town.

As a general proposition, the writer has handled large lots of men direct for the last thirty years, and would, if possible, house every man on company property.

A contented Maine textile concern says:

We have been building a few houses every year or two and almost never lose a well-housed family.

An Ontario manager writes:

We think that no one at this time could deny the advantage arising from the possession of houses in which employees could be taken care of.

Unfortunately we haven't any residences in which to house our men, and the fact that we haven't operates against us because the town is crowded, and the first thing an out of town mechanic asks in answering our advertisement is about housing facilities.

This experience is borne out by a Connecticut metal worker who is building houses:

Not to house my present force—they are already located, but to add to my force by bringing in out-of-town men. They will not come unless I can find a home for them.

The general restlessness of labor is emphasized by many; for instance, Mr. F. R. Still of the American Blower Company, Detroit, Mich., writes us:

Proper housing conditions have a very decided influence on the turnover of the employees in any industrial institution. The best indication that this theory is a fact is demonstrated by plants located in very small places, where the rents are low or employees own their own homes. In all large cities where industrial institutions are numerous and mechanics are in great demand due to the scarcity of first-class mechanics, temptations are held out to the employees of first one institution and then another, which has a very decided influence in causing a spirit of unrest that leads to frequent changes of position, and it is hard to determine whether this is the deciding influence of the fact that housing facilities are adequate.

Undoubtedly if the employees in one institution have cheap rent or own their own homes, they are less inclined to move to some other institution, if the work and factory conditions are satisfactory. On the other hand, where rents are increasing from 25 to 50 per cent each year and the cost of everything is rising more rapidly than perhaps their wages are rising, they are naturally inclined to become restless and look about for positions that will pay them more than they are receiving at their present positions.

This view is indorsed by a machine shop in Providence who write:

We cannot attribute the labor-turnover problem which we experience to lack of proper housing. It is due in our particular case largely to a spirit of unrest. The operatives in our line seem to feel that they cannot work in one shop but about so long, and have to move along to a competitor, and finally come back to the old stamping ground for a period preceding another cycle of similar nature.

We are located in a community where good houses are available, and quite convenient to the plant. The company has not felt it necessary to consider entering into the house problem on its own responsibility, for this reason.

In our particular case, we doubt very much whether any house could be built that would hold our help beyond a limited period, unless it were a portable house.

A Buffalo textile firm says:

We have a splendid organization, and while there is considerable changing amongst our employees, particularly the girls, we think it is due to the existing unrest amongst the laboring class. Most of our employees live in the immediate neighborhood, and about 60 per cent of our entire staff has been with us ever since we located here in 1913.

The living conditions in the immediate vicinity of our mill are splendid, and we believe that this is one of the main reasons why we haven't experienced a labor shortage to any extent.

We, of course, realize that our possibilities of getting new and additional help are not as good today as they were when we located here; on the other hand, we have never been handicapped to any extent on account of being unable to secure employees.

In our estimation, good housing facilities have a tendency toward holding men that are married particularly; and the loss in time through sickness that our men have sustained is so small that it is not to be taken into consideration.

Mr. W. H. Ham, Manager of the Bridgeport Housing Company, comments on the prevailing "restlessness" and has some important and interesting suggestions to make.

Labor is restless at the present time. The single man is bound to be a rover. The young married man is somewhat better, but still has a tendency to rove and to seek better conditions and better wages because of lack of ties. The unmarried man should

be free from any restraints which would handicap his ability to advance himself. My feeling is that the best way to prevent roving of the harmful type is to build up the associations in manufacturing towns to such an extent that the unmarried man may have membership in proper kinds of associations, which will teach him to advance rather than stay still. Sports for both winter and summer are very important items. Winter sports are very lacking in most of the manufacturing cities. The competition in physical exercise is very keenly appreciated by the average working man.

I believe in the school for advancement of knowledge in the trade and the wholesome surrounding of a sufficient number of playgrounds so that we can have athletics for a very much larger number. This will have a great deal to do with the turnover of the unmarried man in the factory.

I believe the turnover among the married men with small families can be prevented by building attractive small homes (with emphasis on the adjectives that modify "homes").

A Philadelphia general manager attributes much turnover to errors in employing unsuitable men, stating:

It is the young, shiftless, irresponsible class who make the greater number of changes. Labor should be carefully selected and must be tried and culled in order to secure reliable workmen. I do not believe that any system of investigation will entirely or even largely prevent the misfits and dissatisfaction which frequently occur. A trial seems to be the only method for determining the matter finally.

This view is endorsed by the industrial superintendent of the Brown & Sharpe Manufacturing Co. Like all big city men he disregards the housing problem. He says:

The increased turnover in 1917 is due to military service and war conditions and has no relation to the housing question.

The main part of our experienced force has been stable to as great a degree as could be expected, the greatest turnover being among new and inexperienced help "hired out" to increase our force.

A Newark foundryman feeling the shipyard competition writes:

It is the shipyards that have made these men unsettled and continually dissatisfied.

The big wages paid by them have hurt many smaller manufacturers.

In the big centers the employer does not consider housing such an important element. From the Laboratory of Thomas A. Edison, Orange, N. J., Mr. Clark writes:

The Edison interests do not attribute any of their labor turnover to lack of proper housing. We are so situated that we draw our employees from a very thickly populated district, which does not make it necessary for us to house any of our employees.

Particular emphasis is made to the lack of proper housing at this time. This is due to the war work factories and shipbuilding plants that grow up over night. In these cases it is not a question of housing, it is purely a question of who pays the highest wages. The large labor turnover at this time is due entirely to what I might term competitive bidding for men's services, and the housing conditions are unquestionably a secondary consideration.

A well-known cement company is of the same opinion:

All of our plants with one exception are so located that a large proportion of the employees live in adjacent cities or towns. The plant which is the exception has the largest turnover of labor that we have and we are now building some houses we hope will better conditions.

An Empire State manufacturer has discovered another reason:

Adopt national prohibition of the liquor traffic, and many of the labor problems will solve themselves. Thousands of derelicts will never again be available to help do the world's work.

We suspect that the wish here is father to the thought, but we trust that if the drastic remedy is administered it will produce the expected cure.

Mr. R. L. Caldwell, well known to all interested in good housing, compares our care of our workmen to our care of our tools—to the disadvantage of the former:

Undoubtedly no class of Americans are more progressive generally than employers. They are keen for the quick adoption of any improvement in machinery, in facilities, in methods. Why is it that they are so slow to cultivate better relations with their employees, upon whom much more depends than on any machine? It cannot be because the question is difficult, for difficulties never deter an habitually successful executive, whose success lies largely in his ability to overcome difficulties.

Employees are very watchful of their machinery and take every precaution for its preservation and lubrication to insure its being maintained in good working order.

What would an employer think of a superintendent who scrapped 50 per cent or even 15 per cent of his complement of machinery per annum? Yet that this record is common in labor turnover is evidence conclusive that lubrication is needed in relations between employers and employees. To scrap workmen is expensive as every employee knows. New help is poor help. Inexperienced labor is inefficient labor, therefore costly labor. Low production per operative and per machine due to poor operatives means high costs in addition to low wages, so neither side is satisfied. Dissatisfaction results in more labor turnover and so the process continues interminably.

Here is a manufacturer in trouble. He states:

Our problem is housing single foreigners, who are more or less transient. They keep no heat during the day, freeze all water pipes, live without furniture, and have wrecking parties occasionally. Have suggested heated barracks with common lounging room, kitchen and food store, but they do not favor this on account of group likes and dislikes.

Experiences like this are common where proper regulation and inspection is not carried out. But the experience of the Octavia Hill Association and many others shows that even in the worst localities tenants can be made to live decently and treat houses properly.

CAUSES OF LABOR TURNOVER AS SHOWN FROM REPLIES

The general impression gained from a study of these and many other letters establishes the following causes of labor turnover today:

1 Improper or insufficient housing
2 Inadequate transportation
3 The general restlessness due in part to the abnormal war conditions
4 "Misfits"—lack of care in employing men for work for which they are best fitted.

An important cause not touched on by any of my correspondents is the lack of proper relations between employer and employee, under which heading I would include lack of supervision of the hiring and firing of men, lack of care or interest in the men, friction with the labor unions, etc.

We cannot state definitely which of these is the most potent cause of trouble; but enough has been said to justify the statements made in the earlier parts of this paper on the supreme importance of good housing.

The lack of good and sufficient houses is now recognized as a most important hindrance to the winning of the war. Because of it factories are losing men, losing work, losing output and losing profit. Losing men, because they will not stay when houses are unsatisfactory; losing work, because in many cases work has to be refused because of lack of help, and also losing output because of lack of men—and loss of efficiency in breaking in new men is a serious factor in limitation of output, and losing profit because of all these.

A Start on Solving the Problem

During the last six months this is being very generally admitted, but little has been done to remedy conditions. Speculative building and real-estate development have practically stopped and the manufacturer confronted with rising costs and war taxes has pleaded his inability to release capital for extensions like housing work, which do not show any direct profit. As a result strong pressure has been brought to bear upon the Government to provide funds for housing, which has resulted in \$50,000,000 being allotted to the Shipping Board and \$60,000,000 to the Department of Labor for improvement of housing and transportation facilities around shipyards, munition plants and the like. In England since the beginning of the war \$700,000,000 has already been spent and the future housing program in England runs into millions more, although the English housing problem has never been so urgent as it is here. It seems probable that the \$110,000,000 with which the Government will initiate its housing program will be but a small part of the capital that must be invested by federal or state governments or by municipalities and manufacturers in the near future.

The Workman's Home: How It Should Be Built.

One of the striking things that investigation of housing conditions brings out in almost any city, is the unsuitability of the type of houses to the inmate. It seems that houses are hardly ever built to suit the needs of the working man, but those above him in earning power or standards of living. When such houses become dilapidated or neighborhood conditions change he enters the houses and adapts himself to them as best he can. Comparatively few workingmen need a six- or seven-room house or can afford to occupy them without subletting half of the house or taking lodgers.

Some of the worst housing conditions we find are in old mansions left stranded by the receding tide of fashion and now occupied by four or five families, all sharing the same toilet and water supply.

The experiment is now being tried in many localities of building three- and four-room apartments, and four- and five-room houses with much success. The workman as a rule does not desire to have the privacy of his home invaded by lodgers and welcomes the opportunity to live in a small house or apartment without them.

Any discussion of the kind of house he requires should be prefaced by a statement drawing a distinction between the skilled workman and the unskilled. The former are usually Americans or live according to American standards; the latter are mostly foreign-born or negroes, receive lower rates of pay and do not desire, or if they do desire, cannot afford all the refinements and conveniences that are usually built in the American home.

I have been criticized for emphasizing this; particularly by those who are working for the Americanization of the foreigner. I sympathize with those who seem to see in my suggestions a lowering of the American standards of living, to which all should aspire and eventually be raised, standards that I endorse and ideals that I stand for also; but I stand my ground, realizing that the goal we aim for cannot be reached at one bound, and if we insist on building only that type of house which we think is ideal we shall be of no help in relieving the wretchedness of the present generation of unskilled workmen and their families. They may look with longing at the accommodations being built for them but they cannot afford to enjoy them and have to be content with the overcrowded tenements and old houses of divided occupancy that they now live in.

There is a certain minimum however that we all agree should govern the design of any workman's home. He should have at least one living room for general use of an area not less than 150 sq. ft. entirely separate from his sleeping rooms, and he should have enough bedrooms for himself and for his children of different sexes to sleep apart, each bedroom having at least 400 cu. ft. of air space per occupant, and every room having direct sunlight and ventilation through windows of ample size. Every tenant should have his own private toilet equipped with water closet and bath tub, and a sink with running water in the kitchen; and all plumbing should be connected to the sewer and pure water for drinking be supplied through faucets in the kitchen and bathroom.

American standards demand in addition separate parlors, separate dining rooms, pantries, large cellars, porches, furnace heat, electric light, laundry tubs, lavatory bowls, etc. All these are desirable and should be provided if possible, but it is better to build whatever can be got for a reasonable cost than to add all these things and make the cost so high that it is out of reach of the tenant.

In discussing types, methods and materials of construction ought not to be omitted. The difference in first cost between good construction and poor construction is not great and is speedily amortized in reduction of repair bills.

It seems to be fairly certain that the Government will build only permanent houses. It is not at all certain that these will be sold to the occupants and it is very necessary that the construction should be sufficiently good to make a good security for a long-term mortgage or sinking fund. The better the construction, the smaller the depreciation and the better the security.

The difference in cost between a six-room frame house and one of brick, concrete or tile is at present prices less than 15 per cent. The price of the lot is the same in either case, so that the difference between a frame house costing \$3000 and lot worth \$600 and a brick house on same lot would be about \$450 or 8 per cent. Assuming 5 per cent for interest, the triennial outside painting would more than repay interest in his extra investment. By setting a lower rate for depreciation and amortization, it is possible to rent such a house at as low a rate as a frame house of the same size.

The Bureau of Industrial Housing and Transportation of the Department of Labor, created for the purpose of providing living accommodations for workers at munition plants and other establishments having Government contracts, has adopted a series of standards for permanent construction that will be enforced as to all the housing to be provided under the \$60,000,000 appropriation granted by Congress.

Nine principal types of houses for permanent construction have been adopted, as follows: Type 1, single-family house; type 2, two-family house; type 3, single-family house with rooms for lodgers or boarders; type 4, lodging house for men; type 5, hotel for men; type 6, lodging house for women; type 7, hotel for women; type 8, tenement house; type 9, boarding house.

All row or group houses are restricted to a depth of two rooms. No living quarters will be permitted in basements. Brick, terra cotta, stone or concrete will be preferred. Fireproof construction will not be required, but roofs are to be fire-resisting. (*The Iron Age*, May 16, 1918, p. 1270)

MANUFACTURING IN RELATION TO BANKING, RESEARCH AND MANAGEMENT

By WALTER RAUTENSTRAUCH, NEW YORK, N. Y.

Member of the Society

PERHAPS there has been no other time in the life of our nation during which the social and economic problems confronting us have been so vital, so perplexing, and of such colossal magnitude as those which confront us now. Nor have there been such times as these not only to test the strength of our material resources, but also to prove the good and the bad in the articulation and functioning of the elements of our business system through which our resources are created and distributed. Our engagement in this most gigantic of wars is serving not only to present new and more perplexing problems, but also to emphasize the needs and accelerate the demands for an entire reconstruction of our whole business and social relations. Not only are we compelled to bend every energy to carry to a successful issue a campaign for principles by which nations may live in harmony and peace, but circumstances demand that we also reconstruct the foundations upon which shall stand economic and social institutions capable of leadership in the new world which shall rise from the ashes of the old.

Under most unusual circumstances, therefore, are we required to seek solutions for difficulties which even in normal times would demand the keenest minds and the strongest characters to accomplish.

Many agencies, governmental, industrial, and corporate, are at work in an endeavor to adapt present facilities and create and operate new facilities for carrying on the business of war, and not only for war, but also for the many perplexing industrial, agricultural, and social situations incident to the problem of living, which the war has seriously disturbed. We have vast potential forces, which are matters of just pride, but we are thankful that we are conscious of our weaknesses and inexperience and that we recognize the difficulties and failures which surround us. The many heated debates in the councils of our leaders and criticisms in the daily papers on the conduct of governmental and industrial affairs make us more and more conscious of the need of a business system which is more fundamentally sound and the need of higher ideals upon which such a business system may successfully be founded. We have long held the reputation for wastefulness which abundance of resources creates. The quick acquisition of wealth without the moral strength of character which arises from the toil and sacrifice of production has raised up many leaders who predominate over the controlling forces of our civilization and tend to destroy right standards of service and create false standards of living. The reflection of these influences in the conduct of affairs has occasioned much waste in resources and effort and created many of these problems which confront us today.

But as we contemplate the many instances of waste in resources and effort which accompany our endeavor to carry this war to a successful issue, we find that the inherent nature of the conditions by which these wastes occur is no different than that which many of us have observed in normal times, only in a lesser degree. It would seem that our failures reside in these particulars:

1 Individualistic effort as opposed to coöperative effort

2 An undue regard for the might of "purchasing" power as opposed to the might of "creative power"

3 A lack of appreciation for science or the scientific spirit in the conduct of our business system.

The introduction of corrective measures which will enable us to counteract and reconstruct these tendencies reaches every field of human endeavor, and the very nature of the changes demanded positively indicates that this must needs be. We are dealing now with an attitude of mind, the creation of a philosophy, if you please, upon the foundations of which we hope to rear an economic and social machine which will withstand the onslaughts of a world catastrophe—indeed, by means of which such catastrophes may be made impossible.

In every movement or effort to betterment there are certain avenues of approach or mediums of operation through which most effective results can be accomplished, and as we review the problems before us and the particular institutions factoring therein, it seems that among these the manufacturing industries take a high place. Any right effort to place our wealth-creating agencies, as represented by the manufacturing interests, on a higher plane and in proper coördination with other controlling factors of our civilization will render a lasting service to mankind. A close analysis of the manufacturing problem will indicate that corrective measures must be applied both from within and without the immediate province of the enterprise. It will be our purpose to consider three particular avenues from which relief may come, and these are in:

1 The closer relation of our banking institutions to productive enterprises

2 The closer relation of our universities and educational institutions to the industries

3 A broader conception of responsibilities in the management of factories.

1 Relation of Banking to Productive Enterprises

For many years the economics of barter and trade have so engrossed the interest of capital that the opportunity of profits in dealing with what others have produced has overshadowed any interest in the economics of production and the obligations of capital toward it. Wealth distribution and acquisition therefore have become of primary importance in our industrial philosophy, while the wealth-creating agencies have been factored to only a limited degree. Only as necessity has forced the issue, and not as a matter of fundamental policy, have the wealth-producing agencies been raised to the plane of excellence which their value demands. This attitude of mind is well reflected in the usual methods employed by banking institutions in extending their credit facilities to those engaged in productive enterprises. Because of their obligations to their depositors, the banks have had to have regard for the quick assets of the borrower, so that the acceptance of all customers' notes is primarily conditioned on this particular.

Abstract of paper presented before the Philadelphia Section of The American Society of Mechanical Engineers, November 27, 1917, and before the New York Section, January 8, 1918.

Indeed, sound banking demands the customer's liquidation of obligations at stated periods, and for this reason the customer's possession of quick assets has been the deciding factor in credit extensions. When we realize that about 4 per cent of the daily business transactions of this country are conducted in money or currency and 96 per cent are recorded in open account credits, checks, notes, and bills of exchange, and that a disturbance of this ratio, say a demand for 10 per cent cash settlement, will inaugurate a panic, we appreciate that emphasis in the matter of the borrower's quick reserves is well placed.

While the Federal Reserve Board is causing our banking institutions to have more regard for the borrower's ability to liquidate his banking obligations at maturity, its influence is

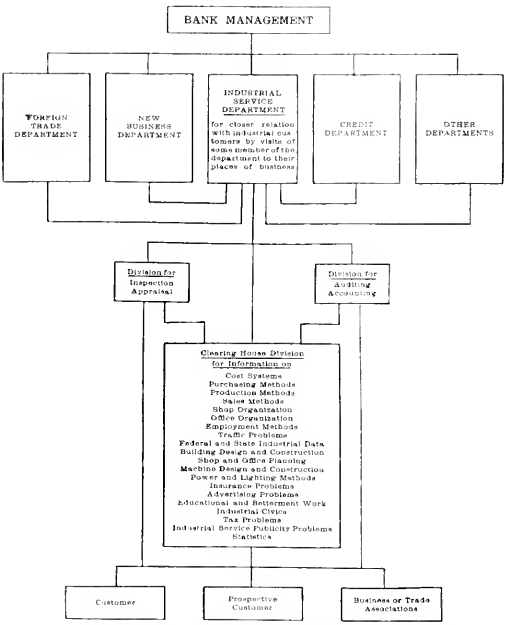

Fig. 1 Organization of Industrial-Service Department, National City Bank of New York

such as to point out that this ability does not alone rest in the possession of quick assets, but that it is also dependable on certain factors which condition the life and prosperity of the enterprise itself. Wealth-creating ability as represented in factors which every engineer understands is being appreciated, together with purchasing ability as represented in readily convertible assets. The inauguration of credit control through the medium of the Federal Reserve Banks, therefore, has not only served to promote a more sound banking policy in the matter of credit extensions, but it is also causing the more progressive bankers to view seriously the whole banking problem in relation to industrial enterprises. In other words, there is being created a larger sense of obligation and of opportunity to serve the industries that through the closer coöperation of the two both may grow into stronger institutions.

Not only has this influence been working in the relation of banks to manufacturing industry, but also in their relation to the agricultural interests. In this instance it is particularly true that the foundation of credit must rest on anticipations which are realized through sound business methods, and therefore the banks are compelled to interest themselves in this phase of the borrower's soundness.

Instances of coöperation between the bankers and the productive industries evidence an awakening to opportunity in which we may take great hope. Not only is there a recognition of a "more business-like application of credit" which rests upon the fundamental laws conditioning the prosperity of the wealth-creating industries, but there is also evidence of a real spirit of interest and helpfulness, in that there is maintained a personal and intimate contact through scientifically-trained bank representatives.

In the field of industrial banking we have also just reason to feel that an appreciation of the broader field of usefulness of banking facilities is being felt. Under wise leadership the National City Bank of New York has inaugurated an industrial-service department which it is believed will have a most helpful influence in the field of industrial development.

In establishing this new department of "Industrial Service," the bank hopes not only to increase the usefulness of its banking facilities to business by adding to its means of recognizing and crediting merit where credit is due, and thus to blaze the way for more constructive coöperation between banker and client, but also, by placing the emphasis on better methods of doing business, to help swell the tide of interest in scientific cost-keeping and more efficient management—regarded by keen observers as essential to our success in the worldwide economic struggle certain to follow the present war. The chief effort, therefore, of industrial service will be exerted along strictly coöperative and educational lines.

With the permission of Mr. Schwedtman, of the National City Bank, is presented herewith in diagrammatic form the embodiment of the new Industrial Service Department in the scheme of the bank's organization.

A study of this chart will show quite clearly the thorough manner in which the bank is prepared to be of specific help to the manufacturer in every field of technical and financial service. A new industrial philosophy is springing into being, and the spirit of intelligent helpfulness is guiding our endeavors to establish more firmly the foundations of our national welfare and growth.

2 The Relation of Our Universities and Educational Institutions to the Industries

It is impossible to record the development of our manufacturing institutions without bearing testimony to the labors of the scientists whose investigations and researches have been the very cornerstone upon which the industries are founded. While this is so obviously true, its significance is not always realized, and there has accordingly developed in many quarters a departure of the industry from the help of the scientist and a failure of the scientist to coöperate with the industry. Consequently the scientific spirit or attitude of mind is lacking in many of our industrial institutions, and the engineering and scientific schools where the activities of the scientist are largely confined have not always embodied those methods of operation which make apparent their industrial usefulness.

The time has passed, if indeed it ever has been, when the industries and the engineering schools can come to their full possibilities without close coöperation. The separation of the two institutions, whose technical interests at least are one, has been a loss to both in spite of the rapid development of each. The men coming from our schools have not been as well

prepared for immediate usefulness as they might have been, and the industries have failed to profit by the results of scientific discoveries which have never become known beyond academic circles. In fact, one of the greatest services to be rendered by our engineering schools lies not so much in the discovery of new facts and principles as in the introduction in the industries of many scientific discoveries dormant in the archives of the scientist, the commercial possibilities of which have never been appreciated. The patient search for scientific laws and principles underlying industrial processes and economic relations by those skilled in methods of research, and, moreover, the careful and judicious application to an almost limitless field of human endeavor of the already established facts and laws which have never been put to effective use, together with the preparation of highly skilled engineers capable of making and supervising these applications, is a plane of usefulness to which our universities must rise that they may take their proper place in the development and growth of our nation. Here, also, the obligations of this development lie both within and without the academic walls.

While engineering is highly technical, it is essentially an economic study. Just as the banker operates through the medium of bonds and stocks and is successful as he understands the laws which condition their value, so the engineer operates through materials, machinery, and men, and is successful as he understands the laws which condition the existence and prosperity of manufacturing institutions. While the most direct effect of engineering education in the past has been its contribution to purely scientific facts and principles, to the exclusion from consideration of those conditions under which these may be commercially useful, the economic necessities of the industries demand that we modify both the content and the spirit of the subject-matter handled and more closely parallel the economic requirements of engineering practice. The tendency in our engineering schools today, therefore, while emphasizing the necessity of excellence in the treatment of scientific facts and methods of analysis, must be increasingly toward that commercial and economic treatment which is so essential to an adequate knowledge of the use of science in engineering service. We find, accordingly, that those subjects in engineering instruction which were formerly thought to have their sole foundation in the sciences of physics, chemistry, and mathematics, and which conveniently admitted of formulated treatment, must be modified in their presentation to the inclusion of questions of cost and the influences of economic environment. Though it was once believed that, because engineering practice required a knowledge of scientific facts and principles, instruction in these alone was a sufficient preparation for the practice of the profession, it is realized that this is not sufficient, and that a knowledge of the economic adaptability of facts and principles is of equal, if not of greater, importance to an adequate understanding of engineering practice.

Accordingly, while formerly a student was taught to manipulate with the mathematics of thermodynamics in explanation of the behavior of steam in an engine, instructed in the principles of performance of waterwheels through the sciences of hydraulics and mechanics, and shown how to compute the stresses in a framed structure through the principles of graphical statics, he must now be taught, in addition to these, that the cost at which power may be generated is determinable by clearly defined principles and laws by means of which he may decide whether a steam-power plant or oil-engine installation or water-power development, each with a given type of housing structure, is capable of producing power in this locality or that locality with minimum cost of investment, depreciation charges, and cost of labor and materials, and will operate to satisfy a real demand and justify its creation. He must learn not only how a machine pattern is made by some method selected for demonstration by the instructor, but also that it may be made in a variety of ways, each of which is justifiable according to the quantity of production, demand for rearrangement of parts, adaptability to economic methods of molding, and to other conditions affecting the cost of producing castings by it. Not only should he learn to determine the proportions of machine parts to suit the loads imposed upon them, but also that the proportions must be modified to permit the part to be duplicated in a series of sizes of a given class of machine, or to facilitate founding and machining operations, that the completed machine may be supplied to the market at a price and in competition with other manufacturers of the same class of goods.

These attempts of our engineering schools in the past to make the instruction in engineering subjects more nearly representative of standard practice have met with more or less success, depending on the closeness of contact of the instructors with engineering practice and their ability to incorporate the spirit of engineering in methods of instruction. The effect of a proper amalgamation of the purely scientific and technological aspects of engineering with the economic and commercial principles upon which successful practice is founded is to create in the student that sense of proportion and judgment which tends to economize his efforts in contributing to scientific progress and invention. Not only will he know how to proceed to judge the scientific feasibility of a project, but also to determine what commercial limitations make a scientifically possible project impracticable; and, moreover, if he has that rare spirit of inquiry developed by proper methods of instruction, he may be able to determine that commercial limitations in a given field of practice exist because of an insufficient or entire lack of knowledge of scientific facts and principles, and thus be led to an investigation of scientific foundations the successful issue of which may be a most important contribution to the revolution of engineering practice in a given field.

Perhaps the most striking instance of this latter kind of scientific investigation is that conducted by the late Dr. Fred W. Taylor. His studies in the ancient art of cutting metals and the discoveries resulting therefrom have not only caused the redesign of nearly all of our metal-cutting machines to the improvement of their functional characteristics, but have completely revolutionized the methods of machine-shop management, the influence of which is felt in many quarters not at all concerned with engineering processes.

But this attitude of mind necessary to a proper conduct of an educational campaign for industrial betterment cannot develop without the coöperation of the industries themselves. We may inquire, therefore, into the nature of this coöperation demanded and the ways in which it may be accomplished.

For many years we have been accustomed to look upon the work of the Department of Agriculture as rational and necessary to the development of our agricultural resources. Through the operations of its agricultural experiment stations in every state in the Union, its scientific laboratories and the work of its trained investigators at Washington, and more recently through its trained agricultural agents in every district of the nation, the department has been of invaluable help in promoting the most efficient methods of crop and livestock production.

When we seek for the same evidence of coöperation between science and industry in the manufacturing field, we find that no organization of this sort is to be found. There is, of course, good evidence of individualistic effort in many quarters, both in research and in the promotion of better methods of production, yet there does not exist the coöperative effort which the importance and value of the industries demand.

It may safely be estimated that the capital invested in manufactures is perhaps \$25,000,000,000, and the annual value of manufactured products of all sorts nearly \$30,000,000,000. Approximately 8,000,000 people are employed in the strictly manufacturing industries, and the value added through their labors is nearly \$12,000,000,000.

Surely the economic importance of our manufacturing interests, as above reviewed, indicates a real demand for organized scientific effort to conserve and develop to its fullest possibilities this strong right arm of the nation.

Those industries which could afford industrial research laboratories have demonstrated their value beyond doubt. The wonderful laboratories of the General Electric Company, the Eastman Kodak Company, and others with abundant means, are counted among the big assets of the organization, since they have materially contributed to the strength of these institutions.

It is in such times as these, when all industries, both great and small, are depended upon for the creation of those products which our recently established \$19,000,000,000 credit hopes to purchase, that we realize the need of helping those who surely need the assistance of industrial-development laboratories but cannot afford the investment or maintenance charges. In this connection it is extremely interesting to note the following paragraph from a recent issue of a New York newspaper:

"COÖPERATION IN RESEARCH

"*British Way of Bringing About Progress in Industries*

"Realizing that many industrial firms are barred from the benefits of scientific research into their particular lines of activity by the great cost, reports Consul Franklin D. Hale, Huddersfield, England, the Committee of the Privy Council for Scientific and Industrial Research proposes the introduction of the coöperative idea. In this way a firm that is unable to bear the entire expense of research could contribute to the cost and share in the benefits accruing to an industry as a whole. It is planned to establish trade research associations in England, to be formed as needed for each industry or group of industries, and aided by certain funds which the committee has in charge. One association is about to be organized for the cotton industry, and others will be formed as soon as possible for the wool, flax, oil, and photographic industries.

"The work that has already been accomplished through the committee's efforts, according to Mr. Hale, includes the discovery of three kinds of optical glass, the investigation of light alloys for use in aircraft, and the production of a new hard porcelain from purely British raw material. Researches into the recovery of tin are expected to save that industry a very large amount each year."—*New York Times.*

All phases of this subject cannot be considered, but it is sufficient to point out that the particulars of this need for industrial betterment seem to reside in the creation of industrial-research facilities and in the training of men through whom research may be conducted and introduced in the industries. In the last analysis the successful issue of this project must rest primarily upon the training of men, for not only must better production methods be discovered for particular industries, but there must also be those who shall actually introduce and operate them. Quite clearly, therefore, does there seem to be an obligation resting on the universities and the industries which can only be accomplished on a high plane of coöperation.

In what form shall this coöperation exist, and what shall be the specific means through which it shall become effective?

Of the several possibilities which suggest themselves, it seems that most fruitful results will follow from the establishment at our universities located in industrial centers of industrial development laboratories, to which all industries, both great and small, may have an equal access. The endowment of these laboratories that they may be independent of any income from specific industrial interests is absolutely essential to their free development and operation. With the establishment of such facilities there can be little doubt but that the great potential energies of our universities can be made directly available to the improvement of industrial processes. Not only will this be of benefit to the industries, but it also will react favorably to the universities and stimulate productive scholarship and scientific research which will be felt in every field of human endeavor. It is believed that these laboratories will soon demonstrate their usefulness in the manufacture of every commodity, and, although their introduction into the university organization must be gradual, it will not be long before the demands of the industries will require an equipment and organization which will compare favorably with that now possessed by the agricultural interests. A conception of what these laboratories may be, may be obtained from the illustration published in THE JOURNAL, June 1917, p. 547.

Together with the investigation of the technical problems of the industries, these laboratories must also fully consider the methods of organization and management by means of which the results of industrial research may be effectively employed in the industries. Therefore it is believed that such a project as this should also serve to promote better methods of management through which industrial-process development may most effectively be realized.

3 BROADER CONCEPTION OF RESPONSIBILITY IN FACTORY MANAGEMENT

So much has been written on the problems of production, both in regard to their general aspects and in relation to their specific solutions in particular cases, that it seems as if enough had already been disclosed upon the basis of which successful procedure in particular industries might be formulated.

For the past twenty-five years there have been accumulated volumes relating to details of facts, methods of analysis, and routine organization plans for the effective conduct of tool rooms, stock rooms, planning departments, general offices, specific production departments, and for the efficient use of men and machines. There is scarcely an industry about which literature of the above sort cannot be found. Unfortunately, however, we are so constituted that the creation of this literature is not alone sufficient to stimulate improvements in methods of production. In spite of the fact that information on methods of scientific cost-keeping can be had almost for the asking, the Federal Trade Commission has reported that only 10 per cent of our industrial establishments have a cost system worthy of the name. This lack of cost information is indicative of inefficiencies in processing and management which can be effectively controlled only through a knowledge of cost factors. Thus it appears that there is real need for an educational campaign which shall seek to establish as a basic prin-

ciple in American industries those methods and policies which have been so successfully tried in particular cases. And this campaign must be waged among those who are in positions of authority, who exercise the managerial function and are responsible for the policies which govern the business over which they preside. Engineers discuss these things among themselves, and institutions presided over by engineers benefit by these discussions, but there is not that freedom of association between engineers and financial interests which dictate policies to create a scientific attitude of mind in the management of affairs. While the engineer is in some measure responsible for this condition, nevertheless it seems that ownership interests must evidence a real desire for the acquisition of the engineering point of view before much real assistance can be rendered. Crises such as the present have broken down many forms of control based on inadequate knowledge of affairs to be controlled, and thus the value of the engineering aspect of industrial organization and control is being more adequately recognized. It seems, therefore, that one of the principal problems of the managerial function is to determine the basic prime variables of the industry it proposes to control and establish means by which these may be quickly and conveniently recorded and analyzed.

Under such methods the management will not be required to call in a department head and ask for a statement of affairs. This immediately makes known to the department head that the manager does not know what is really being accomplished, and his influence is accordingly lessened. If, however, these affairs are known to the management through adequate records, it will be possible for the management to call in any particular department head and tell him that his department is *not going to show results if present conditions continue*, why it is not, and what particular things must be remedied to obtain better results and how it may be done. There is nothing so helpful to the keeping of all divisions of manufacture up to a high state of perfection as the feeling that the management really knows what is going on and can be of real help when assistance is required. When the management adopts the attitude of real helpfulness and looks upon itself as the chief servant of the industry, then we will have made a great advance toward a more adequate control of enterprises. It is the duty of the management to foresee and prevent difficulties arising, and this can only be accomplished by the establishment of adequate channels of information on the factors which condition the success of the enterprise.

It has been the experience of many to learn of well-conceived schemes of plant management falling away from the plane of perfection on which they have been established and thus discrediting the value of scientific-management principles. This again seems to indicate the need of an educational campaign among those who are to be depended upon to operate and keep in adjustment the new machine by which manufacture is to be controlled. No one would expect a delicately adjusted machine to operate well in the hands of an unskilled mechanic, yet many highly developed plans of management have been expected to continue in good operation in the hands of unsympathetic and poorly informed foremen. It seems that those who are capable of conceiving the broader principles of management and devising means for their embodiment in industries have gone too far beyond the capacity of those who are supposed to coöperate understandingly. In any improvement in management methods there must accordingly be promulgated a sympathy and understanding on the part of those affected thereby. It is dangerous to proceed in improvements beyond this point, for the plant will soon drop back to the level of understanding of the force and the investment will be lost.

Employers must surely take an interest in the education of their men, for no progress can be made beyond the general plane of intelligence of the shop.

This can be accomplished through coöperation with trade schools, correspondence schools, and the industrial departments of the Y. M. C. A. No matter how excellently the scheme of management and the methods of operation may be devised, no permanent progress will be made nor results attained if the vitalizing influence is lacking. This sort of problem cannot be solved in terms of x and y, and its importance is great in proportion to its difficulty of formulation. It is the thing which holds men together and creates in them a real desire to coöperate. It prevents men from taking a secret pride in the downfall or failure of others. It makes each department head feel that he is there to serve every other department, and his success is measured in terms of real service and helpfulness. An organization without this spirit is dead and will never hold together for a long period of time. While, therefore, it is incumbent on the management to see that the best methods of operation are devised and the most reliable means of control are established, it is believed that these will never accomplish the desired result without a proper selection of personnel through which the real life of the organization may be maintained.

It is beyond the province of this discussion to consider the details involved in the formulation of methods of procedure by means of which these problems of management may be solved in any industry, for, while each kind of industry presents the same general management problems, the means employed for their solution are very often quite different, because of the nature of the commodity dealt with and local conditions to be encountered, and therefore these details are not particularly helpful. We wish rather to realize that there is lacking in American industrial life that conception of the management function which is the foundation upon which all successful methods of factory operation must rest. When the engineer is more intimately associated with our financial interests and the university is more closely identified with productive enterprises, it is believed that the resulting amalgamation will effect a change in attitude toward the problems of management which will inaugurate the creative measures necessary. It seems there must be a closer coöperation of all interests factoring in industrial development in order that a true perspective may be had of the scientific, financial and human elements of the management problem. It is believed that this must be effected by a campaign of education which shall include the man at the bench as well as those who control his environment.

A paper on the problem of labor turnover and its cost, which was read at a recent meeting of the executives of the Albaugh-Dover Company, of Chicago, and which is quoted at length by M. C. Hobart in the May 16, 1918, issue of *Power*, includes the following estimate of the cost of placing a new man at work:

For advertising	$0.50
For hiring and clerical work	0.75
For instruction	5.50
For wear and tear on machinery and tools	12.00
For loss of production	25.50
For spoiled work and mistakes	12.00
For accidents	3.00
For interest on extra equipment	0.50
	$59.75

MAN POWER: ADDRESS AT MEETING OF BOSTON SECTION

By J. PARKE CHANNING

Chairman of the Engineering Council

A SUBJECT of the greatest importance and of most serious consequence to the American nation at the present time—man power—was discussed at some length in an address delivered by J. Parke Channing before the Boston Section of the Society on the evening of March 16, 1918. Most favorable comment was elicited by this address, which is here given in abstract form:

We are probably accustomed to think that we are efficient in the United States, particularly when it comes to such things as mining and manufacturing. The conduct of the war has demanded in England and in France a complete readjustment of manufacturing methods and plans and today England is probably as efficient a country as there is in the world, not even excepting Germany. England is in a position in which practically everyone in the country is engaged in some industry necessary for the conduct of the war, and this has been accompanied by an increase in the efficiency of her tools and the efficiency of her man power.

In the United States we certainly have been efficient as far as machines and perhaps as far as methods have been concerned, but we have not been efficient in the utilization of our man power. The problem that confronts us today and will all the more confront us after the war, is to make our man power efficient. There is one thing in England that has permitted her to reach this condition of state socialism with comparative rapidity, and that is that practically all of her laborers are English. While an Englishman may be a strong union man and ready to fight his employer tooth and nail, still at heart he is a British subject, and when his country was in danger he rose to the occasion.

In the United States we have such an admixture of unassimilated foreigners that the problem is more difficult, and so far we have not been brought to the point of stress which has arrived in England. But if we are to carry the war to a successful conclusion and if we are to increase our efficiency after the war we must introduce methods which will Americanize these foreigners and give them our own point of view.

I wonder if any large number of you have read the so-called proposed reconstruction program of the British labor party. This program will of course be subject to a great many modifications before it is adopted by the party. It is very largely socialistic and has for its basis four principles, namely:

1 The universal enforcement of the national minimum
2 The democratic control of industry
3 The revolution in national finance
4 Use of surplus wealth for the common good.

If these four demands are carried out, then surely England will be a socialistic state. I am not prepared to say how much of this program can or will be carried out, but it shows the trend of thought of the laboring man in England. He realizes that when the war is over, unless the greatest care is used in the reorganization of the regular industries there will be an immense amount of unemployment, and that this, if unchecked or uncared for, will result in an oversupply of labor and, if the old standard is maintained, a corresponding diminution in wages. Hence his insistence on the first principle of a minimum wage.

In demanding democratic control of industry he has seen such good results obtained in war work that he sees no reason why this control of industry should not be just as efficient in after-war conditions.

In the third principle, the revolution in national finance, he demands that taxation shall be so adjusted that it will yield the necessary revenue to the government without encroaching upon the prescribed national minimum standard of life of any family whatsoever, without hampering production or discouraging any useful personal effort, and with the nearest approximation to equality of sacrifice.

The fourth principle of the English laborites is that the surplus wealth shall be used for the common good. They say we have allowed the riches of our mines, the rental value of the land superior to the margin of cultivation, the extra profits of the fortunate capitalists, and even the material outcome of scientific discoveries, to be absorbed by individual profiteers, and they demand that in the future a large proportion of this surplus shall be applied to the common good.

It is not for me, nor am I a sufficient student of economics, to pass upon this program. It has certain merits and I am only calling it to your attention so that you may see that just this same thing is liable to come up in the United States. And the trouble will be that the pendulum will very likely swing too far if the employer class in the United States does not give more attention to the laborer and see that his condition is improved. You, as engineers, are in the position to act as instruments for carrying out this necessary work. Whether it be in a mine or in a manufacturing plant, I believe I can say that today a large proportion of the managers and executives are engineers.

The question to bring clearly before us is, are we properly trained to bring about this improvement in our social condition to improve the living conditions of our laborers and at the same time to improve their efficiency? I fear that a great many of us are not. We may be good technical men but we are not sociologists nor psychologists. We understand production of kilowatt-hours from coal or from water power, we understand the machine by which it is utilized, but we do not understand the machine which produces our man power.

This week I attended a conference at Columbia University in which the question of giving the engineering students a course in human engineering was discussed, and I came away with the idea that the authorities were beginning to realize that this was of paramount importance and that this training must be given the engineering student before he can be turned out as a man capable of eventually holding a high executive position. In my opinion there never was a time when it was so necessary to impress upon engineers and engineering students the importance of this human side of engineering.

I wonder how many of you can tell me what trade unionism is—you men who have had to deal with unions and who have had strikes. The fact is that none of you can tell what trade unionism is, because trade unionism is not an entity but a term of broad generalization covering a great many distinct aspects of the labor problem. A few weeks ago I presume I would have been rash enough to have attempted to give a definition, but in the meantime I have read Professor Hoxie's work on Trade Unionism in the United States and my ideas on the subject have been much clarified. On reading it you would find

that trade unionism can be classified under two broad general heads, one giving structural varieties and one functional varieties. There are four divisions in each class and any one of the structural varieties may function in any one of four different ways. There is one basic and most important thing which you would realize, an ever-present fact, and that is, that the interest of the laborer and the interest of the employer are diametrically opposed, just as the interest of the buyer and the interest of the seller are opposed, and that from the very nature of things they can never be identical and that all that can ever be reached is a compromise. And who is better qualified to bring about this compromise than the well-trained engineering manager, who, with his broad knowledge and experience of both capitalist and laborer, is enabled to act as an arbiter or a judge and arrive at a decision at least fairly equitable? It is the engineers of this country who are in a position to solve the labor problem, or at least to produce a solution as nearly ideal as possible.

The claim is made in Washington that it is difficult to get executives for war work, particularly executives who understand the handling of man power. I am told that some of the new plants for war industries have been most carefully laid out, taking into consideration the routes by which material is to arrive at the plant, its progress through the plant and its method of removal, the supply of water, coal and other material, but in a great many cases no thought has been given to the handling of the men or to their housing. These have been left to a hit-or-miss adjustment after the plant was up.

In 1916, under the auspices of the Y. M. C. A., the first convention to discuss the human side of engineering was held in Ohio. They lay great stress upon the advantages which would accrue to engineering students if they had an insight into the mental operations of the laboring man, and this had been fostered by getting the engineering students to volunteer one or more hours in the week for instruction to laborers employed in adjacent plants. This instruction is either in the English language, in citizenship or in athletics. A man who has volunteered for this work and who has done it for a year or more, when he goes out into active life is a much more capable foreman than one who goes out from an engineering school and meets his first laborer on the job. Lately the National Americanization Committee of New York has been conducting a similar propaganda, sending to the various educational institutions of the country a proposed basis of a course on industrial engineering. This proposed course goes into the scope of industrial engineering, describes the problem and the field, and takes up the question of the engineering insight of the work in reference to plant building, its location, and the fundamental considerations in its construction; it also takes up the management and division of the work, the analysis of the costs, the machinery, the materials and the efficiency methods. It goes into the questions of employment, management, and the methods for hiring, promoting and transferring men. It also takes up industrial welfare, with the various incentives to the workman and the provisions for his health and recreation and for the vocational training of either himself or his children. It also gives him instruction in conditions outside of the plant—the housing of the men and the planning of the town, and the health and recreation and education of their families. It takes up the problem of Americanization and what shall be done to make our melting pot efficient with no dross, and finally it gives him instruction as to what has been done and what should be done in legislation.

You engineers who are college graduates should use your influence to see that courses in human engineering are introduced in your Alma Maters, if they are not already there.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Aircraft Production

To the Editor:

The trend of the criticism of our aircraft production lays great stress on our failure to turn out machines, and particularly the delay in the production of the Liberty motors.

Men who have been through the mill of organizing new industries, or making changes in the personnel or the product of an industry, know that the element of time is one for which there is no equivalent. Unlimited capital cannot quickly produce one of the most highly developed and intricate machines of the present time.

The airplane as a whole stands preëminent as one in which every element of design, workmanship and material must be the best; in fact, the present contest in the air is one that makes a supreme test and can only be satisfied by a supreme effort of each one of the designers, managers and skilled workers on the production side, combined with the ablest military aeronautical direction and skill.

We all recognize the importance of specialization for both the individual and the industrial plant, but we sometimes fail to give this matter sufficient weight in dealing with industrial problems.

We frequently make changes in the personnel or product of a plant without calculating the handicapping effect of such changes. Changes in either personnel or product must be warranted by very important demands. The degree of handicap of such changes is measured by the degree of special ability or skill that is required in the production of the product.

The airplane engine stands at the highest point that has been reached by man in his production of a machine in which each of the elements is subjected to the highest possible stresses. This approach to perfection can only be attained by the highest degree of special ability and skill; hence, the delay in production. This applies to the refinements of the design as well as precision of workmanship.

If many blunders have not been made in reaching the present stage of development, then our achievement at the present time will go into history unparalleled. We have had available the best men in each field of endeavor, but since this is a new art ninety per cent of these men have had no previous experience in this line of work.

The recent change in which the highest executive ability has been made head of the entire production plan is in keeping with the fundamental need of the aircraft-production plan. It gives it that stabilization in which alone stands our hope for success. It will prevent the disturbance of that natural evolution of the industrial plant that takes place when there is the minimum shifting in personnel and product.

This is particularly well known to industrialists, but difficult to explain to an investigating committee. The industrialist knows that the best way to obtain results under present circumstances is what we may call the natural way. The natural way makes the minimum change in the personnel and the working methods of each individual. It uses men as they are found in the organization.

A new industry always goes through two phases that are seldom fully anticipated. The first one, in which the aircraft industry is at present, is one that brings most serious disappointment. The second one, which is ahead of us, brings a happy surprise. Both are due to the same fundamental element and cannot be wholly forecast.

Experience tells us that it takes a great deal longer time to get a new industry established than is expected. This is due to the fact that industrial life rests on the functioning of the individual and the coördination of all the men in the organization, and although this is a fact borne out by many examples, yet the average board of directors in an industry is disposed to make important changes in the personnel of its executives, and this in turn frequently results in changes throughout the entire plant; and it is at this point that we must not blunder at the present time. No greater menace to our success in this war stands facing us than the mere possibility of our disturbance of the natural evolution that is going on in the aircraft industries.

This natural evolution will bring about the skilful operation of each worker at his task and the natural coördination of all forces.

The tendency to put in impractical inspectors carrying out impractical specifications must be scrutinized with greatest care. Important changes in the executives should be made in the direction of practical men rather than talkers.

Regarding the difficulty of getting under way, we have many examples. We have seen mammoth buildings erected in incredibly short time. We have seen these buildings fill with the best machinery and with the best men of the country as executives and workers. In the early stages of the development, as we observed the spectacular advance of getting together so much material, we failed to realize the full significance of the meaning of coördination, and we have overlooked the fact that a "going" industry is the result of continuity of action on the part of each worker and manager.

Unfortunately, examples of this kind do not leave a permanent impression. We accept the facts when stated to us, and then as a people we go ahead and make the same blunder over again.

In the aircraft work I am confident that no such blunder is impending. The purpose of this, however, is not only to pay tribute to those who have been working effectively in this great program, but also to spread the gospel of stability of organization, the value of specialization, and the ultimate supremacy that will come to us if we will only follow along the lines that have been well established by our greatest industrial successes in this country.

Financiers have reached the point where they pin their faith on stable organizations. They know that success grows out of specialization, which carries with it standardization and stability of personnel, and they know that where there is continuously change of management or the "hire and fire" plan in the plant, or perpetual altering of the design of the product of the plant or the character of the work in the plant, these elements interfere both with the character of the workmanship and its profit making. They know that great successes are wrought by men who keep in mind this simple fact.

The highest and best production will be attained by each one considering it his patriotic duty to aid those under and over by the heartiest coöperation, for it is only by coöperation in the right spirit that we can hope to equal in organization an organization that is built up under a despotic government.

We are rich in resources of skilful workers, in material, and in highly efficient machinery, but our ultimate supremacy is facing a terrible menace in the tendency to make a change in management that will disturb the executives or workers in the acquisition of ability and skill in their new duties and tasks and will delay the coördination that is the foundation of an industrial organization.

To bring this matter closer to a concrete example, close observers of industrial economics know that in the machine-building industry it is practically impossible to design and quickly construct a satisfactory machine. They know that each new machine can only reach a satisfactory stage after it has been made in numbers and through a period in which each of the workers will have had an opportunity to work up a precision of operation and skill in the performance of each of the tasks.

This makes it impossible to make a successful machine in a short period, even if all the workers of the plant were available. This fact, that repetition of operations is essential, is the key to the whole situation; and they know that the condition in an industrial organization in which the work flows quickly through the plant without congestion at any one point is brought about by experience. It is aided by practical supervision and handicapped by impractical interference.

It is our work to emphasize the simple every-day rules of common sense on which have been based our greatest industrial successes.

We must recognize that Germany's success in the industrial world, previous to the war, and her present industrial strength are due to the fact that by nature and government continuity of action of the individual was the rule instead of the exception. During the thirty years of industrial progress of Germany there was an increasing trend toward specialization. We know, too, that it was specialization that gave America the leading place in the industries.

Growing out of our specialization there came into existence those who became specialists in industrial management. These men are of the greatest possible value to the Government if they are forced to bend their systems to fit natural law.

Our ablest young men have gone into this profession and have been rendering a distinct service, but their work must be coördinated with the natural flow of work from man to man that can only be discovered by experience in each industry.

It seems paradoxical that our best minds, our most patriotic citizens, those who have the highest esteem for man's independence and liberty, may in this critical hour, by methods that are scientific as far as they go, actually produce a result opposite to that for which they are working.

In times of peace a monkey wrench thrown into the gears of one machine in an industry, or a false scheme of management into one industry in the country, was not such a serious matter as it is today. Today this country is being transformed into one big industry for producing war machinery, and finds

itself associated with the Allies in a contest that is too difficult to risk any one element in our plan, and it is absolutely necessary to have a definite policy on this kind of management in order to prevent duplication of certain blunders that have been made in recent years.

Our successful industries have grown by natural processes and management that understood human nature. Some have had the benefit of the modern school of industrial management, and some have been seriously handicapped by it.

In this war program we should take no unnecessary chances, and from now on we should see to it that the plan of action should tend toward continuity of service for each worker in order to get that natural coördination that is necessary to accomplish results.

As for the ultimate outcome, we can confidently depend on results that will even transcend the statements that have been made by the optimistic who overstated the possibility of the early stages of the work. Each succeeding year will see America coming in with greater and greater force. This will be true if we adopt a plan that allows a reasonable continuity of action; but we will rise to our highest supremacy through our resources in man and machinery if we will follow the plan of greatest stability in personnel and product that has been demonstrated in our most successful industries.

James Hartness.

Springfield, Vt.

The National Sections Should Always Coöperate with Local Societies

To the Editor:

In comment on the paper by Mr. Louis C. Marburg on the new By-Laws governing the Sections of the A.S.M.E., recently published in The Journal, it may be worth while to emphasize further the idea that the development of the local sections of the national societies should by no means be permitted to interfere with the growth and development of the local engineering societies in various cities. All the national societies are now encouraging the building up of local sections or chapters, and it is universally agreed now that this forms the best means by which the national societies can be truly national and can avoid concentrating all their activities at their New York headquarters. If, however, it is attempted to maintain in any city of moderate size separate, independent local organizations of civil, mechanical, mining and electrical engineers, each meeting entirely independently with separate headquarters and staffs, the result would inevitably detract greatly from the strength of the local society.

Practically every one who has given careful study to the question agrees, I think, that in the building up and strengthening of the local engineering societies all over the country lies the best hope of strengthening existing organizations of engineers. In many cities, St. Louis and Philadelphia, for example, the problem was long ago successfully solved of establishing full coöperation between the local sections of the national societies and the strong, well-organized local engineers' clubs. Under such a coöperative plan, the different organizations are mutually helpful instead of competitive. Mr. Marburg clearly states the reasons why coöperation is helpful and necessary, and the committee of which he is a member has shown wisdom in so plainly recognizing the situation and providing for it in framing their By-Laws for the conduct of the A.S.M.E. Sections.

Charles Whiting Baker.

New York, N. Y.

The New Local Sections By-Laws

To the Editor:

The address by Louis C. Marburg on the new Local Sections By-Laws of the Society which appears in the March issue of The Journal is to my mind one of the most important papers which has appeared in its pages for a long time. It points out the fact that our Society is for the benefit of the engineer, no matter whether he is located in New York City or in some remote part of the country.

The new By-Laws make our Society a truly democratic organization, and the members of every Section throughout the country should take advantage of the opportunities thus given them to strengthen the standing of the profession in their community and thereby also benefit the parent body.

In these strenuous times the busy engineer has little time for reading, and I fear that Mr. Marburg's address will not receive anywhere near the publicity it deserves. I wish there was some way in which it could be brought to the attention of every member of our Society, and I would like to suggest that the Committee on Local Sections urge each Section to have a meeting in the near future where this address will be made a special feature and given more than the usual amount of publicity. To add to the interest of the meeting, I would suggest that a member of the Council be requested to present the address to the Section, instead of having it read by one of the local members. If something of this sort could be done, and this very important matter brought to the attention of the majority of our members, I believe the Increase of Membership Committee would find that there was no further use for its activities. Such a step would put our Society in such a position that there would be no question in the mind of any engineer as to which engineering society was the strongest and most influential. The only question would be which society stood next to the A.S.M.E. in the good it is doing to our country and to the profession in general.

I want to congratulate the Committee on Local Sections and the Council on the splendid work that they have done in the way of broadening the influence of our Society.

I. E. Moultrop.

Boston, Mass.

The Second Law of Thermodynamics

To the Editor:

As e pressed by Clausius[1] and Lord Kelvin,[2] the second law of thermodynamics has been generally understood to mean that work may not be obtained from the inherent heat of the atmosphere.

Although these statements apparently have been mathematically demonstrated, the mind nevertheless rebels against a law which denies the possibility of using any portion of the thousands of millions of horsepower existing at all times in the atmosphere. Such mental rebellion led the writer to attempt the utilization of this energy in spite of what is declared to be the second law of thermodynamics.

The result of this effort, which thus far has been imaginative rather than through mathematical treatment, seems to indicate several methods by which work may be realized from the heat in the air.

---

[1] "Heat cannot of itself pass from a colder to a hotter body."
—Clausius.

[2] "It is impossible, by means of inanimate material agency, to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of surrounding objects."—Kelvin.

A simple apparatus which demonstrates the fact has been constructed and operated by the writer and will be understood by referring to Fig. 1. This apparatus consists of but three essential elements, viz., the boiler 1, the turbine 2, and the condenser 3. A pipe connects the top of the boiler to the nozzle of the turbine and the casing of the turbine opens directly into the condenser. The condenser is provided with means for evaporating water from its outer surface. In the sketch this is shown as a fibrous covering 4, which keeps moist by drawing water from the receptacle 5 by its capillarity. A pipe connects the bottom of the condenser to the bottom of the boiler.

The operation will be most easily understood by assuming the plant completed and ready for starting. The first act is to exhaust the air from the entire system through the valve in the boiler. A quantity of liquefied gas sufficient to partly fill the boiler is next introduced through the same valve, which is then closed. Finally the receptacle at the bottom of the condenser is filled with water.

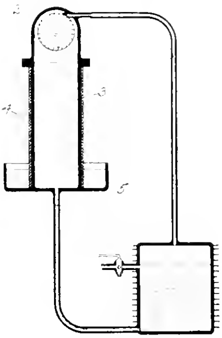

FIG. 1 APPARATUS FOR OBTAINING MECHANICAL WORK FROM THE HEAT IN THE AIR

The heat interchanges or cycles, of which there are two, commence as soon as evaporation of water takes place from the exterior of the condenser. The water, in the act of evaporating, removes an increment of heat from the condenser, causing a reduction in temperature and consequently a condensation of the vapor therein. This, in turn, brings about a difference in pressure between the condenser and the boiler which is available for operating the turbine. The condensate from the condenser enters the boiler at a temperature lower than that of the atmosphere, which enables the boiler to absorb an amount of heat from the atmosphere equivalent to the amount rejected by the condenser to the atmosphere less the amount converted into work. The difference of level between the liquid below the condenser and that in the boiler serves in place of a pump for feeding the boiler.

The little plant shown in Fig. 1 has been running continuously for some time, using sulphur dioxide as the working fluid. It will be seen that the capacity of the plant is a function of the relative humidity of the atmosphere, being greater in a dry climate than in one of more humid character. Operation would cease when the relative humidity reached 100 per cent, or when the temperature fell to 32 deg. fahr.

That the mechanism operates at all is due to the fact that nature, in the course of her unending processes, is continuously depositing moisture out of the air, rendering it again capable of absorption in the manner and with the result described. If we were compelled to remove the moisture content, no doubt the work cost would balance the work derived, but if nature does this work without cost to us, it would seem that, as far as our interests are concerned, mechanical work may actually be derived from the heat in the air. Furthermore, it appears that under these conditions and through the agency of evaporating water, heat does in fact pass from a cold body to a hotter medium, for the heat from the cold condenser is rejected to a hotter atmosphere.

If these conclusions are correct—and they must be, since the machine runs—then the statements of Clausius and Kelvin are not strictly true.

The efficiency of the cycle, based on the standard of Carnot, is low, but it may even be that the Carnot cycle itself is not the final word in heat efficiency.

The question as to commercial possibilities has been asked, and after a careful study of the matter the writer is convinced that no commercially successful results may be hoped for, although remarkable performances might be realized if no attention were paid to investment costs. The heat interchanges may be of interest to other members of the Society as they have been to me.

PERRY OKEY.

Columbus, Ohio.

REVISION OF BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code, and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in THE JOURNAL, with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes before the Rules are brought to the final form and presented to the Council for approval. This has been done, and the revisions were presented in the March issue of THE JOURNAL, pp. 234-247, in the April issue, p. 316, and in the May issue, pp. 398-400, in the form proposed for submission to the Council, except as they may be modified by editing without change of sense.

The revisions finally agreed on are those that have been published in the March, April and May issues of THE JOURNAL, with the modifications which follow. Although these modifications are in a sense final, the Committee would like any one who has an important criticism or suggestion to offer to submit the same immediately to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y.

MARCH JOURNAL, P. 235

PAR. 9:

IN THE THIRD LINE OF THE ADDED SENTENCE IN PAR. 9 AFTER THE WORD "IN," CHANGE "AND" TO "PROVIDED," AND IN

the fourth line replace the words "shall be" by "is."

Par. 19:

In the first line of Par. 19 after the word "straps" insert the words "for double strap joints."

March Journal, p. 236

Par. 167:

After the word "diameter" in the second line of Par. 167*a* insert the following:

Having a thickness less than 10 per cent of the outside diameter, provided the thickness does not exceed No. 6 B. W. G.

Change the last sentence of this paragraph to read as follows:

For other tubes the flange test is not required:

Boiler Code, Page 41

Par. 168. Change the first sentence of Par. 168 to read as follows:

168 *Flattening Tests.* A test specimen 3 in. in length shall stand flattening between two parallel plates until the distance between the plates is not over five times the wall thickness, without showing cracks or flaws.

March Journal, p. 236

Par. 169:

In the last part of the last sentence of Par. 169 replace the words "the blow to be equivalent to 2 lb. falling 2 ft." by the words "or the equivalent."

Boiler Code, Page 41

Par. 171. Change Par. 171 of the Boiler Code to read as follows:

171 *Number of Tests.* One of each of the physical tests specified shall be made from each of two tubes in each lot of 250 or less. Each tube shall be subjected to the hydrostatic test.

March Journal, p. 236

Par. 190:

In the fifth line of Par. 190 before the word "plate" insert the word "shell."

March Journal, p. 237

Par. 198:

In the third line of Par. 198 transfer the words "measured from the outside" to the second line after the word "depth."

Par. 199:

In the first line of Par. 199 after the word "stays" insert the following:

with heads not less than 1.3 times the diameter of the stays.

In the fourth line of this paragraph place a period after the word "plate" and eliminate the rest of the sentence.

Par. 200:

In the eighth line of Par. 200 change the word "or" to "of."

Par. 203:

In the fourth line of Par. 203*b* in place of the words "in Par. 199 which applies to" insert the word "for."

In the fourth line of Par. 203*d* omit the words "in Par. 199."

In the second line of Par. 203*e* change the word "of" to "or."

March Journal, p. 238

Par. 212:

Revise Par. 212*c* to read as follows:

c A cylindrical furnace which requires staying shall be stayed as a flat surface as indicated in Table 3, except that the pitch may be increased to p_1 as provided in the following formula:

$$p_1 = p\sqrt{\frac{PR}{PR - 250t}}$$

in which

p = maximum pitch measured between the centers of the staybolts in the longitudinal rows, and between the centers of the staybolts in circumferential rows, in.

P = maximum allowable working pressure, lb. per sq. in.

R = internal radius of furnace, in.

t = thickness of plate in *sixteenths* of an inch.

Fig. 12*a*:

Change the second section of lettering at the side of the cut, Fig. 12*a*, to read as follows:

Not less than $\frac{1}{2}t$ if $C = 150$ or less, and not less than t if $C = 175$.

Par. 214:

Change the side heading of Par. 214 to read as follows:

Areas of Heads to be Stayed.

Add at the end of Par. 214 the following:

In water tube boilers, the tubes of which are connected to drum heads, the area to be stayed shall be taken as the total area of the head less the area of an annular ring of width d measured from the inner circumference of the drum shell.

Par. 215:

In the first line of Par. 215 insert before the word "heads" the word "tube."

March Journal, p. 239

Par. 239:

Change the first sentence of the last paragraph of Par. 239 to read as follows:

Where an unstayed furnace has a riveted longitudinal joint, it may be of the lap type for inside diameters not exceeding 30 in., irrespective of the height or length of the furnace. For inside diameters not exceeding 36 in., a riveted longitudinal joint may be of the lap type, provided the furnace does not exceed 36 in. in height or length.

March Journal, p. 240

Par. 253:

In the seventh line of Par. 253 before the word "bolted" insert "firmly," and in the eighth line after the word "position" insert "by tack bolts." In the ninth line after the words "tack bolts" place a period and eliminate the rest of the sentence.

Fig. 17*a*:

Change the first word of the caption under Fig. 17*a* to read "Dimensions" instead of "Proportions."

Par. 256:

In the fourth line of Par. 256 after the word "bolts" insert the following:

to hold the plates firmly together.

In the last sentence of this paragraph omit the words "The tack bolts shall be not over 12 in. apart and" so that the sentence will begin with the words "A rivet."

Par. 257:

In the sixth line of Par. 257, capitalize the word "calking," to begin a new sentence.

Boiler Code, Page 66

Par. 261. In addition to the revision proposed in the March Journal for Par. 261, which appears on p. 240, make the following changes.

Change the two formulae under the first paragraph of Par. 261 in the Boiler Code to read as follows:

$$\text{For single ring: } W = \frac{(1 + 2nd)}{2t} t_1 + nd$$

$$\text{For double rings: } W = \frac{(1 + 2nd)}{4t} t_2 + nd$$

Below the formulae, in the list of definitions insert the following:

n = number of rows of rivets.

In the definition of "S" insert before the parenthesis the following:

in single or double shear.

March Journal, p. 240

Par. 268:

Change the last paragraph of Par. 268 to read as follows:

When the maximum allowable working pressure exceeds 100 lb. per sq. in., a connection riveted to the boiler to receive a flanged fitting shall be used for all pipe openings over 3 in. pipe size.

Par. 269:

In the third line of Par. 269 after the word "relieving" change the rest of the sentence to read as follows:

capacity of 2000 lb. per hour or less is required by the rules.

Par. 272:

Add a new sentence at the beginning of Par. 272 to read as follows:

272 Safety valves shall be of such a type that no failure of any part can obstruct the free and full discharge of steam from the valve.

March Journal, p. 241

Par. 273:

In the fourth line of Par. 273 in place of the word "riveted" insert the words "irremovably secured."

Par. 274:

Change the second sentence of Par. 274 to read as follows:

For all other types of power boilers, the minimum allowable relieving capacity shall be determined on the basis of 5 lb. of steam per hour per sq. ft. of boiler heating surface for boilers with maximum allowable working pressures above 100 lb., and on the basis of 3 lb. of steam per hour per sq. ft. of boiler heating surface for boilers with maximum allowable working pressures at or below 100 lb. per sq. in.

Par. 292:

In the first line of Section 3 of Par. 292 change the words "ball checks" to "check balls." In the fourth line of Section 3 change the words "ball check" to "check ball," and omit the word "valve." Also in the fourth line change the words "The annulus around the ball" to "The space around each ball." Omit the last sentence of this section.

Omit Section 4.

Renumber Section 5 to read Section 4, and in the second line of this section after the word "opening" insert the words "or otherwise arranged."

Renumber Section 6 to read Section 5.

Renumber Section 7 to read Section 6, and in place of the first sentence insert the following:

The balls must be accessible for inspection.

In the second sentence of Section 7 (renumbered Section 6), omit the word "also."

March Journal, p. 242

Par. 296:

In next to the last line of Par. 296 insert the word "the" before "exclusive."

March Journal, p. 243

Par. 345:

In the second line of Par. 345 before the word "washout" insert the word "sufficient," and after the word "holes" omit "for," and insert the following:

"or other openings to permit."

May Journal, p. 400

Par. 254:

Cancel the revision proposed in the May Journal and allow Par. 254b to remain as it appears in the March issue of The Journal, p. 243, so that the entire Par. 354 will read as it appears in the March Journal.

March Journal, p. 243

Table 9:

In the last line of the title of Table 9, change the word "of" to "for."

Par. 356:

Add a sentence to Par. 356 as follows:

A relief valve used on a hot-water heating boiler need not have a lifting device.

March Journal, p. 243 and May Journal, p. 400

Par. 361:

Change the next to the last sentence in Par. 361 to read as follows:

Pipe connections to gages less than 1 in. pipe size shall be of brass, copper or bronze composition.

March Journal, p. 244

Par. 374:

Cancel the revision of Par. 374, and make it read as it appears in the present edition of the Code.

Par. 392:

Cancel the revision of Par. 392, and make it read as it appears in the present edition of the Code, except that where "Table 8" is mentioned substitute "Table 16."

Par. 422:

After the formula in Par. 422 insert the following:

where

W = weight of steam generated per hour, lb.

C = total weight or volume burned per hour at time of maximum forcing, lb. or cu. ft.

H = heat of combustion of fuel, B.t.u. per lb. or per cu. ft. (see Par. 427).

The Pennsylvania State College, Engineering Experiment Station, has completed a reprint from the annual report of 1913-14, in which are set forth methods of purchasing coal by specification and of sampling coals for analyses. The subject is treated of by J. A. Moyer and J. B. Calderwood. The bulletin gives the methods of gathering coal samples as used by the Bureau of Mines, Interborough Rapid Transit Co., New York City, United States Steel Corporation, General Electric Co., and Detroit United Railways, and also methods of coal sampling and analyses of the American Chemical Society and of The American Society of Mechanical Engineers.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

During the last month the Secretary has, by his attendance at local meetings, carried both to the Sections and to the local societies the evidence of interest, and he has received the inspiration of those meetings. The most impressive thing is, that this war is making a people of many races and opinions—a nation with a common and not altogether selfish aim. These higher purposes and thoughts have not been suddenly evolved, quite the contrary. It needed but this crisis to bring them out. The master mind of President Wilson has expressed them and, lo, the conduct of the World War has changed!

It is peculiarly consistent with the ideals of the several groups of the engineering profession that they should have joint meetings, by virtue of the tremendous part they have in the prosecution of the war and that they should come together more intimately than ever, and that all should consecrate their endeavor on the altar of freedom.

In one of the local meetings I have just attended, an army officer stated that up to the last spurt of our troops, as I understood it, about the first of April, fifty per cent of the expeditionary forces were engineer troops.

The relation of the engineer to the war is vital. He has corresponding responsibilities. Our standing as a profession will be in proportion as we meet them. Self-sacrifice is the foundation of nobility.

To my horror, an editorial in the current number of an usually excellently edited technical paper pleads that "It becomes the duty of engineers in particular to combat the theory that normal construction activities must be curtailed because of the war."

Nothing could be more false. A simple e planation will suffice to convince everyone, and especially the engineer, that all activity not contributing to the conclusion of the war must be stopped.

Belgium, France, England and Canada are 100 per cent efficient. See to it that we are likewise.

The failure of the United States to live up to her production program, while caused by many contributing factors familiar to those who read the newspapers, yet is due fundamentally to the general lack of appreciation of each individual person in this country of the fact that it is necessary to cease "normal construction." Congress is making huge appropriations, but not much more than half last year's appropriations have been expended to date due to the "normal," "business as usual" demands interfering with Government requirements.

In England during the last twenty months not one pleasure car has been manufactured! Compare this with a recent statement in the newspapers that one prominent manufacturer in the United States had cut down his output to only one-third. As a general estimate, at the present time, only one-third of the labor of this country is engaged in war work.

In order to get out the production that the Congressional appropriations provide for, we must:

a Convert all our activities to war work

b Secure an increased output of each individual, either by increased rate of execution, or by longer hours, and

c Secure the labor of 10,000,000 more people—what is termed "dilution of labor" in England.

Failure of every individual man, woman, and child to accept the absolute cessation of all "normal construction" postpones that much the date of victory.

The one man, more than any other, who is teaching this lesson to the nation is an engineer, Herbert Hoover; and while he is putting the emphasis on food, nevertheless the principle applies to every activity of every individual and is going to influence the ability of this country to conclude this war.

When we are about to do anything or purchase anything, we should ask ourselves if we can do without it. If we can, then it is a non-essential. Obviously this applies to every one of our families, and to as many others as we can influence.

To sum up, we must unite our forces. "We must produce more *and* use less—not produce more *or* use less." The supreme effort must come from the American Nation. Let us, as engineers, lead.

Calvin W. Rice,
Secretary.

Council Notes

On the invitation of the Philadelphia Local Committee, the Council paid an enjoyable visit to Philadelphia on Tuesday, April 23. The program was announced in the last issue of The Journal, and all the features as arranged were successfully carried out. The following is an abstract of the business meeting which was held in the afternoon.

Abstract of Minutes

The following members were present at the Philadelphia meeting: Charles T. Main, *President;* Wm. H. Wiley, *Treasurer;* John A. Stevens, Spencer Miller, D. S. Jacobus, Ira N. Hollis, John Hunter, John H. Barr, Jesse M. Smith, C. H. Benjamin, W. F. M. Goss, Arthur M. Greene, Jr., C. T. Plunkett, D. Robert Yarnall, L. P. Alford, *Chairman Committee on Meetings;* L. C. Marburg, *Committee on Sections;* Henry Hess, *Chairman Standardization Committee*, and Calvin W. Rice, *Secretary.*

Honorary Vice-Presidents. The President reported the appointment of Honorary Vice-Presidents for the following several occasions:

> *National Industrial Conference Board*, Hotel Astor, New York, April 18, 1918, L. P. Alford, the President and the Secretary.
>
> *National Foreign Trade Council*, Cincinnati, April 18 to 20, 1918, E. A. Muller.
>
> *League to Enforce Peace*, Philadelphia, May 16 to 18, 1918, R. H. Fernald and D. Robert Yarnall.

Congratulations to Sir John A. F. Aspinall. The President reported that a letter of felicitation had been sent to Sir John A. F. Aspinall, Honorary Member of the Society, upon his

recent election as president of the Institution of Civil Engineers.

Belgian Industrial Mission. The President was instructed to extend the welcome of the Society to the Belgian Government Mission on Industrial Management about to arrive in this country to study our methods and apply them in the reconstruction of Belgium after the war. The Commission has since arrived and the Society has had opportunities to assist them in their work, and the Belgian Minister at Washington, His Excellency M. de Cartier, has expressed his thanks to the Society for its efforts.

Non-Essential Industries. In response to a request of the New York Local Committee, the President was asked to appoint a Committee on Readjustment of Industries for War Work to outline a plan in which the Society can best aid in readjusting the industries of the country to meet the needs of the war, and to report back.

Research Committee. The following sub-committees were discontinued and discharged with thanks: Clinkering of Coal, Materials of Electrical Engineering, and Safety Valves.

Boiler Code Committee. Boiler Code Interpretations in cases Nos. 187, 188 and 189 were approved with slight modification and ordered printed.

Electric Welding Council. On recommendation of the Boiler Code Committee, the following Sub-committee on Electric Welding was appointed to coöperate with and report to the Boiler Code Committee: F. L. Fairbanks, *Chairman;* F. J. Cole, J. A. Dixon, E. R. Fish, S. F. Jeter, N. W. Kellogg, William F. Kiesel, Henry Torrance.

Steel Roller Chains Committee. The progress report of the Committee, which is a joint committee with the Society of Automotive Engineers, was received and ordered printed.

Power Test Committee. The resignation of Mr. E. M. Herr from the Advisory Board of the Power Test Committee was received with regret, and Mr. Francis Hodgkinson was appointed in his stead.

Engineering Foundation. It was voted to approve the amendments to the By-laws of the United Engineering Society, providing for an increase in the number of the members of the Engineering Foundation Board, and fixing the dates of the regular meetings of the Board.

Anti-Efficiency Legislation. Letters from Mr. Henry R. Towne, past-president of the Society, and from the National Council of Industrial Defense called attention to "anti-efficiency" riders attached to appropriation bills now before Congress, which would exclude from all Government work time-study methods, bonus systems, etc. The President reported that the Engineering Council was alive to this situation, and it was voted to heartily approve any steps taken by them tending to prevent the enactment of such blighting legislation.

Letter from C. C. Worthington. A letter was read from Mr. C. C. Worthington, son of Henry R. Worthington, deceased founder of the Society, giving reminiscences of the Society and its formation.

Commission to Standardize Screw Threads. The Society having been notified of the prospective early passage of a bill to create such a commission (since passed the House, May 8), it was voted that Past-President Hartness be nominated to represent the Society on the Commission when authorized.

National Board of Fire Underwriters. In response to the invitation of the Board the President was authorized to appoint a Committee to coöperate with them in the standardization of fire hose threads.

Adjournment was taken to reconvene on May 17, 1918, in New York City.

CALVIN W. RICE,
Secretary.

The Spring Meeting is On!

By the time THE JOURNAL reaches many of our members, sessions of the Spring Meeting at Worcester will be in progress. The prospects for a well-attended and useful meeting are excellent, and it is expected that the discussion will draw out a great deal of information that will be of material benefit to the membership. A full report of the meeting will appear in the July number of THE JOURNAL, including an account of the business transactions, the discussion upon the various papers presented, and a summary of the topical discussion on the fuel situation, concerning which a great deal of interest has been manifested, showing that the engineers of the country appreciate the need for their services in bringing about more economical use of fuel during the next winter season.

The features of the meeting were fully described in the last issue, and are here summarized for the benefit of any who may wish to refer to them in this number of THE JOURNAL.

Date of Meeting, June 4 to 7.

Headquarters, Hotel Bancroft: Part of the sessions will be held at the Hotel and part at Worcester Polytechnic Institute.

Tuesday Evening, June 4

Meeting at Hotel Bancroft, with reception following at Worcester Art Museum.

Wednesday Morning, June 5

Business Meeting, at which several important reports will be presented.

Addresses on Industries of New England.

Luncheon at Polytechnic Institute.

Wednesday Afternoon

Papers contributed by the Local Sections of New England and the Providence Engineering Society.

General Session, at which technical papers will be presented.

Session relating to courses of instruction in Safety Engineering.

Special excursions have been arranged for the ladies, including Tea at the Tatnuck Country Club.

Wednesday Evening

General War Session, with addresses on the Procurement Program of the United States Government.

Evening to close with a social time on the roof garden of the Hotel.

Thursday Morning, June 6

Session for the discussion of general technical papers.

Fuel Economy Session.

Vocational Training Session.

Thursday Afternoon

Excursion to the Norton Company's plant to inspect the community houses of that company. Luncheon served.

Brief session on Housing for Workmen.

Thursday Evening

Dinner at the Worcester Country Club.

Friday, June 7

All-day excursion to Camp Devens, Lexington and Concord, going and returning by automobile.

FREDERICK REMSEN HUTTON

FREDERICK REMSEN HUTTON, Honorary Secretary, Past-President, and for twenty-three years Secretary of the Society, died suddenly from heart trouble on Tuesday morning, May 14, when leaving his residence in New York for an automobile trip to the country. Services were held at his home on the Friday following, attended by many personal friends.

Up to the time of his death he had appeared to be in excellent health, and only the afternoon before had been in the Society's rooms, so that his death came as a shock to his many friends, who had only so lately met him in the course of their every-day duties.

Professor Hutton was born in New York, May 28, 1853. After preparation in a private school in New York, he entered Columbia College, receiving the degree of A.B. in 1873. After graduation he entered the School of Mines, and was given its degree in 1876. A year later he was appointed instructor in mechanical engineering as an associate of the late Prof. W. P. Trowbridge. This was the first recognition which Columbia gave to the important relations of mechanical engineering to other engineering courses. He entered the faculty as adjunct professor in 1881 and became professor in 1890. Upon the death of Professor Trowbridge, in 1892, the chair of engineering which he had occupied was divided, and professorships in civil engineering and electrical engineering were added to the already existing professorships of mining and mechanical engineering. Professor Hutton was made the head of the mechanical engineering department, which he directed until July 1, 1907, when he resigned, and in appreciation of his valued services was elected professor emeritus.

At the time of Professor Hutton's election to the presidency of the Society, an excellent summary of his work at Columbia was prepared by Mr. Fred. J. Miller, editor of the *American Machinist,* and published in that journal, from which the following is taken:

> Perhaps his most significant achievement during these years of service has been the development of the great mechanical laboratories of the University, during the period from 1897 to 1900, just subsequent to the transfer of the institution from the downtown site to its present location on Morningside Heights. This equipment includes the Baldwin locomotive mounted upon its testing equipment, the triple-expansion Allis-Reynolds engine, which is a three-stage air compressor, and the hydraulic equipment of the Henry R. Worthington Laboratory. A conservative estimate of the value of this equipment as installed, is not far from $100,000.
>
> It has been the professor's belief that to make experiments in illustration or confirmation of engineering formulas on engines or machines of small size, is to introduce an error not only of degree, but of kind, and that therefore the units should be of sufficient size to guard against this difficulty; and, furthermore, to make research into new fields sufficiently near to the actual conditions of practice so as not to prove actually misleading when their results are applied. The air compressor has been, with him, a favorite form of laboratory apparatus by reason of its illustrating to the student the complete cycle of generated mechanical energy, its storage in compressed air, and the liberation of that energy in a motor having a cycle similar to that of the original steam cylinder. In no other educational institution are there any larger units than those which have been here gotten together.
>
> The professor is also an earnest exponent of such a method of conducting laboratory instruction as to compel the student to exercise his thinking faculties, not only in devising the experiments and connecting up the apparatus, but in the interpretation of the results. In his discussion of this subject he has referred to the more formal system of definite instruction to the students by the use of printed logs which can be used half automatically as failing to make men out of the raw material. The automatic or log method he has called the "cook-book" system.

Professor Hutton became Secretary of the Society in 1883, three years after its organization, which was a critical time in its history. The membership was less than 400, and there was great difficulty in meeting expenses from the small sum received for dues, so that initiation fees had been treated as available current income. The previous Secretary, Mr. Rae, had received no salary and the office rent had been provided by reason of his relations with Mr. Henry R. Worthington, one of the founder members.

Professor Hutton was then a young man of thirty, Junior Professor of Mechanical Engineering at Columbia University,

THE HOUSE AT 12 WEST THIRTY-FIRST STREET: THE SOCIETY'S HEADQUARTERS DURING 16 YEARS OF PROFESSOR HUTTON'S SECRETARYSHIP

and able to arrange to give part time to the management of the Society in connection with his duties as a teacher. He was appointed Secretary in March at a salary of $1000 per annum. The Worthington office was given up and for a time the headquarters were in Professor Hutton's study at Columbia University; but it was soon found desirable to have a downtown office, and he rented at his own expense a room in what was known as the Smith Building, at 15 Cortlandt Street, and engaged an assistant whose salary he also paid. Professor Hutton states in his History that: "The location was chosen for its nearness to the ferry and approaches through Cortlandt and Liberty Streets, which were then the downtown entrances to the city from New Jersey and Pennsylvania. The

stock of volumes and extra stationery were taken to Columbia University and stored in a dark room available only for such uses. The office furniture of that modest undertaking was a Keuffel and Esser drawing table, some camp chairs and a specially designed stationery holder, somewhat along the lines of the revolving bookcases. There was no typewriter in use for more than a year. Later a bookcase made of pine, with certain locked-up cupboards, was added to receive the periodicals and exchanges."

From that time on, through the wise management and strong personality of the new Secretary, supported by the staunch founder members, who were the backbone of the organization in the early days, the Society grew and prospered consistently year by year, and one by one its many problems and difficulties were overcome. In this regard Professor Hutton displayed the same broad vision of future possibilities that so characterized Professor Thurston, who was the first President. This viewpoint was strongly emphasized by Professor Thurston's presidential addresses, which are recorded in the TRANSACTIONS.

In 1890, the house at 12 West Thirty-first Street was purchased for $60,000. This had been occupied by the Academy of Medicine, now located on Forty third Street, and was admirably adapted for a Society, but its acquirement was an ambitious project for a society without funds. The financing was left to a committee, of which J. F. Holloway, Stephen W. Baldwin and Professor Hutton were members.

Bonds were taken up by the membership to the amount of $32,000. A few of the older and wealthier members became guarantors to make good any deficiency should the Society be unable to meet its obligations, but they were never called upon, and the Academy of Medicine took a mortgage of $33,000. Five thousand dollars of the amount raised was used for alterations and furnishings.

It was this home where Professor Hutton became so closely identified with the work of the Society and formed so many pleasant associations with the members who came to the meetings or dropped in for a social time. The wisdom of acquiring the property was shown when it was sold in 1906 for $120,000, realizing a profit of nearly $60,000, and providing a fund which was a most helpful factor in procuring property for the new Engineering Societies Building, the gift of Mr. Carnegie.

With regard to the house on Thirty-first Street, Professor Hutton has written:

"It is perhaps difficult at this day and with the present strength, standing and income of the Society to realize what an enormous step and undertaking the purchase and responsibility for that house were to the modest men of that day. If it had failed, the consequences to the Society would have been most disastrous. Its success was the greatest thing that ever happened to it up to that time and for many years."

AUDITORIUM AND LIBRARY OF THE HEADQUARTERS AT THIRTY-FIRST STREET, SO CLOSELY ASSOCIATED WITH PROFESSOR HUTTON IN THE MINDS OF MANY OLDER MEMBERS

Professor Hutton's first meeting as Secretary was the Cleveland meeting in 1883, where the papers were for the first time distributed in advance by means of galley proofs, with the cuts printed on separate sheets. From time to time other events occurred which for some special reason were particularly notable. Among these was the trip to Europe in 1889, which had a wide influence in giving international recognition to the Society and establishing the bond of professional fellowship between this and the countries visited. Another was the Chicago Meeting of 1893, at the time of the Engineering Congress held during the Columbian Exposition.

Gradually the Society outgrew its quarters on Thirty-first Street, and after sixteen prosperous years moved to the splendid Engineering Societies Building, which it now occupies jointly with the other engineering societies. Professor Hutton was a member of the Joint Conference and Building Committee appointed to carry out the generous intention of Mr. Andrew Carnegie to provide a necessary building for the use of the several societies and a building for the Engineers' Club, and

to plan the proposed structures. He was also Secretary of the Building Committee, and later Secretary of the United Engineering Society. From the fact that the Civil Engineers decided to remain in their own building and the Mining and the Electrical Engineers had no buildings of their own, a great many meetings of the Committee, of which a total of seventy-four were held, besides numberless conferences, took place in the house of the Mechanical Engineers on Thirty-first Street, and during the construction much of the accounting and other business was transacted there.

Professor Hutton was one of the Board of Trustees of the United Engineering Society, which is the holding corporation for the building.

At the end of twenty-three years' service and coincident with the removal to the new building, Professor Hutton resigned his position as Secretary. He felt that the time had come when the Society needed the full time and energies of a secretary, and should not be compelled to share these with the engineering department of a university. It seemed proper that the retiring secretary, who had led the Society from the modest beginnings where he paid the office rent out of his own pocket up through the successive stages of development, to the point where it constituted a prime element in a great engineering headquarters for the whole country, should be elected to the presidency. He was made President for the year 1906-1907, and officiated in that capacity for the first time at the Indianapolis Meeting in 1907. At the end of his term he took for his presidential address the subject of the Mechanical Engineer and the Functions of the Engineering Society.

In 1908 he was elected Honorary Secretary, under the constitutional provisions which created such an office, a distinction which he held until his death.

With his varied and complex duties at Columbia University and in the secretary's office of the Society, it was impossible that he should enter largely into literary productions, but, nevertheless, he was the author of several books and several papers presented to the Society. The earliest of these was an elaborate monograph on Machine Tools for the Census of 1880. At that time technical books were few and engineering periodicals were fewer, and this treatise on machine tools stood out as one of the important documents of the time, and was used by engineering schools for the instruction of their students.

He wrote two textbooks, on Mechanical Engineering of Power Plants and on the Gas Engine. A distinctive and valuable feature of the former was the summarizing of the advantages and disadvantages of the various types and combinations of apparatus used in power plants. He was editor for encyclopedias and dictionaries, notably the Century, of 1911.

Fortunately for the Society, Professor Hutton was prevailed upon to write its history, which was issued by the Society in a handsome illustrated volume in 1915. While the volume is in no sense biographical of any one individual, and refers to Professor Hutton by name in only a few instances, it must, nevertheless, be regarded as largely a history of his own endeavors and accomplishments, and will long remain a valued and cherished volume to many of his friends and fellow-members. Special attention should be called to the chapter on Some Principles of Society Philosophy, which embodies a remarkably comprehensive statement of the stages of development of a great engineering society and the principles underlying them.

In 1911 Professor Hutton served as consulting engineer to the Department of Water, Gas and Electricity, New York City, and from 1905 to 1911 was vice-chairman of the Museum of Safety. He was consulting engineer to the Automobile Club of America and chairman of its Technical Committee from 1912, in which capacity he supervised the important testing work conducted by the club in its laboratory. He was one of the first engineers to use an automobile and to enter into a study of automobile construction.

In many ways since serving as President, Professor Hutton has been active in Society affairs, particularly as a member of the Committee on Constitution and By-Laws. In this work he endeavored to meet in a broad and progressive spirit the new conditions which were imposed upon the Society by its growth and expansion into various fields of activity and the establishment of its many Sections. He had, as always, a clear vision of the future and laid his plans accordingly. He was also a member of the John Fritz Medal Board of Award. His interest in young men was evidenced by his service on the Student Branch Committee of the Society. He has often presided at meetings and represented the Society on special occasions, which he always did with a distinction and grace of manner peculiarly his own. Here, as on all occasions, his felicity of expression and ready wit, his cordiality and withal his dignity, were strong characteristics.

In 1882 Columbia conferred upon him the degree of Ph.D. and in 1904 the degree of Sc.D., which is the highest distinction which the University places upon one for scientific and engineering training.

Professor Hutton is survived by Mrs. Hutton, who has so often been present with him at the Society's social functions; and two sons, Dr. Lefferts Hutton, now regimental surgeon in the army, with rank of Major, and Mancius S. Hutton.

The following are letters of appreciation received from friends of Professor Hutton, members of the Society.

LETTERS OF APPRECIATION

There was no one, in my estimation, who contributed more to the successful upbuilding of the Society than did Professor Hutton. He was absolutely untiring in his efforts, and even when he had gone to the mountains for his well-deserved summer rest, he kept the interests of the Society before him, and was of the greatest assistance in its work.

Professor Hutton's services as Chairman of the Committee on Constitution and By-Laws showed the greatest interest and devotion. These documents, under which we are at present acting, are evidences of his handiwork and wise judgment in almost every line.

There is much more I could say, but as there will be plenty of testimony from others I will only add that the Society showed its appreciation of his efforts in its behalf by conferring upon him all the honors within its gift. The history of its early struggles, which Professor Hutton wrote personally, remains as a monument to his memory; and indeed it would be hard to look into the archives of the Society without finding some evidence of his work.

WM. H. WILEY.

In the death of Frederick R. Hutton, we have lost one who has most worthily represented the Society in its ideals, traditions and active work.

During all of the years of service as Secretary, President, and Honorary Secretary, he was unremitting in his efforts to have the activities of the Society maintained on a high plane, both among its own membership and their relations to the public.

It was always he who was called upon to represent the Society on special occasions, which he did with such rare grace and wonderful expression.

He has always seemed to be an integral part of the Society. We shall all miss him, particularly those who have been associated with him these many years.

CHARLES T. MAIN.

The American Society of Mechanical Engineers in parting with Frederick Remsen Hutton loses one of its best beloved, highly respected and most valuable members.

No man has done more than he in guiding and keeping the

Society to its high ideals. In the earlier years he, with other high-minded engineers, set the standards of these ideals. He was ever watchful that they be not lost to view.

His devoted and willing services to the Society as Secretary, President, Member of Council, in many committees and notably in the Committee on Constitution and By-Laws, have left their indelible imprint on the history of the Society.

The Society will long remember and greatly miss his wise counsel, his genial manner and gentlemanly bearing, always fair and considerate.

May his influence still remain with us.

JESSE M. SMITH.

We who for years have been active in the A.S.M.E. heard with profound sorrow of the death of Dr. Hutton, for many years the efficient Secretary of our Society and then President and Honorary Secretary.

The Society owes a real debt of gratitude to Dr. Hutton for his services so effectively and tactfully rendered to the Society and the cause of engineering in general.

ALEX. C. HUMPHREYS.

All of us who knew him well can but deeply mourn the untimely death of our genial friend, Professor Hutton. Leaving to others an expression of appreciation of his work as a teacher, a research worker, a writer and one of the most successful of secretaries of a great engineering society, I will speak of his kindly spirit, his gracious manner and his attainments and accomplishments, in music, in oratory and in other lines of social and domestic life. His talk and his work, moreover, were spiced with a vein of humor which made him a delightful companion. All of this personal equipment doubtless tended toward the success of his earnest life work in connection with the many branches in which he was so ardently engaged.

OBERLIN SMITH.

Those of us who know something of the situation in 1883, when Professor Hutton became Secretary of The American Society of Mechanical Engineers, realize just what his work meant to us and what it will continue to mean so long as the Society exists.

Called to assume charge of its affairs at a time when its finances were inadequate to its expenses, when its publications were in arrears, when its membership was small and scarcely increasing, when its future lay in the balance, he gave to its recuperation an effective energy which never slackened for more than twenty years, and which, more than any other thing made the Society what it is today.

In those days Professor Hutton *was* the Society, for the able men who stood back of him could give but a small portion of their time to its affairs, while he stood before the membership as the one man who knew them all, greeted them all, welcomed them all, whose presence put life into otherwise dreary meetings, and whose judgment and untiring effort finally put the Society in a position where he could relinquish its guidance to others with a position so fully assured that failure had become impossible.

HENRY HARRISON SUPLEE.

The sudden death of our old-time friend and Honorary Secretary of the Society, Professor Hutton, is indeed sad news, and while I cannot at this moment do more than to express my sorrow and sympathy in this loss, to his family, to the Society and to his many personal friends, by so sudden a termination of his active life, and to state how greatly we shall all miss his ready and well-chosen words when voicing the feeling and sentiments of the members of the Society at meetings, as Secretary and as President, or at our many functions, abroad as in 1889, or in this country.

The results of the work he did in building up the prestige of the Society during its earlier years, and for many years since, while he was Secretary, are manifest in the position which the Society now holds in the broad field of engineering.

His uniform courtesy and cheerfulness under many trying conditions, will also be gratefully remembered by all whose good fortune it has been to know him personally. I certainly feel that in his death is the loss of a friend.

GEO. M. BOND.

I am confident that all the members of the A.S.M.E., from the time when Professor Hutton first became Secretary, have pleasant and delightful memories of him as our secretary and friend. His excellent and expert use of the English language was a continual example to those of us who made so many mistakes in our use of the mother tongue, and I believe we all use better language from having heard him speak. As an example, one item of his literary work is shown in the resolutions given by our Society to our British cousins following the acceptance of the invitation of the British Society in 1910.[2] Professor Hutton's keen sense of humor always kept us in good spirits. I remember on the occasion of our Annual Meeting in 1898 in the old society house on 31st Street, when I was sitting beside him, one of the largest members began to get up to discuss a subject then before the Society and I whispered to Professor Hutton, "He will now tell us what he did twenty-five years ago." The member began his remarks—"In 1872," and Professor Hutton instantly turned to me and said, "You're wrong, it's twenty-six."

The pleasant and delightful memories of Professor Hutton would fill a large volume and I wish those interesting episodes in his life which made us all happier were published. We all mourn his death and we all will cherish his memory.

WORCESTER R. WARNER.

Professor Hutton's sudden death is a great shock to me, particularly because when I saw him last, which was during the December, 1917, meeting of the Society, in New York, he appeared to be in splendid health, and full of his usual energy and spirit.

I know that the older members of the Society fully realize and thoroughly appreciate how much of the Society's present prosperity and high standard is due to Professor Hutton's devoted service during the long term of years which he served as its Secretary. I, as President of the Society, enjoyed greater opportunities of knowing, and thus appreciating, not only his work, but the loyal spirit and unselfish devotion to his duties, and also his wonderful tact and patience in meeting the many trying conditions which so constantly occurred.

The Society has passed through several strenuous periods, to emerge from each one stronger and more useful to its membership, and therefore to the whole engineering profession. One such period occurred during my presidency in 1891, when it became evident that its rapidly increasing growth, not only in membership, but also in the field of the Society's activities, and consequent usefulness, made a greater revenue imperative; therefore the question of lessening its activities and thus restricting the benefits to be derived from membership in it, or augmenting its income through increased dues, became a vital one. While the situation would seem to have been a plain one, the views of the membership were not at all alike—all earnest in their desire for the Society's good, but differing as to the proper ways and means. Secretary Hutton's position was a trying one, and only a man possessing his courage and certainty of being above just reproach, joined with never-ending patience and willingness to acknowledge the right of others to hold views differing widely from his own, could have met the situation in so successful a manner as he did.

ROBERT W. HUNT.

I have no doubt whatever that the entire Society shares with the Council a deep regret over Professor Hutton's death. His connection with the foundation of our Society and his long service to the Society and the individual members, have given us all a deep sense of gratitude for his effective work in putting the science of mechanical engineering upon a professional basis. I consider that his most important contribution. I feel a strong personal loss through a long acquaintance with him as a teacher at Columbia. He ought to stand to us all as the finest type of teacher, servant of the public, gentleman and scholar.

IRA N. HOLLIS.

Dr. Hutton's death removes a familiar and beloved personality from the activities of the Society. To those of us who had enjoyed the privilege of his friendship from the early days of the Society it counts as a personal bereavement.

For many years his work as Secretary made him the outstanding feature in the Society. Presidents and councillors had their day and passed on, often unknown personally to the majority of the members, but he remained, known to almost every member. He was admirably fitted for the work by his ability and engineering knowledge, but above all by his social qualities. His wonderful memory and sympathetic interest were a powerful aid in keeping up the membership in our days of adolescence and struggle. Nor

[2] Trans., vol. 32, 1910, p. 626.

did they lose their charm in more recent times when he had, with advancing years, reduced his activity but not his interest; his position as Honorary Secretary affording large opportunity for their exercise.

Other tributes will undoubtedly speak of his broad culture, his great felicity of expression, and his active detailed work for more than a score of years in caring for the interests of the Society and establishing the tone of the TRANSACTIONS at a high level. To those of us, however, who attach great importance to the human side, it will always seem that his greatest work was in the promotion of acquaintance and good feeling among the members, thereby assuring a steady growth in numbers and in *esprit de corps*. It is, perhaps, not going too far to say that the Society is his monument.

W. M. McFarland.

In the passing from earth of Professor Hutton I have lost a warm personal friend, The American Society of Mechanical Engineers has lost one of its devoted and untiring members, the engineering profession a distinguished representative and the country one of its best and most able citizens.

I have known Professor Hutton ever since the Cleveland Meeting in 1883, the first that he attended as Secretary. At that meeting he showed those qualities that have meant so much to the Society in the quarter of a century during which he was Secretary. Both in this country and in foreign countries we have always been proud of the part he has taken in representing the Society and the engineering profession, and in these later years as Honorary Secretary he has ever been ready to devote his time and thought to the problems of the Society. Among the many important services he rendered was the writing of the valuable history which we now possess, and in the great progress that has been made in recent years in coördinating the various branches of the engineering profession he has always been most helpful and sympathetic.

His life was one of service to his fellow men and in the highest sense he was a noble Christian gentleman.

Ambrose Swasey.

My acquaintance with Professor Hutton began with my membership in the Society. His efficiency as the Society's Secretary early made an impression upon me which the passage of years and the riper acquaintance incident thereto have not impaired. He was masterful in presenting the business of a meeting: in voice and manner, in skill and courtesy, he was altogether charming and his presence made significant proceedings which without him would have passed without notice. His theories concerning the conduct of Society affairs were based upon broad conceptions and generous procedures. Probably few of our younger members appreciate the extent to which in the early days Professor Hutton contributed to the Society's upbuilding.

W. F. M. Goss.

Through the death of Professor Hutton the Society has lost one of the grand Old Guard who founded and brought it to its present position and power. Always working with its welfare at heart, the Society will be forever a living monument to his endeavors. His cheerfulness and fair-mindedness overcame many an obstacle that might have led to disaster in less tactful hands. He will be remembered with honor by all and by his most intimate friends as a scientist who nurtured the flower of faith, a truly Christian gentleman.

D. S. Jacobus.

The following telegrams were received:

My belief, based on thirty-five years' membership in our Society, is that Professor Hutton, by his delightful personality, alert sympathy, remarkable memory of men's faces, and kindly greetings to all, no less than by his engineering knowledge, contributed tenfold more than any other one man to the success of our great Society in the formative period of its first twenty years. I deeply mourn his loss.

John R. Freeman.

Professor Hutton still lives. The prestige of the Society resulting from his twenty-five years of effort as Secretary was the foundation for the Society's further scope and usefulness. As an influential officer of one founder society and Secretary of the United Engineering Society during its formative period, Professor Hutton therefore contributed in a large way to the enhancement of the engineering profession in America.

Calvin W. Rice.

In the passing away of Professor Hutton The American Society of Mechanical Engineers has lost not only one of its honored members; not only one of the first authorities in the science of engineering; and not only one whose work and personal influence will undoubtedly be considered by future historians of the Society as most potent in molding the character of the Society toward these highest standards to which it will ever be faithful, but it has lost one of its most beloved and esteemed members, and one who was ever radiant with that cordiality and inspiration so essential in the building of a society. It leaves an example to the remaining members, especially the younger and more active members, of the noblesse and great value of Professor Hutton's characteristics to the success of the Society and the country that it represents and serves.

James Hartness.

One of the saddest messages received in many years was the announcement of the passing away of our past President and associate, Professor Hutton. I have been a guest at his fireside and always made welcome there. Our Society owes much of its high standing to our good friend who has gone from among us and his memory will always be cherished by its members.

John A. Brashear.

Classification of Trade Personnel

A work of almost incalculable value in classifying trades has been completed for the War Department by John J. Swan, Mem.Am.Soc.M.E., of the Trade Test Division of the Committee on Classification of Personnel in the Army. It is known as War Department Document aid in classifying skilled men who may be drafted or enlisted into the National Army, so that the right men can be selected for any required occupation in connection with the technical departments of the army.

There are 565 classifications, each of which is defined both as to the duties to be performed and the qualifications of a well-trained, high-grade man or journeyman (this is sometimes an expert or a foreman) who can do the work required. The classification also gives the nearest equivalent or substitute occupations which can be drawn from in case it is necessary to secure an additional supply of any particular kind of labor.

This is probably the first elaborate vocational analysis which has been published. The system has been taken up by the U. S. Department of Labor, and is being used first of all to cover the munitions industries, but later will be applied to all trades and industries. It has also been adopted by a large number of manufacturing firms. Only those who have attempted such a task can appreciate the amount of work involved in compiling so large a mass of material.

Submarine Engineer Officers Wanted

The Navy is in need of professional engineers for submarine duty, not over 35 years old and physically strong. The qualifications include citizenship in the United States, the degree of mechanical, electrical or mining engineer from a university of recognized technical standing, and at least two and one-half years' practical engineering experience. The candidates selected will be commissioned Ensign in the U. S. Naval Reserve Force, and will be sent to the Naval Academy and to the Submarine School in New London for a special technical course.

Engineers subject to the Selective Draft Law and those now in the Army are eligible. Letters from at least three responsible personal acquaintances must accompany each application. Address the American Engineering Service of the Engineering Council, Room 903, 29 West 39th St., New York City. Early responses are requested.

Tribute to John Porterfield Sparrow

At a recent meeting of the Committee on Flanges and Pipe Fittings of which the late John Porterfield Sparrow was chairman at the time of his death and whose obituary notice was published on page 328 of The Journal for April, the following tribute was paid to his memory:

John Porterfield Sparrow, Chief Engineer of the New York Edison Company, a member of the American Society of Mechanical Engineers and Chairman of its Committee on Flanges and Pipe Fittings, died March 18, 1918.

Mr. Sparrow was one of the best-known mechanical engineers in the United States, particularly in the modern power-station field.

His deep study into the intricate details of his work have brought forth improvements and economy in the power plant field of inestimable benefit to mankind.

His patience, courtesy, sterling honesty and ripened judgment were sources of pleasure to all who came in contact with him.

His death is a severe loss to this Committee, which can only be filled by the softening influence of time.

Great Canadian Reflecting Telescope

Every member of the Society feels a personal pride in the successive scientific attainments of "Uncle John" A. Brashear, who became endeared to so many during the year of his presidency. A few have known of the suspense under which he has been laboring in the difficult task of grinding and polishing the glass for the great Canadian Reflecting Telescope; and all should now know of his happiness and relief at the successful completion of this undertaking. Not only is the glass finished, but it has safely arrived at the Canadian observatory at Victoria, B. C. In a letter, Dr. Brashear writes: "The glass reached its destination in less than six days after I bid it good-bye on the car in Pittsburgh, a trip of 2200 miles. You bet Uncle John and his son-in-law and some others are happy over this 'news,' after three years and eight months." The following article from a Pittsburgh paper gives some interesting facts:

This precious glass, which took nearly four years in the grinding, polishing and correction of its accurate parabolic surface, required great care in packing and shipping, the glass disk alone weighing 2¼ tons, and in its iron cell nearly three tons; the packing case weighed not far from a ton.

The order for the big disk of glass was given to the St. Gobain glass works in France, but it was cast in their factories at Charleroi in Belgium, sent to Antwerp, placed on the ship, the *Vaterland*, and left Antwerp just a week before Germany declared war.

The first grinding of the glass required over two months. This was done to get it into shape for the finer grinding and polishing. About four hundred pounds of glass were removed from the upper and lower surfaces and the edges, leaving the dimensions as follows: Diameter, 73 in.; thickness, 12 in.; opening in center, 10⅛ in. in diameter; curvature, a radius of 60 ft.; the focal length of the telescope used in the Newtonian form, 30 ft.; in the Cassegrain form, about 108 ft.

After this preliminary work on the great glass, it was taken to the basement of the workshop, where the temperature conditions could be kept constant, and where the great tube with its double walls had been constructed on which all the final tests were made. Here Mr. McDowell took entire charge of the polishing and correction of the parabolic front surface, having as his right-hand assistant, Mr. Fred Hageman.

After polishing for a few hours with a large polisher, the glass had to be lifted into the testing tube, and an interval of at least 10 hours had to be allowed before the effect of the polishing could be studied, because of the disturbance of the surface by the heat produced in the polishing process.

As the surface came nearer and nearer to the true figure, smaller polishers were used over zones standing up, possibly one-hundred thousandth of an inch or less. This is what is called local polishing and is always done by handwork. Sometimes the local work lasted for only 15 to 20 minutes, then the huge glass had to be lifted into the testing tube to wait until the surface worked upon came to the normal temperature of the entire mass of glass. Patience as well as consummate skill is an imperative factor in this delicate work.

After over three years of delicate working, waiting and testing, by methods of marvelous accuracy, Dr. Plaskett, the astronomer of the Dominion of Canada, pronounced the parabolic curve almost twice as good as the specifications called for. The error allowed, which is practically beyond the limiting error that can be detected when used in the telescope, is one two hundred and fifty thousandth of an inch, while the greatest error that could be found in the surface was one four-hundred thousandth of an inch and in some parts of the surface not over one-millionth of an inch. In using some of the smaller polishers, not over one five millionth of an inch from any one part of the surface was removed.

Many people think only of the magnifying power of a telescope, but this is an erroneous idea. Its greatest value is as a collector of light from, let us say, some distant star cluster, and as this glass is over 4000 in. in area, it will gather and concentrate 100,000 times more light from the distant star than the human eye.

The mounting has been erected for some months at the Victorian Observatory and is a wonderful model of the highest efficiency in modern mechanism, made by the Warner and Swasey Company, Cleveland. The instrument complete weighs fifty-five tons, and the great reinforced cement piers supporting the axes weigh about 500 tons. The moving parts, with the great mirror, weigh about thirty-five tons, and these moving parts are all handled and controlled by electric current. Indeed, so delicately is the great telescope, with its massive parts, moved to follow a star or any heavenly body that the power required to light a 16-cp. electric lamp does the work.

The Victoria Observatory is situated about eight miles from the city, in one of the most beautiful sites on the Pacific coast. It was selected after many studies as to the best condition for astronomical research in Canada, the question of minimum change of temperature and minimum cloudiness being important factors in the selection of the site.

First American-Built "Tank"

The clipping which follows relates to the army tank *America*, of which papers throughout the country have published illustrations during the past month. It is one of the largest and heaviest tanks which has yet been constructed, weighing 45 tons. It is a steam, oil-burning tank, and the same size as those now used in Europe—35 ft. long and 11½ ft. wide.

Prof. E. F. Miller, Mem.Am.Soc.M.E., head of the Mechanical Engineering Department at the Massachusetts Institute of Technology, designed the huge war machine, in which it is said the *Brittania*, the British tank which recently visited Boston, could be stored without the least trouble. The construction work was done under the direction of Col. Francis R. Shunk, department engineer of the Northeastern Department. Major Henry Adams, Engineers Corps, N. A., assistant department engineer, was in executive charge of the work. Capt. Albert S. Smith, Superintendent of Buildings and Power at the Institute, was chief construction engineer. The construction work was done in the stockade in the rear of the Institute, where machine shops have been installed.

The American army engineers took full advantage of the experiences of the English engineers and improved upon the British type in many ways, eliminating features and designs which were proving impracticable in the big war engines of Europe and adding many distinctive American engineering improvements, so that the *America* stands out as a peer of all war engines and a monument to American ability and ingenuity.

The plans for the new American tank are now available for use in other factories where the Government is turning out tanks and engines, and the *America* is but premier of a great fleet.

The American "tank" service has started a drive in Boston for recruits between eighteen and forty-five, whether registrants under the selective service law or not. The tank corps, which has opened its office at 3 Tremont Row, is one of the newest and most attractive parts of Uncle Sam's fighting machine, and is one of the few open to men above the draft age. (*The Tech*, April 20, 1918.)

The John A. Stevens Trust Fund

It is fitting, now that the details of arrangement have been completed, that announcement should be made of the establishment of the John A. Stevens Trust Fund through the generosity of Mr. John A. Stevens, a member of the Council of the Society and Chairman of the Boiler Code Committee.

The fund consists of a $15,000 insurance policy which Mr. Stevens has taken out with the Connecticut Mutual Life Insurance Co., Hartford, Conn., and which will eventually be turned over to the Society. The net annual income accruing from this fund will then be allotted annually in equal shares to the person or persons who have that year invented or been responsible for an invention of noteworthy progress in the art of engineering having to do with the conservation of fuels in the generation of light, heat and power. If there should be no special processes evolved during any particular year, the net annual income is to revert to the person creating or being responsible for any engineering safeguard having to do with the protection of life and property.

Mr. Stevens has become widely known among our members and throughout the country as chairman of the A.S.M.E. Boiler Code Committee, a position which he has held since the inception of the committee in 1911. He had previously been a member of the Massachusetts Board of Boiler Rules, and this experience, combined with his varied practical experiences in the steam-engineering field, both marine and stationary, splendidly equipped him for the new standardization work, the most important by far which our Society has attempted.

Since 1909 Mr. Stevens has been in private consulting practice at Lowell, Mass., during which time he has superintended the construction of many power plants, made analyses of several large properties, and introduced a number of innovations in the line of power engineering. For 13 years previous he was chief engineer of the Merrimac Manufacturing Company, Lowell, Mass., where he practically rebuilt the entire steam installation, and also superintended the power work of the company's southern mills. This connection gave Mr. Stevens an intimate acquaintance with every phase of New England mill practice, and the large steam and power plants and distribution systems so important in this great industry.

The basic work of his life, however, was accomplished on shipboard, beginning when a young boy with the arduous duties of a fireman on a lake dredge, and closing in 1896 as a junior first assistant engineer on the transatlantic liner *St. Paul*. While engaged in marine work he served as engineer on several of the largest boats both on the Great Lakes and on the Atlantic Ocean, and it was characteristic of him that he lost no opportunity to acquire an intimate knowledge of marine practice, even though at a sacrifice in salary; for example, when first assistant engineer of the steamship *Illinois*, sailing between Philadelphia and Antwerp, he changed to the position of fifth engineer of the *New York* in order to become acquainted with the machinery of this larger and more modern vessel.

Besides serving as fireman on the lake dredge when a boy, he managed to complete a full machinist's apprenticeship in a shop doing a wide variety of construction and repair work, and later worked as journeyman. He recounts how, having reached this point, his mother prevailed upon him to complete his education, and how he took a full high-school course and a year at the University of Michigan. Finding, however, that mathematics was not his forte, he resolved that he would rather be a "first-class man in an engine room," where he had already met with success, than a "second-class man in a designing room." Therefore, securing a leave of absence from the university, he enlisted as second engineer on one of the lake steamers, a branch of the profession which he followed closely until he became connected with the Merrimac Company at Lowell. At the age of twenty-seven he secured an ocean steamship's unlimited license.

The trust fund which Mr. Stevens has established is in recognition of the opportunities for acquiring experience and for promoting the welfare of the engineer and his work which he has always found to exist in the engineering field; and as an incentive to the young engineer to develop further the field of light, heat and power with which he himself has been for so long identified.

John A. Stevens

Award of Medal by Cotton Manufacturers' Association

In 1898 the board of government of the New England Cotton Manufacturers' Association established the Association Medal, which was to be awarded to any person whose work would be of sufficient importance to the purposes for which the organization was devoted, including any papers read before the Association, the production of any mechanism or processes in the fabrication, design or finishing of cotton goods, comprising mill construction, the generation of power and its distribution, or any of the works tributary to cotton manufacture.

At the joint meeting of the American Cotton Manufacturers' Association and the National Association of Cotton Manufacturers held in New York, May 1 to 3, a medal was presented to Mr. Stevens for his paper on the Evolution of the Steam Turbine in the Textile Industry, which had been given at the annual meeting of the National Association of Cotton Manufacturers held in Boston, Mass., April 25 to 26, 1917. This paper was one of exceptional interest and value, in that it outlined with striking forcefulness the advantages of the steam turbine as it has been lately developed, for use in the power plants of textile mills. The author referred in detail in his analysis to the various economic developments in turbine design, embracing the low-pressure, mixed-pressure and extraction turbines, which features have undoubtedly been potent in

bringing this form of prime mover into more general use in mills where low-pressure steam is required in various processes. The paper also placed on record some most interesting and valuable information concerning the use of geared turbines for direct driving of mills, in the adaption of which the author and his associates have had much experience. It concluded with a description of a water-tube boiler of immense size which was developed by Mr. Stevens conjointly with Arthur D. Pratt, Mem.Am.Soc.M.E., which, it is predicted, would have effected a marked advance in large power-plant methods had it not been for the setback to industrial development resulting from the war. This boiler was described and illustrated in The Journal for July 1917.

In making the award, therefore, the Association states that it is "not only for contributing the most to the advantage of the cotton industry during the year, but for large conservation of coal and men made by the people using his services during the past years."

The obverse of the medal bears the names of the Association and the dates of its foundation and incorporation. In the middle is a loom of the pattern in general use at the time of its foundation, and this loom is surrounded by a garland of cotton bolls. The name of the Association in mural text is girted by a polygon of hanks of yarn knotted together.

The reverse side bears a chaplet of oak and laurel leaves, symbolizing strength and honor, and secured at the base by an American eagle with outstretched wings, the whole forming a frame for the tablet containing the inscription.

Cullom Medal for Dr. F. H. Newell

To Dr. Frederick H. Newell, Mem.Am.Soc.M.E., the American Geographical Society has awarded the Cullom Geographical Medal. This gold medal has been given from time to time to explorers, writers and men who have contributed in important ways to the advancement of geographical knowledge. The last recipient of the medal was General George W. Goethals, in recognition of his services in connection with the Panama Canal. Others who have been honored by the receipt of this medal are Admiral Robert E. Peary, Fritdjof Nansen, Sir John Murray, the Duke of the Abruzzi, Sven Hedin, and Sir Ernest H. Shackleton, every one of international and cosmopolitan reputation.

Professor Newell's accomplishment is perhaps best expressed by the inscription on the medal, which reads:

Frederick Haynes Newell

Organizer and Director
of the
United States Reclamation Service
1907-1914

He carried water
from a mountain wilderness
to turn the waste places
of the desert
into homes for freemen.

Pennsylvania can claim Professor Newell, but during his studies both at grade schools and the Massachusetts Institute of Technology, as well as at other times, he has been closely identified with Boston and its institutions. His work at the Institute was in mining engineering, with post-graduate studies, for his doctor's degree in geology and hydraulics. Three years after graduation he became an assistant in the U. S. Geological Survey and shortly afterward was given for his special work the study of the irrigation of arid lands. From a division of the U. S. Geological Survey the specialty was developed into a separate service, the Irrigation Service, of which Professor Newell was made director by President Roosevelt in 1902. Till 1914 he remained director of this service, the engineering works of which are of highest rank. He outlined and developed the splendid plans of the Reclamation Service with its great dams, basins and waterways. In May 1915 he was appointed by the University of Illinois head of the department of Civil Engineering.

Presentation of the Edison Medal to Col. John J. Carty

Dr. John J. Carty, colonel in the United States Army Signal Corps, chief engineer of the American Telephone and Telegraph Company and past-president of the American Institute of Electrical Engineers, has been awarded the Edison Medal in recognition of his services in developing the science and art of telephone engineering.

The medal was presented on Friday evening, May 17, at the annual meeting of the American Institute of Electrical Engineers in the Engineering Societies Building in West 39th Street, New York. After a statement of the history and significance of the medal by Dr. A. E. Kennelly, Chairman of the Institute's 1917 Edison Medal Committee, Dr. Michael I. Pupin, of Columbia University, told of the work of Colonel Carty which has made him preëminent in the field of telephone engineering. The medal was then presented by the President of the Institute, E. W. Rice, Jr., also president of the General Electric Company.

The Edison gold medal was founded in 1904 by the Edison Medal Association, an organization composed of old associates and friends of Thomas A. Edison. It has been awarded annually since 1905 by a committee of 24 members of the American Institute of Electrical Engineers, the recipients in order being Elihu Thomson, Frank J. Sprague, George Westinghouse, William Stanley, Charles F. Brush, Alexander Graham Bell and Nikola Tesla.

Colonel Carty is well known as the engineer of the great transcontinental telephone line, and as the engineer who made possible wireless telephoning over distances up to 5000 miles. Since 1916 he has coöperated with the Signal Corps of the Army and with the various departments of the Navy in making arrangements which would insure the readiness of the great telephone system of his company for military service in case the United States became involved in the world war. Last year saw these plans put into active use with a marvelous degree of success. He is now giving much of his time to the development of the nation's Signal Corps work in this country and abroad.

Library Service Bureau

As the knowledge of the facilities of the Engineering Societies Library to serve members of the engineering societies and the engineering profession outside of New York—and sometimes in New York—through its Library Service Bureau increases, the requests for such service correspondingly increase. From January 1 to March 31 of this year the Bureau conducted 135 searches; 32 of these were made in mechanical engineering, 29 in mining and metallurgy, 21 in civil engineering, 18 in chemical engineering, 10 in electrical engineering, and 25 miscellaneous. The Library also made 24 translations in the same period, and supplied 615 photostatic prints.

AMONG THE LOCAL SECTIONS

During the past month Mr. Calvin W. Rice, National Secretary of the Society, and Mr. Ernest Hartford, Secretary of the Committee on Sections of the Society, visited a number of the Sections where meetings were held. Many of these meetings were well attended and much enthusiasm was evoked. All presented a patriotic atmosphere, and everywhere the enormous part played by the engineers in winning the war was the dominant feature.

At Meriden, Conn., where a paper was presented on the Browning machine gun, over 175 were present; at Bridgeport over 200 attended and at Boston over 400 gathered. The Detroit meeting developed action regarding the development of intensive courses for training women at technical colleges and schools, so that they may serve as draftsmen and tracers, or as inspectors in munitions and industrial plants.

At New York the vital question of labor turnover was taken up in a way that emphasized the opportunity of the engineer to take a leading part in the solution of this vital problem. Engineers are the connecting link between labor and capital in the large majority of the industries of the country, and it is hoped other Sections will follow the lead of New York in arranging meetings on this subject.

In addition to attending Section meetings at Indianapolis, Cincinnati, New Orleans, Chicago and Toronto, and a joint meeting at Birmingham of the Atlanta and Birmingham Sections, Mr. Rice attended meetings of engineers at Toledo, Dayton and Duluth. He found everywhere throughout the West and South that the engineers and people generally were thoroughly alive to their responsibilities, and the consensus of opinion was that meetings of engineering organizations were of great value in maintaining a proper morale and in building up an *esprit de corps* in the profession.

The Providence Engineering Society and Its President

In The Journal for March 1918 was published a group of portraits of the chairmen of the Local Sections of the American Society of Mechanical Engineers for the year 1918, through whose leadership the full value of membership in a great national organization is being realized to a greater extent than ever before. In this connection it is appropriate to refer to the affiliated society of the A.S.M.E., the Providence Engineering Society, and to publish a portrait of its president.

This society was organized in 1894 under the name of the Rhode Island Association of Mechanicians. The next year the name was changed to the Providence Association of Mechanical Engineers, under which name it continued until 1915, when it was reorganized to include all branches of engineering and became the Providence Engineering Society.

In 1911, when the Providence Engineering Society became affiliated with our own organization, it was known as the Providence Association of Mechanical Engineers. Its activities then pertained almost exclusively to the field of mechanical engineering, which is so strongly represented in the industries of Providence. Although it has remained in every way an independent organization in distinction from that of the several Sections of our Society, which are integral parts of the parent body, the affiliation represents a mutual interest between the organizations of a real and vital character. One pleasant feature of the affiliation has been the joint dinners held with officers of the A.S.M.E. as guests of the Providence society.

It is expected that a large number of the members of the Providence Engineering Society will attend the Worcester meeting during the first week of June, and the Providence organization has generously contributed to the success of this meeting by arranging for three professional papers from its own membership.

Robert Winthrop Adams, the president of the Providence Engineering Society, is a graduate of Worcester Polytechnic Institute in the electrical engineering course, and has been connected with the B. F. Sturtevant Company, Hyde Park, Mass., the D & W Fuse Co., Providence, R. I., the Pittsfield Works of the General Electric Company, and is now manager of the Providence office of the General Electric Company. When with the D & W Fuse Co. he was engaged in research and development work on enclosed fuses for three years, and during this period was awarded the degree of Electrical Engineer by the Worcester Polytechnic Institute in recognition of original research work.

Mr. Adams is the inventor of the transmission-line calculator

R. W. Adams, President of the Providence Engineering Society

for the rapid calculation of line drop in alternating-current circuits, and has been a contributor to various technical journals. As a member of the Rhode Island Council of Defense since its formation, he has had charge of all engineering matters in connection with preparedness and war work, including a complete war census of Rhode Island engineers.

Section Meetings

Birmingham

April 25. After a business meeting an interesting address was given by James W. Moore, of the American Cast Iron Pipe Company, on The Producer-Gas Plant of The American Cast Iron Pipe Company, and it was pointed out how coke braize was used instead of coal. Comparisons were made between coke-braize gas and gas from Pocahontas coal in a double-zone producer, and operating conditions and costs were traced.

W. L. RouECHE,
Section Secretary.

Boston

April 30. A joint meeting of the Boston Society of Civil Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers was held at the City Club. Over 400 engineers sat down to supper.

Mr. W. H. Blood, Jr., of the American International Shipbuilding Corporation, delivered a very interesting illustrated address on Hog Island, the greatest shipyard in the world. By word and picture he described the wonderful progress which was made in six months in the transformation of a barren waste into a seething hive of industry, embodying an area of over 900 acres with a working force averaging over 26,000 persons.

Mr. Alfred D. Flinn, Secretary of the Engineering Council, gave a talk on the progress and aims of the Engineering Council.

Short addresses on subjects of the day were given by Major-General H. F. Hodges, in command of Camp Devens, at Ayer, Mass., and Mayor Andrew J. Peters of Boston. Motion pictures were shown illustrating the adaptability of a new rudder which has been perfected by Mr. H. O. Westendarp of the General Electric Company. By skilful manipulation the pilot can by means of this new type of rudder make a vessel go forward or backward, or circle right or left without changing the direction or speed of his engine. This should prove a wonderful aid in combating the U-boat.

W. C. Starkweather,
Section Secretary.

BUFFALO

April 24. An instructive lecture on Ball Bearings, Their Designs, Manufacture and Application, was given by S. W. Gurney, of the Gurney Ball Bearing Co., Jamestown, N. Y., who is a recognized authority on this subject.

May 1. The meeting was of a strictly business nature and included the reports of officers and committees and the election of officers for the Engineering Society of Buffalo for the coming year. The following were elected: George B. Bassett, president; H. P. Parrock, vice-president; E. B. Neil, secretary, and W. M. Dollar, treasurer. Messrs. F. A. Lidbury and David W. Sowers were elected directors.

E. B. Neil,
Section Secretary.

CHICAGO

April 22. At a joint meeting of the Chicago A.S.M.E. and A.I.E.E. Sections and the mechanical and electrical sections of the Western Society of Engineers, C. F. Kettering, Mem.Am.Soc.M.E., delivered a talk on The Automobile Power Plant.

May 24. Mr. John E. Ericson, Mem.Am.Soc.M.E., and City Engineer, delivered a lecture on The Mayfair Pumping Station.

Arthur L. Rice,
Section Secretary.

CONNECTICUT SECTION

Bridgeport Branch

April 24. Motion pictures, a good dinner and some fine speeches on matters of interest to engineers and factory men were the features of the spring meeting, held at the Stratfield Hotel. Members and friends from all parts of Connecticut were present at this meeting, 211 being the total number attending the evening gathering.

Committee and "get-acquainted" meetings were held during the afternoon. Ten reels of motion pictures, most of them being illustrative of factory work, were shown, and later dinner was served.

The opening address of the meeting was made by Henry B. Sargent. Secretary Rice, the second speaker, told of some of the work of the Society. Judge John S. Pullman gave a patriotic address, telling of the work of the draft and how men could best serve their country by their jobs. Clinton E. Woods, of the Woods-Keller Company, spoke on Factory Accounting as a Bill for Controlling Production. Harry E. Harris, Chairman of the Joint Gage Committee of the A.S.M.E. and S.A.E., discussed Facilitation of War Production by Practicable Manufacturing Allowances. He was followed by William R. Webster, vice-president of the Bridgeport Brass Company, whose subject was Intelligence, Specifications and Inspection as a Factor in Production Increases. Allen B. Lincoln, associate director of the U. S. Department of Labor of the Connecticut State Council of Defense, told of the work of his department.

E. L. Fletcher,
Branch Secretary.

Hartford Branch

May 13. After a brief business meeting, at which the following officers for the year 1918-19 were elected: Chas. S. Blake, chairman, Frank E. Howard, vice-chairman, and M. D. Church, secretary-treasurer, an interesting talk on submarines was given by P. B. Brill, general manager, Lake Torpedo Boat Company. He cited the progress of battleship design, giving a general idea of the various types of vessels and the arrangement of their guns, and described the various protective devices from torpedoes. A description of the different types of submarines from the earliest designs down to the most advanced stage of the art was given.

Private Wm. J. O'Neill, of the 101st Machine Gun Battalion, who has just returned from the fighting line in France, gave a short talk on the importance of the people at home supporting the soldier in the trenches. Some of his own experiences in the trenches were touched on.

S. F. Jeter,
Branch Secretary.

New Haven Branch

May 10. A business meeting preceded the regular meeting of the Branch at which the following officers were elected for the year 1918-19: E. H. Lockwood, J. Arnold Norcross, F. L. Mackintosh, Edwin Pugsley, A. C. Jewett and S. H. Barnum, 2d.

Professor Breckenridge then reported on the plan of the Fuel Administration to inspect all power plants of the country. In conformity with this plan a state fuel engineer will be appointed for Connecticut. It was then voted that the Executive Committee of the Connecticut Section coöperate with the proposed plan by nominating a suitable candidate for this position, reporting same to the Fuel Administrator.

An informal paper was given on the Development of the Repeating Rifle by Edwin Pugsley, Jun.Am.Soc.M.E. The talk was illustrated by a striking display of rifles showing the steps of the development leading up to the repeating rifle and including the Browning gun.

E. H. Lockwood,
Branch Secretary.

CINCINNATI

May 11. In a very inspiring address Secretary Rice presented the various activities of the A.S.M.E. He pointed out how the opportunity and ability of its members to serve in numerous ways has enabled the Society to be of substantial service to the Nation in solving problems such as those relating to the conservation of coal, wages of employees, the draft law, nitrate plants, and the activities of the Research Council. The policy of helping to win the war is exemplified in the appointing and organizing of committees, the presentation of papers and the use of the Society's rooms as recruiting offices. The Roll of Honor now constitutes 15 per cent of the membership. The whole sentiment expressed in the dedication of the Engineers' Club House at Dayton, Ohio, represents the spirit of the times in which engineers are realizing their duties toward the communities in which they live and are acquiring a feeling of civic responsibility. Such a sentiment, created through the Sections, will enhance the status and solidarity of the engineering profession. Mr. Rice suggested that the Sections organize committees on pavements, water, etc., and sub-committees of chemical, civil, electrical and other branches of engineering.

At present there is an opportunity to assist in the training of mechanics for the service. One million men are needed and at present there is provision for only ninety thousand by the first of September. Each member of the Section was then called upon to pledge his support in assisting in the war education work in Cincinnati.

Mr. Fred A. Geier, Assoc.Am.Soc.M.E., made a short address in which he emphasized the importance of the problems with which the Council is confronted at this time, and the policy in dealing with matters of national interest.

John T. Faig,
Section Secretary.

DETROIT

May 3. The Detroit A.S.M.E. Section held its Annual Meeting in conjunction with the Detroit Engineering Society at the Board of Commerce Building.

After the dinner, the election of the Executive Committee for 1918-19 was held and the following officers were elected: E. C. Fisher, E. J. Frost, F. H. Mason, E. J. Burdick and J. C. McCabe.

Mr. Robert H. Kuss, Mem.Am.Soc.M.E., and Consulting Engineer of Chicago, presented a very interesting paper on Coal Con-

servation, discussing that part of this broad subject embraced within the handling at the power house, furnace construction, firing methods and control.

Dean M. E. Cooley and Secretary F. H. Mason presented the following set of resolutions:

WHEREAS, The demands of the country for men and means to fight the war have resulted in a deficiency of skilled workers in the trades and professions; and

WHEREAS, The women of this country could with a short period of training fit themselves to fill these positions, as women have done in other countries at war; and

WHEREAS, Among the things which women could do advantageously are *drafting* and *tracing, inspection and testing of materials, both physically and chemically*; therefore, be it

RESOLVED, That the universities, colleges and technical schools throughout the land be asked to consider the question of meeting this demand by providing special courses of instruction open to women students qualified to pursue such courses; and further, be it

RESOLVED, That employers who could use such skilled help exert their influence with their universities, colleges and technical schools, and coöperate with them in developing and making available a great body of intelligent and adaptable women who are as eager and willing to serve their country as their brothers;

THEREBY bringing about not only increased effectiveness in fighting the war, but also a greater mutual respect and saner relationship of our men and women.

These resolutions were unanimously adopted, and it is hoped all members of the Society will give wide publicity to them in order that some definite results may be promptly obtained in the training of women to fill subordinate positions in the drafting room and inspection departments of the industries.

F. H. MASON,
Section Secretary.

INDIANAPOLIS

May 10. The officers elected for the ensuing year are as follows: L. W. Wallace, chairman; W. A. Hanley, vice-chairman; B. G. Mering, treasurer; F. C. Wagner and G. A. Young.

Secretary Rice gave an address on the relation of the National Society to the Section, the relation of the engineer to the war, and ways in which he can assist the National Fuel Administrator and his city or community.

The subject Heat Losses in Uncovered Steam Pipes was also discussed.

W. A. HANLEY,
Section Secretary.

MILWAUKEE

March 13. Under the auspices of the A.I.E.E. Section, Professor Cyril M. Jansky, of the University of Wisconsin, delivered an interesting lecture on Science in War, bringing out the part that science plays in the affairs of men. A very interesting film was shown entitled The King of the Rails, which pictured the electrical division of the C. M. & St. Paul R.R.

April 10. At a meeting held under the auspices of the American Society of Refrigerating Engineers, Mr. Charles L. Fortier, chief engineer of the Johnson Service Company, gave an illustrated talk on Automatic Control Apparatus for Temperature Control in general and also as applied to the refrigerating industry.

May 8. A lecture on The White Coals of Wisconsin, in which a very complete description of the Wissota Dam was given, was delivered by N. J. Whelan, industrial commissioner of the Wisconsin-Minnesota Light & Power Co., and V. S. Hillyer, construction engineer with the same company.

FRED H. DORNER,
Section Secretary.

NEW ORLEANS

May 13. Under the auspices of the Louisiana Engineering Society and the A.S.M.E. Section a meeting was held at which the Honorable T. F. Carlisle, British Consul, delivered a very interesting address on Britain and the War the Last Twelve Months.

Secretary Rice gave a talk on the War Activities of the A.S.M.E. and the Need of Coöperation Among Engineering Societies.

A business meeting followed at which the following officers were elected for 1918-19: H. L. Hutson, chairman; E. W. Carr, secretary; R. T. Burwell, W. B. Moses and J. S. Barelli.

H. L. HUTSON,
Section Secretary.

NEW YORK

May 21. Labor Turnover was the subject of the meeting and was discussed by the following speakers representing makers of ships, aeroplanes, ordnance and machine tools: L. D. Burlingame, industrial superintendent, Brown & Sharpe Mfg. Co., John Calder, Aeromarine Plane & Motor Co., Capt. Boyd Fisher, Ordnance Department, U. S. A., Dudley Kennedy, American International Shipbuilding Corp., H. E. Miles, Council National Defense, J. J. Pearson, British War Office, H. F. J. Porter, consulting industrial engineer, and Orrin W. Sanderson, director of labor, B. F. Goodrich Company.

Opportunity was given to participate in short three-minute speeches and among the discussers were the following: F. H. Colvin, Editor *American Machinist*; L. P. Alford, Editor *Industrial Management*, and Eric Oberg, Editor *Machinery*.

A more detailed account of the meeting will appear in the July JOURNAL.

W. HERMAN GREUL,
Section Secretary.

ONTARIO

April 18. A very interesting paper on the Heat Treatment of Low-Carbon Steels was presented by W. M. Wilkie of the Steel Department of the Imperial Munitions Board. The discussion that followed the paper bore principally on the troubles encountered by the producers and users of shell steel. Among the engineers present were a number of those connected with local munitions plants, and their remarks based on actual experiences and the solution of various troubles under war time conditions were very interesting.

CHESTER B. HAMILTON, JR.,
Section Secretary.

PHILADELPHIA

April 23. The Philadelphia Section entertained the Council of the National Society at a dinner meeting at the Adelphia Hotel at which over one hundred members of the Section were present.

During the preceding day, the Council had visited and inspected Cramp's Ship Yard, and also the Hog Island plant of The American International Shipbuilding Corporation.

Mr. Lewis F. Moody presided at the meeting. He introduced as toastmaster D. Robt. Yarnall, chairman of the National Committee on Sections. The Council was given a greeting from Philadelphia by W. S. Catell. President Chas. T. Main responded in behalf of the Council. Following President Main, Messrs. James Hartness, C. C. Thomas, S. M. Vauclain and W. C. L. Eglin each gave a short talk.

J. P. MUDD,
Section Secretary.

PROVIDENCE

April 24. Under the auspices of the Municipal Engineering Section an illustrated lecture was delivered by Frank E. Winsor, chief engineer of the Providence Water Supply Board on The Development of the New Providence Water Supply.

April 25. A business meeting of the Efficiency Section was held, at which new officers were elected.

April 30. At a joint meeting of the Rhode Island Section of the American Chemical Society and the Providence Engineering Society, Lieut.-Col. Allerton S. Cushman, Ord. Dept. U.S.N.A., delivered an illustrated lecture on The Manufacture of Military Primers. Mr. H. Anthony Dyer also delivered a short address in connection with the unfurling of the service flag of the society.

May 8. Prof. L. B. McMillan, of the H. W. Johns-Manville Co., gave an address on Thermal Insulation at the Power Section meeting.

May 14. At the Machine Shop Section meeting a discussion on Experimental Investigation of Machine Tools and Its Effect on Machine Tool Design was led by Professor James A. Hall, of Brown University, a number of representatives from various machine-tool companies contributing toward the discussion.

JAMES A. HALL,
Correspondent.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by June 15 in order to appear in the July issue.

CHANGES OF POSITION

Albert H. Hudson, formerly general purchasing agent of the Wright-Martin Aircraft Corporation, New York, has assumed the duties of purchasing agent of the American International Steel Corporation, New York.

John D. Bowles has left the employ of the Springfield Gas and Electric Company and Springfield Traction Company, to become associated with the Douglas Company, of Cedar Rapids, Iowa, in the capacity of general mechanical superintendent.

William G. Edmondson has resigned from the Illinois Zinc Company, Peru, Ill., to reënter the service of the Interstate Commerce Commission, as mechanical engineer, with headquarters at Washington, D. C.

Francis L. Lindemuth, formerly affiliated with the H. Koppers Company, Pittsburgh, Pa., has become associated with Perin and Marshall, consulting engineers of New York.

Charles E. Burgoon has severed his connection with the Sandusky Cement Company, Cleveland, Ohio, and has accepted a position in the engineering department of the Air Nitrates Corporation, New York.

Jacob H. Wallace, formerly engineer with the Western Chemical Manufacturing Company, Denver, Colo., has become associated with the United Verde Copper Company, Clarkdale, Ariz.

A. E. Howard, formerly production engineer for Ingersoll-Rand Company, Phillipsburg, N. J., has accepted a similar position with Manning, Maxwell and Moore, and will be located at the Ashcroft plant, Bridgeport, Conn., for the next two months.

Charles D. Reeve has resigned his position as vice-president and factory manager of the Grand Rapids Brass Company, Grand Rapids, Mich. He has bought a controlling interest in the American Brass Novelty Company, of Grand Haven, Mich., and holds the position of president and general manager with the company.

John Chucan has left the employ of the International Harvester Corporation, Tractor Works, Chicago, Ill., to assume the position of mechanical engineer with the Goodwin Car and Manufacturing Company, Inc., of the same city.

Jonathan A. Wilson, until recently traveling engineer for the Babcock and Wilcox Company, Bayonne, N. J., has accepted the position of purchasing agent for the Todd Shipyards Corporation, of New York.

E. R. Kenner, formerly with the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., is now with the Air Nitrates Corporation, Muscle Shoals, Ala.

A. C. V. Malm, formerly president and general manager of the Malm Machine Company, Dayton, Ohio, has assumed similar duties with the Malm Engineering Company, of Philadelphia, Pa., a newly formed company. In addition to consulting engineering, the new company has leased the rights to manufacture the Malm rotary punch presses for rubber and metal punching, now patented, belonging to the Malm Machine Company.

John J. Eason has accepted the position of works manager with the United States and Cuban Allied Works Engineering Corporation, operating the Havana Iron Works and the Havana Dry Dock Company, in Cuba. Mr. Eason was formerly connected with the Havana Marine Railways, Inc., Havana, Cuba, in the capacity of general superintendent.

George E. Barrett, until recently affiliated with the Sprague Electric Works, Bloomfield, N. J., has assumed the duties of inspector of naval construction, Bureau of Construction and Repair, Washington, D. C.

Otto G. Jenner has severed his connection as industrial engineer with the Inland Steel Company, Chicago Heights, Ill., and has accepted the position of superintendent with the Wilson and Bennett Manufacturing Company, Chicago, Ill.

John H. Nelson has resigned from the Bureau of Standards, Washington, D. C., to become research engineer with the Wyman-Gordon Company, Worcester, Mass.

Frederick G. Kenyon, formerly with the engineering department of Remington Arms Union Metallic Cartridge Company, Bridgeport, Conn., has become associated with the American Can Company, Liberty Ordnance Plant, of the same city, as chief draftsman.

Robert W. Ellingham has resigned from The Bilton Machine Tool Company, Bridgeport, Conn., to enter the employ of the Heald Machine Company, as works manager.

Harry G. Baldwin has resigned his position with the S K F Bearing Company, Hartford, Conn., to accept the position of assistant general manager with the Henry G. Thompson and Son Company.

ANNOUNCEMENTS

George F. Swain, of the Massachusetts Institute of Technology staff, has returned to the Institute from the western part of the country after having been honored twice by the University of California on the occasion of its semi-centennial, which conferred on him the degree of LL.D. and also accorded him the distinction of being the first engineer to deliver before the University one of the Hitchcock lectures, which are supported by an endowment of $10,000. For his subject, Professor Swain selected Some General Principles and Disputed Points in the Valuation of Public Utility Corporations.

James A. Beaubien has assumed the duties of general manager and mechanical engineer with the Weber Subterranean Pump Company, of New York.

Ernest B. Bishop has been transferred from the Ilion Works to the Smith Premier Works of the Remington Typewriter Company, Syracuse, N. Y.

William R. Wilson, until recently secretary of the Alberger Pump and Condenser Company, New York, has been elected vice-president, and Richard C. Williams has been elected secretary of the company.

Schuyler S. Wheeler, of Ampere, N. J., is in France and later will go to Great Britain to explain the system that he has successfully used in his factories by means of which persons physically handicapped may become self-supporting workers. He was invited by Eugene Brieux, who is in charge of this sort of work done by the French Government.

Warren E. Murray, consulting engineer, announces the establishment of general engineering offices at San Francisco, Cal. He was, until recently, with the Western Sugar Refining Company, of the same city, as refinery manager.

Hal R. Stafford, mechanical engineer of the Economy Devices Corporation, New York, is now chief engineer of the Franklin Railway Supply Company, Inc., a consolidation of the Economy Devices Corporation and the Franklin Railway Supply Company.

Ralph G. Macy, formerly in the Army, and with the Air Reduction Company prior to that, has resigned his commission and is now with the New York Steam Company, New York.

The honorary degree of doctor of engineering has been conferred upon **Alexander C. Humphreys**, president of Stevens Institute of Technology, by the Rensselaer Polytechnic Institute.

Russell G. Clark, general draftsman of the American Thread Company, formerly at Willimantic, Conn., is now located at the head office of the company, in New York.

Hubert C. Verhey, who joined the technical department of the Emergency Fleet Corporation at Washington, D. C., in the capacity of chief draftsman is now at the head of the marine Diesel engine department.

R. S. Brunner has become identified with the Hamilton-Otto Coke Company, of Hamilton, Ohio.

F. G. Pease has become associated with the National Research Council, Washington, D. C., as chief draftsman of the Engineering Section.

Dugald C. Jackson, in charge of the Department of Electrical Engineering at Massachusetts Institute of Technology, Cambridge, Mass., has been called into active service. Last December Professor Jackson took the formal oath and now has been ordered "over there." His commission is that of Major in the Engineer Reserve Corps.

John T. Faig, for 12 years professor of mechanical engineering, University of Cincinnati, has been appointed president of the Ohio Mechanics Institute. Professor Faig will give special attention to training students in the operation and construction of internal-combustion engines.

Marcus T. Lothrop has been appointed assistant factory manager of the Timken Roller Bearing Company, Canton, Ohio. He has been metallurgist and has had charge of the steel and tube department of the company for the past seven years.

Captain Frederick H. Moody, who upon being wounded in France was evacuated to England, was temporarily loaned to the Ministry of Munitions for inspectional and expediting work on mechanical plants for the Air Board, is still acting as an Air Board officer.

APPOINTMENTS

Allen E. Ostrander has been appointed general mechanical engineer of the American Car and Foundry Company, New York. He was previously connected with the company in the capacity of mechanical engineer.

O. S. Maple, formerly purchasing assistant of the U. S. Shipping Board, Emergency Fleet Corporation, at Washington, D. C., has recently been appointed assistant purchasing officer.

Harold G. Kniese has accepted an appointment as mechanical draftsman and designer in the Nitrate Division, War Ordnance Department, Washington, D. C.

William D. Halsey has been appointed mechanical engineer with the National Advisory Committee for Aeronautics at Washington, D. C. He will continue his late afternoon and evening classes at the George Washington University, Washington, D. C., as assistant professor of mechanical engineering.

AUTHORS OF PAPERS, ETC.

Sterling H. Bunnell has contributed a brief article on Commercial Relations of Allies with Russia, to the May 16 issue of *The Iron Age*.

Harrison R. Cady is the author of an article entitled Electrification of Pumping Stations Saves Coal and Money which appears in the May 9 number of *Engineering News-Record*.

NECROLOGY

REAR ADMIRAL JOHN D. FORD

John D. Ford, Rear Admiral (retired) in the United States Navy, died at his home in Baltimore on April 8, 1918.

Admiral Ford was born on May 19, 1840, in Maryland and was educated in the public schools of Baltimore. He was graduated from the Maryland Institute School of Design in June 1861, receiving the Peabody Prize. The following year he was graduated from the Potts School of Mechanical Engineering and immediately entered the United States Navy as third assistant engineer. Early in 1864 he was made second assistant engineer and two years

John D. Ford

later became first assistant engineer. On December 27, 1890, he was made chief engineer.

During the Civil War Admiral Ford took part in the recapture of Baton Rouge, La., in March 1863, and in the Battle of Mobile Bay, 1864, and was on the *Arizona* when it was destroyed by fire off Poverty Point in the Mississippi River in 1865. He was wrecked in the *Sacramento* on the Coromandel coast of India in 1867.

In 1884 he was put on detached service for the purpose of establishing the Baltimore Manual Training School. From 1894 to 1896 he was connected with the Maryland Agricultural and Mechanical College. He was next assigned to the U. S. S. *Brooklyn*, with the relative rank of commodore, and in 1898 to the U. S. S. *Baltimore* (flagship), later becoming fleet engineer of the Pacific Station. He joined the Asiatic fleet and took part in actions of April 30, May 1 and August 13, 1898, and in the destruction of the Spanish fleet off Cavite, the destruction of the batteries at Cavite and at Sangley Point, the capture of the forts at Corregidor and the capture of Manila. On May 19, 1905, he retired from the service as Rear Admiral.

Admiral Ford was a member of the Associated Veterans of Farragut's Fleet, the Loyal Legion, the Society of Manila Bay, and of the American Society of Naval Engineers. He became a member of our Society in 1884.

HENRY ARTHUR BAYFIELD

Henry A. Bayfield was born in Charlottetown, Prince Edward Island, Canada, on June 19, 1873. He was graduated from McGill University, Montreal, in 1896, with the degree of Bachelor of Applied Science, having taken the mechanical-engineering course.

The first two years after his graduation he spent at the shops of the Intercolonial Railway, Moncton, N. B., as machinist and junior mechanical draftsman, and in testing locomotives on the road. He was also a year in the Great Northern Railway shops at St. Paul, Minn., where he was draftsman in charge of the office; later he was made superintendent of the company's shops at West Superior, Wis. For a short period he was with the Dar-

danelle Mining Company, Sa[illegible] B. C., overhauling and operating their plant. From 1899 to 1900 he was connected with the Albion Iron Works and Victoria Machinery Depot, Victoria, B. C., as a designer of small marine engines, boilers, etc., leaving this firm to become senior designer on dredging and hoisting machinery, air compressors, shop appliances, etc., with the James Cooper Mfg. Co., Montreal. In 1901 Mr. Bayfield was appointed mechanical superintendent in charge of dredging fleet, shops and shipyard for the Harbor Commissioners of Montreal. About three years later he entered on private practice in Vancouver, B. C., and with the exception of an interval with the British Columbia General Contract Company, continued in private practice until 1909, when he entered the service of the Department of Public Works of Canada, being appointed superintendent of dredging for British Columbia. In December 1912 Mr. Bayfield was made chief engineer in charge of all estimating and designing of the Vancouver Machinery Depot Company, where he remained until 1913, when he was again called upon by the Dominion Government to design a self-propelling hydraulic dredge. In 1914 he returned to private practice at Vancouver, B. C., engaging principally in consulting work in connection with dredging and marine matters, but was called in 1915 to the Department of Railways and Canals of Canada to take the position of mechanical engineer in charge of all mechanical and marine work at Port Nelson, Manitoba. Late in the same year Mr. Bayfield became chief engineer with Norton, Griffiths & Co., Ltd., St. John, N. B., in connection with the harbor-improvement contract. In 1916 he was called on by the British Ministry of Munitions of War to take charge of the Enfield rifle production at the Winchester Repeating Arms Company, New Haven, Conn., where he remained until the summer of 1917, when he was appointed engineer in charge of the Ogden Point assembly plant of the Imperial Munitions Board, Victoria, B. C. He held this position at the time of his death, February 12, 1918.

Mr. Bayfield was a member of the Institution of Mechanical Engineers (Great Britain) and an associate member of the Canadian Society of Civil Engineers. He became a member of our Society in 1913.

ROBERT ELLSWORTH JACKSON

Robert E. Jackson was born in Matteawan, N. Y., on August 24, 1888. He was educated in the public schools of Garfield, N. J.

He served his apprenticeship with the Dutchess Tool Works, Fishkill Landing, N. Y., and there learned the machinist's trade. The year of 1910 he spent with the Coldwell Wilcox Company, Newburgh, N. Y., as machinist. He then worked in the same capacity for about six months with the Fiat Automobile Company, Poughkeepsie, N. Y. Upon leaving this company he became associated with P. H. Gill & Sons, Brooklyn, N. Y., as machinist. In April 1911 he entered the employ of the Edison Laboratory, West Orange, N. J., as foreman of the machine department. He was later made superintendent and held this position at the time of his death.

Mr. Jackson became a junior member of the Society in 1917. He died at West Orange, N. J., on April 5, 1918.

ERNEST AINSWORTH MOORE

Ernest A. Moore was born in Victoria, Australia, on October 11, 1879. He was educated in Melbourne, Australia, and later received special instruction in work of a mechanical nature from tutors.

While in Australia he was employed by Knox, Schlapp & Co., who represented the Allis-Chalmers Company, in the capacity of private secretary to Mr. William Knox. In 1904 Mr. Moore decided to come to the United States and in August of that year became draftsman with the Filer & Stowell Co., Milwaukee. Two years later he became connected with the Allis-Chalmers Company, working first in the gas-engine department, and later as assistant engineer. In 1908 he became chief engineer of the Bates Machine Company, Joliet, Ill., having full charge of all technical and later all commercial engineering work; he designed, built and supervised a great amount of special machinery and while with this company obtained his experience in work of a consulting and legal technical nature.

Mr. Moore left the Bates Machine Company in 1913 to take the position of resident manager in Chicago for the A. M. Byers Company, Pittsburgh, manufacturers of wrought-iron pipe. About May 1914 he left Chicago for Detroit, planning to develop there a new business for the production of a new machine making paper containers. This machine was first designed by him in 1911 and was gradually perfected, until in 1914 the Moore Container Company was organized in Detroit with Mr. Moore as president. Plans were practically completed for the manufacture of the machine when his health failed and he was forced to give up his work completely and leave for the West in an effort to regain his strength. He died very suddenly in Phoenix, Ariz., on February 15, 1918.

Mr. Moore became a member of the Society in 1913.

WILLIAM PRESCOTT SARGENT

William P. Sargent was born in Stoneham, Mass., on September 9, 1878, and received his early education in the public schools of that city.

He was first employed in 1896 by Prentice Brothers, Worcester, Mass., manufacturers of machine tools, where he had charge of the stock room. His spare time he devoted to learning machine operation and machine fitting. His next position was with the Draper Machine Tool Company as draftsman. For a short while thereafter he was connected with the Lodge & Shipley Machine Tool Company, Cincinnati, as a designer of special machinery. In 1903 he was made special engineer for the Niles Tool Works, Hamilton, Ohio, where his work dealt with chemical and metallurgical research problems. He returned to the Pratt & Whitney Co. as assistant construction engineer in the design of the machine shop, foundry and power plant which were being erected. He was next made engineer in direct charge of the design and construction of the machine and forge shop of the Niles Tool Works. About 1907 Mr. Sargent became associated with the Barber-Colman Company, Rockford, Ill., as engineer to design and develop automatic textile machinery. From 1909 to 1915 he was engaged in the design and development of automatic machinery for handling periodicals, papers and paste, and in the design and construction for the Bureau of Chemistry of several graphic machines for recording impacts and stresses. He was associated also with the Curtis Publishing Company, Philadelphia, where he was interested in the reduction of labor costs in the mechanical processes involved in the publication of 5,000,000 magazine copies a month. During the years of 1915 and 1916 Mr. Sargent devoted his time to coördinating the facilities of more than twelve small shops whose production singly of gages, tools and ordnance parts would not have been appreciable. Recently Mr. Sargent was engaged in the construction of gages and interested in other work for the Frankford Arsenal.

Mr. Sargent became a member of the Society in 1909. He died on April 10, 1918.

WILLIAM WARREN SMITH

William W. Smith was born in Toronto, Canada, on September 9, 1876. He was educated in the public schools of Michigan and in Michigan Agricultural College, taking the mechanical-engineering course. Later he attended Purdue University, where he took special work in mechanics.

He obtained his shop experience with the Welded Steel Barrel Company, Detroit, Mich., where for about a year and a half he was draftsman and inspector. He spent two years with the American Car and Foundry Company, Detroit and St. Louis, as draftsman, estimator and finally as chief draftsman. His next position was with the Standard Steel Car Company, Pittsburgh, as assistant construction engineer, where he remained for about a year, leaving to become assistant manager with the Mexican Car and Foundry Company, Mexico City. He remained in Mexico, transferring his business connections to the National Iron and Steel Works as superintendent and mechanical engineer in charge of design for miscellaneous machine and structural-steel work. About 1916 Mr. Smith became associated with Dodwell & Co., New York, as foreign representative with Behn Brothers, San Juan, Porto Rico. In February of this year he joined the sales force of the Allis-Chalmers Manufacturing Company, expecting later to be transferred to sales work in South America, with which country he was especially familiar.

Mr. Smith became a member of the Society in 1909. He died in Milwaukee, Wis., on April 1, 1918.

ROLL OF HONOR

ALEXANDER, LUDWELL B., First Lieutenant, Aero Section, Signal Officers' Reserve Corps, School of Military Aeronautics, Massachusetts Institute of Technology.

ANTOSCH, WALTER, Ensign, United States Naval Auxiliary Reserve.

BALLOU, J. LADD, Sergeant, Co. C, 342d Inf., Camp Grant, Ill.

BARKER, EARNEST S., First Lieutenant, Headquarters Co., 48th Infantry, Camp Stuart, Newport News, Va.

BARRON, ALEXANDER F., Private, Co. F, 305th Engineers, Camp Lee, Va.

BARRY, JOHN L., JR., Ensign, Engineering, U. S. Naval Auxiliary Reserve.

BECHTEL, JOHN A., Captain, Co. F, 108th Supply Train, 33d Division, U. S. Expeditionary Forces, France.

BOYER, GEORGE H., First Lieutenant, Ordnance Training Camp, Camp Hancock, Augusta, Ga.

BRIGGS, LESTER G., U. S. Navy Aviation.

BUCK, J. E., Ensign, U. S. Naval Reserve Force.

CARPENTER, F. S., First Lieutenant, Signal Corps, U. S. Army.

CLARKE, LEON L., Captain, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

DAYTON, BIRGE S., Private, Co. C, 6th Regiment, U. S. Engineers, American Expeditionary Forces, France.

DICKSON, CHARLES H., First Lieutenant, Ordnance Officers' Reserve Corps.

DOUGLAS, MORRIS D., First Lieutenant, Ordnance Officers' Reserve Corps, Inspection Division, Ordnance Dept.

EKSTRAND, CHARLES E., Lieutenant (Junior Grade), U. S. Naval Reserve Force.

GIANELLONI, VIVIAN J., Lieutenant, Coast Artillery Reserve Corps, Co. B, 53d, A. T. C. A. C., Oakland, Cal.

GOLDSMITH, CLARENCE, Major, Construction Division, Quartermaster's Corps, U. S. Army.

HAMILTON, W. B., Captain, Ordnance Officers' Reserve Corps, Division of American Ordnance Base Depot in France.

HOSMER, FRED E., Lieutenant, Assistant Engineer Officer, Headquarters Staff, Aviation Section, Ebberts Field, Lonoke, Ark.

JACKSON, DUGALD C., Major, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

JACKSON, E. R., First Lieutenant, Ordnance Officers' Reserve Corps, Inspection Division, Ordnance Dept., U. S. A.

JACKSON, WILLIAM B., Major, Quartermaster's Corps, U. S. A., Officer in Charge of Utilities, Camp Merritt, N. J.

LYNE, L. F., First Lieutenant, Ordnance Officers' Reserve Corps, Inspection Division, Ordnance Department, U. S. Army.

McKAIG, W. W., Ensign, Bureau of Construction and Repair (Aviation), Navy Dept.

McNALLY, EDWIN M., Ensign, U. S. Naval Reserve Force, Bureau of Steam Engineering, Navy Department.

MARROW, GEORGE P., Major, United States Army.

MERRILL, S. CLIFFORD, Second Lieutenant, Ordnance Officers' Reserve Corps, Inspection Division, Ordnance Department, U. S. Army.

MORSE, WALTER R., Captain, N. A., 301st Engineers, Camp Devens, Mass.

MUNYAN, EARL A., Lieutenant (Junior Grade), U. S. Naval Reserve Force, Navy Department, Bureau of Ordnance.

NORTHCROFT, JAMES F. S., Officers' Training Camp, British Army, England.

PLANK, WILLIAM J., Cadet, Aviation Section, Signal Enlisted Reserve Corps, School of Military Aeronautics, Austin, Tex.

ROBECHEK, B., 21st Co., Coast Artillery Corps, Ft. Preble, Me.

ROBERTS, CHAPIN, Ensign, U. S. Naval Reserve Force, U. S. S. *Hawk*.

ROSE, DAVID, Private, Co. C, Second Provisional Ordnance Bureau, American Expeditionary Forces, France.

SAWYER, WILFRED D., Private, Camp Funston, Tex.

SCHALLER, ALWIN L., Captain, Ordnance Department, N. A., Aberdeen Proving Ground, Md.

SEATON, EDWARD W., Private, Ordnance Corps, Detachment A, Gunpowder Reservation, Barracks 2, Edgewood, Md.

SEWARD, HERBERT L., Lieutenant (Senior Grade), U. S. Naval Reserve Force, Navy Steam Engineering School, N. Y.

SMOCK, HAROLD E., U. S. Naval Reserve Force, stationed at Dayton, Ohio.

SMITH, FURMAN, JR., Lieutenant, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

TAYLOR, PAUL H., First Lieutenant, Ordnance Officers' Reserve Corps, 26th Division, Ordnance Mobile Repair Shops, American Expeditionary Forces, France.

TAYLOR, STEVENSON, Lieutenant-Colonel, U. S. Naval Reserve Force.

THURSTON, EDWARD D., JR., Lieutenant (Junior Grade), U. S. Naval Reserve Force, U. S. Navy Gas-Engine School, Columbia University, N. Y.

WALSH, EDWARD T., Major, Ordnance Officers' Reserve Corps, Inspection Division, Ordnance Department.

WELLING, LINDSAY H., Sergeant, 117 Mobile Ordnance Repair Shop, American Expeditionary Forces, France.

WETHERILL, WILLIAM C., Ensign, U. S. Naval Reserve Force.

WOODWORTH, C. B., Captain, 49th Engineers, Fort Meyer, Va.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JULY 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 79.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by July 10, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about July 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Connecticut

BALDWIN, CHARLES A., Assistant General Sales Manager, Bridgeport Brass Co., Bridgeport

LUDEMAN, OSCAR H., Engineer and Salesman, The Spencer Tubine Cleaner Co., Hartford

SHAW, STILLMAN, Mechanical Engineering—Lorenz & Lorenz, Hartford

Delaware

CRAIG, WILLIAM D., Engineer, Atlas Powder Co., Wilmington

District of Columbia

DOYLE, EDMUND A., 1st Lieutenant, Engr. R. C., U. S. Army, Washington

FISCHER, LOUIS A., Major, Ordnance Reserve Corps, Bureau of Standards, Washington

Georgia

PERRY, HIRAM W., General Superintendent, Yaryan Rosin & Turpentine Co., Brunswick

Illinois

McWETHY, FRANK H., Secretary, Stephens-Adamson Mfg. Co., Aurora

OLSON, CARL G., Chief Engineer, Illinois Tool Works, Chicago

Maryland

SYMINGTON, THOMAS H., President of the several Symington Companies, Baltimore

Massachusetts

GRADE, OSCAR W., Mechanical Engineer, Worthington Pump & Machy. Corp., Blake & Knowles Works, Cambridge

HARVEY, John C., with C. M. Allen, Engineer, also owner and manager Haynes automobile business, Worcester
INGRAM, Edward H., Mechanical Engineer, Greenfield Tap & Die Corp., Greenfield
JONES, Evan F., Treasurer and General Manager, Morgan Spring Company, Worcester
LINCOLN, Frank S., Machine Purchase & Tool Designer, Construction Department, Watertown Arsenal, Watertown
REID, Alexander, Manager of Water Wheel Dept., Holyoke Machine Companies, Worcester

New Jersey
FRENCH, Charles M., 1st Lieutenant Engineers R. C., 34th Engineers, Camp Dix
GIBBONS, Archer, Manager of General Office Service Departments of Thomas A. Edison, Inc., Orange
PARRISH, Samuel M., Power Supervisor, The Celluloid Co., Newark

New York
LATTER, Edward D., Industrial Engineer, with Federal Accounting Corp., New York
MOREAU, L., Engineer, with M. M. Schneider & Co., New York
POLLARD, Wright, Supervisor, Remington Arms & U. M. C. Co., Inc., Ilion
POTTER, Joseph S., General Superintendent, Gas Engine & Powder Co., & Charles L. Seabury & Co., Consol., Morris Heights
VAN BOMEL, Leroy A., President, Sheffield Condensed Milk Co., Inc., Asst. General Manager, Sheffield Farms Co., Inc., President, High Bridge Garage, Inc., New York
WILDER, Robert H., General Inspector, American Metal Products Corp., New York
WAINRIGHT, Walter S., Engineer, Walter Kidde & Company, Inc., New York

North Carolina
MACEWAN, Thomas A., Mechanical Construction Engineer in Private Practice, Greensboro

Ohio
LEAHY, Francis W., Inspector of Machinery, U.S.S.B. Emergency Fleet Corp., care of Hooven, Owens, Rentschler Co., Hamilton
McCONKEY, Walter N., Shop Engineer, Lima Locomotive Works, Inc., Lima
RUCK, Edward H., Chief Engineer, The Cleveland Tractor Co., Cleveland

Pennsylvania
BUCK, Charles A., Vice President, Bethlehem Steel Co., Bethlehem
ENZIAN, Charles, Mining Engineer, Philadelphia and Reading Coal and Iron Co., Pottsville
GUTHRIE, Bayard, Superintendent of Crucible Works, Crucible Steel Co. of America, Pittsburgh
HOFAMMANN, Karl E., Assistant Foreman, Pennsylvania Railroad Company, Altoona
SCHLATTER, Louis H., Assistant Foreman, Pennsylvania R. R. Co., Test Dept., Altoona

Tennessee
SEWELL, Charles B., Saw Mill Designer and Builder, Newport

Virginia
VANDEGRIFT, Wayne A., Supt. of Const., J. W. Danforth Co., Naval Base Station, Norfolk

Wisconsin
ERBACH, William L., Vice-President & Manager, Riethrock Land & Lumber Co., Athens

Canada
COSLER, Arthur S., Adviser on Pulp-Mill Construction, Fraser Companies, Ltd., Edmundston, N. B.
FRASER, Duncan W., General Manager, Montreal Locomotive Works, Ltd., Montreal

Canal Zone
HEDGES, Selby E., Plant Draftsman, Mechanical Division, Panama Canal.

South America
BARKER, Edgar E., Superintendent of Mines, Cerro de Pasco Copper Corp., Cerro de Pasco, Peru

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Alabama
DREXELIUS, George W., Local Manager, The Fairbanks, Birmingham

Illinois
REDFIELD, Edmund R., Mechanical Engineer, Russell, Burdsall & Ward, Bolt & Nut Co., Rock Falls

Iowa
NICHOLSON, James M., Fuel Supervisor, care of A. T. & S. F. Ry. Co., Fort Madison

Michigan
LANGILL, Ross E., Chief Engineer, Sawmill Dept., The Prescott Co., Menominee

Missouri
HILL, William S., Superintendent, Light & Power Dept., Springfield Gas & Electric Co., Springfield

New Jersey
PONSEN, Lyas, Power-plant Engineer, Babcock & Wilcox Co., Bayonne

New York
GRAHAM, Warren W., Mechanical Engineer, Ford, Bacon & Davis, New York

Pennsylvania
BENNETT, Leland W., Instructor, Dept. Mechanical Engineering, University of Pennsylvania, Philadelphia

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

District of Columbia
COLLINS, Lester W., Investigator in Marketing Fruits and Vegetables, Bureau of Markets, Washington

Massachusetts
STRUCK, Henry W., Mechanical Designer, Stone & Webster, Boston
TUCKER, Harold B., Asst. Supt. Const., Merrimac Chemical Co., No. Woburn

Minnesota
KOPPER, Edward, Jr., Chief Engineer, Minnesota Manufacturers' Assn., North St. Paul

Nebraska
BIRD, Frank S., Superintendent of Construction, Phoenix Construction Co., Omaha

New Jersey
BELDING, Lewis A., Assistant Professor of Mechanical Engineering, Stevens Institute of Technology, Hoboken.
RILEY, Arthur B., Sergeant, 1st Class, in charge of road construction, Utilities Dept., Quartermaster Corps., U. S. Army, Camp Merritt
SCOTT, Walter C., Manager and member of firm—Walter Scott & Co., Plainfield

New York
ANDRESEN, John H., Jr., Mechanical Superintendent, New York American Journal, New York
BROOKS, John, Assistant to General Manager, Russell Motor Car Co., Inc., Buffalo
SANBORN, Arthur P., Engineering Ensign, U.S.N.R.F., Section Base, No. 8, Tompkinsville, Staten Island

Ohio
BOHANNON, George L., Chief Engineer, The Youngstown Steel Car Co., Youngstown
DRUMMOND, John H., President, The Drummond-Miller Co., Cleveland

Pennsylvania
BAGLEY, Glen D., Engineer for Mellon Institute of Industrial Research, Pittsburgh
PRUDDEN, Theodore M., 1st Lieutenant, Ordnance Dept., R. C., Frankford Arsenal, Philadelphia
SMITH, Victor J., 1st Lieutenant, Ordnance R. C., U.S.A., Frankford Arsenal, Philadelphia

Virginia
McCLAVE, Bernard D., Captain, Sanitary Corps, N.A., Assigned to A. S., S. C., Hampton

West Virginia
KAUFMAN, Morris L., Engineer in Cotton Purification Dept., Staff of Lt. Col. Arthur Wass, Nitro

FOR CONSIDERATION AS JUNIORS

California
BEATTIE, Joseph A., Assistant Engineer, Board of Public Utilities, Los Angeles

Connecticut
STURTEVANT, Henry S., Mechanical Engineer, S.K.F. Ball Bearing Co., Hartford

Indiana
DAVIDSON, John L., Chief Inspector for the Ordnance Department, U. S. Army, care of The Illinois Steel Co., Gary

Maryland
BELL, Walter M., Engineer, U. S. Filling Plant, Co. B., Gunpowder Reservation, Edgewood

Michigan
MEHARD, Hugh R., Time Study Chief and Efficiency Engineer, The Aluminum Castings Co., Detroit

New Jersey
GOTTLIEB, Solomon, Departmental Manager, American Lead Pencil Co., Hoboken

New York
LEGGE, Elmer E., Mechanical Engineer and Metallographist, Watervliet Arsenal, Watervliet
WATKINS, Roy A., Ensign, Instructor, Columbia University, New York

Pennsylvania
MARQUARDT, William C., Asst. Superintendent, Nelson Valve Co., Philadelphia
McCABE, P. Charles, Heating Engineer, The Austin Company, Philadelphia

Canada
GUSTAFSON, Alfred O., Checker, Engineering Dept., Willys-Overland, Ltd., West Toronto

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE-MEMBER

Connecticut

PIGOTT, REGINALD J. S., Superintendent, Raw Material Depts., Bridgeport Brass Co., Bridgeport

New York

HATCH, EDWIN G., Consulting Engineer and Manufacturer, New York

Pennsylvania

BRYANS, HENRY B., Engineer, Counties Gas & Electric Co., Norristown

PROMOTION FROM JUNIOR

District of Columbia

HALSEY, WILLIAM D., Asst. Professor, Mechanical Eng., Geo. Washington University, and Mechanical Engineer with National Advisory Committee for Aeronautics, Washington

Massachusetts

HAYES, J. HOWARD, Member of firm, E. H. Hayes Machinery Co., Boston

New Jersey

ABRAMS, FRANK W., Asst. Superintendent, Standard Oil Company, Jersey City

SMITH, WILLIAM E., Traveling Engineer, Babcock & Wilcox Co., Bayonne

STROUSE, SIDNEY B., General Engineering Practice and District Manager for Warren Webster & Co., Atlantic City

New York

GATES, JOHN G., Production Superintendent, Sperry Gyroscope Company, Manhattan Bridge Plaza (Reinstatement), Brooklyn

Ohio

RENTSCHLER, GORDAN S., Vice-President and Works Manager, The Hamilton Foundry & Machine Co., Hamilton

Pennsylvania

BICKLEY, JOHN H., Designing Hydraulic Engineer, W. H. Wood, Media

LEWIS, GEORGE C., Chief Engineer, Hersh & Brother, Allentown

MANN, HARVEY B., Department Manager and Director, Dravo-Doyle Company, Pittsburgh

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

Members applying in person for Government positions at such places as Navy Yards should invariably make appointments beforehand by letter, telephone or telegraph, and arrange to have passes or the equivalents so that they can gain entrance. In this way they will avoid disappointment.

TECHNICALLY TRAINED MEN AS INSTRUCTORS in Government schools for automobile mechanics and military aeronautics. Men within the draft age can be used for this work, provided they have not already been called by their Local Draft Board. 2611.

ASSISTANT RESIDENT INSPECTORS. Several recent graduates of technical schools to supervise the construction work on hulls and installation of the machinery. Salaries from $1200 to $1500. Location, New York. 2612-A

SEVERAL ENGINEERS of mature experience and with some acquaintance with the principal parts of steamships to be in office to help in directing work. Salaries range from $1500 to $3000. Location, New York. 2612-B.

DIESEL ENGINEER. Technical department of Emergency Fleet Corporation requires the service of experienced Diesel engineer who should also have knowledge of shop practice. 2613.

NUMBER OF HIGH-GRADE TECHNICAL MEN wanted for positions in industrial establishments by the United States Army Ordnance through the Civil Service, as follows:

SUPERINTENDENTS for plants engaged in chemical manufacturing processes; salaries range from $2400 to $6000. Assistant superintendents of nitrate and chemical plants, $1600 to $2400.

CHEMICAL ENGINEERS to have complete supervision over one or more chemical manufacturing processes incidental to the war. Salaries from $2400 to $6000. Some with less experience as chemical engineers to receive from $1600 to $2400.

GAS-MANUFACTURING EXPERT to receive $1600 to $2400 a year.

MECHANICAL ENGINEERS experienced in operation and control of high-pressure hydraulic and gas machinery. Salaries for junior mechanical engineers from $1600 to $2400.

POWER-HOUSE ENGINEERS for supervision of operation. Salaries from $1800 to $2400.

MACHINE SHOP FOREMEN. Salaries $1,800 to $2400 a year.

Education and experience of men will qualify them without necessity of Civil Service Examinations.

Persons of military age accepting appointment will not avoid the obligations of the Selective Service Law. No application will be accepted from employees of firms or corporations engaged in contracts for the Government or its Allies unless written assent to such application is given by the head of the establishment that might be seriously handicapped in its war work by the loss of the man.

Many positions are open. The needs of the service, the Ordnance Department announces, are so imperative that applications will be received indefinitely. Further information regarding the Army Ordnance positions that must be filled is obtainable from the Civilian Personnel Section, United States Army Ordnance, 1330 F Street, Washington, D. C.

CIVILIAN POSITIONS

EXPERIENCED COPY WRITER to handle building construction and equipment accounts; exceptional opportunity with New England agency for man who knows the contracting field and can show satisfactory evidence of ability through copy and catalogue matter already written. 0267-F.

MECHANICAL DRAFTSMAN, preferably draft-exempt, for machinery and building layouts, mill specifications, design of experimental and new machinery. Permanent position. Attractive surroundings. Location, New Hampshire. 0268-F.

YOUNG MEN for sales, productive and experimental engineering work in large electrical manufacturing firm in Middle West. Applicants must have complete high-school training and the equivalent of at least two years' technical training; preferably be technical graduates from a university of good standing. In reply state training and experience in detail, salary desired, draft classification and references. 0269-F.

POWER SUPERINTENDENT to take charge of a large power plant near New York City. In reply state nationality, age, education, experience in full, and salary expected. Location, New Jersey. 0275-F.

SUPERINTENDENT of textile machine-shop, employing 50 men; preferably a graduate of Mass. Inst. Technology. Location, New Jersey. 0276-F.

COST CLERK AND ACCOUNTANT for concern manufacturing structural steel materials and hardware specialties; familiar with modern methods of accounting, statistical work and cost keeping. Familiarity with stenography of advantage. Location, New York City. 0277-F.

DRAFTSMAN experienced in machinery, pipe layouts, etc. Salary, $40. Headquarters, New York. 0278-F.

MECHANICAL ENGINEER to increase production and development of goods. Location, Middle West. 0279-F.

ASSISTANT TO HEAD OF BALLOON DEPARTMENT. Must speak French. Competent to develop production and improvements in design. Location, Middle West. 0280-F.

EXECUTIVE, of college professor type, with personality to meet and gain confidence of customers and direct the activities of a large physical laboratory. Location, Middle West. 0281-F.

DIRECTOR OF WELFARE WORK and general plant cooperation with heads of departments and employees. Location, Middle West. 0282-F.

ASSISTANT SUPERINTENDENT in large paper-box manufacturing plant. Man with technical education preferred. Experience in manufacturing desirable. Position requires man with tact and ability to handle large amount of detail. Location, Indiana. 0284-F.

MECHANICAL ENGINEER to oversee the testing of fabrics, glue, dope, varnish, structural tests, sand-load panels, etc. Location, Buffalo. 0285-F.

MASTER MECHANIC to take entire charge of maintenance work, including machinist, millwright, carpenter, electrical and pipe-fitting work. Salary about $150 per month to start; good chance for advancement. Locality, Brooklyn. 0286-F.

STATISTICIAN to compile engineering data. Recent college graduate preferred. Salary, $25 per week. Locality, New Jersey. 0287-F.

ASSISTANT EMPLOYMENT MANAGER. Man of some mechanical training wanted. Location, Connecticut. 0288-F.

DRAFTSMEN for Connecticut plant. Men of recognized ability desired. 0289-F.

TIME-STUDY WORK for men of ability. Location, Connecticut. 0290-F.

DRAFTSMAN, designer of hoisting engines and hoisting machinery generally. American citizen. Salary $150 to $200 a month. Must be experienced and capable designer. 0291-F.

DRAFTSMAN, of good education; experienced in steam-piping work, ventilating, etc. Salary $100. 0292-F.

ASSISTANT TO GENERAL SUPERINTENDENT of Canadian plant. Chemical graduate. Previous experience in the manufacture of smokeless powder very much desired, though not absolutely necessary, or previous experience in the manufacture of powder for high explosives. Salary, $3000 to $3500. 0293-F.

MECHANICAL DRAFTSMAN of not less than two years' experience to work in engineering department of well-established and growing business, doing light structural and mechanical work. State age, nationality, education and experience, also references, accompanying reply with sample of lettering. Location, New York City. 0294-F.

DRAFTSMEN for plant layouts of machinery and equipment. Location, New York. 0296-F.

ASSISTANT ENGINEER, graduate of ability and initiative. Experience in structural steel work and supervision of construction desirable. Location, Illinois. 0295-F.

CHIEF ENGINEER for cement corporation plant aggregating 3000 hp., and comprising Corliss engines, a. c. generators, motors, etc.; plant in excellent condition. 0297-F.

FACTORY SUPERINTENDENT, 31 years of age or over, to take charge of works for factory employing about 200 men. One who has had an all-round experience and capable of handling employees. Salary at start, between $4000 and $5000. Location, New York. 0298-F.

MACHINE DESIGNER with some experience in electrical apparatus, and familiar with automatic-machine design and electrical appliances. Salary from $1800 to $2400. Location, New York State. 0299-F.

DESIGNING DRAFTSMEN, with some experience on printing-press work and shop experience. 0300-F.

DRAFTSMEN, experienced in boiler and power-plant equipment, able to check drawings. Salary depends on man. Location, New York City. 0303-F.

YOUNG TECHNICAL GRADUATE to develop as superintendent. Must be draft-exempt or above draft age and have personality to handle men. Salary $2000 to $2600. Location, New Jersey. 0304-F.

MAINTENANCE MECHANICAL ENGINEER, for plant employing 5000 men. Experience in belt transmission, electric, steam, air and gas service, plumbing, etc., and as millwright, tinsmith, electrician, etc. Salary depends on man. Location, New Jersey. 0305-F.

MECHANICAL DRAFTSMEN, conveying machinery. Young technical graduates preferred. Salary, $125. Location, New York. 0306-F.

ENGINEERS and ASSISTANT ENGINEERS in forest products. Work embraces principally investigations of mechanical and physical properties of wood in airplane construction, methods of artificial drying, etc. Salaries range from $1800 to $2400 for engineers, and from $1200 to $1500 for assistant engineers. Location, Wisconsin. 0307-F.

ASSISTANT, to take charge of design and construction of motors, etc., in shop. Personality essential factor. Technical graduate preferred. Salary, $2500. Location, New York. 0308-F.

OPERATING ENGINEER, high-grade man for light, heat and power. Location, New Jersey. Salary depends upon man. 0311-F.

SALES ENGINEER for large corporation; experience in sale of semi-Diesel fuel-oil engines. Only high-class salesman with successful record considered. 0313-F.

DRAFTSMEN, mechanical, electrical, structural, reinforced concrete. Location, Pennsylvania. 0314-F.

OFFICE ENGINEER to take charge of complete design of blast furnaces, steel plants, power plants, etc. Location, Ohio. 0315-F.

YOUNG ENGINEER, over draft age, single, to go to head office in Chile, S. A., of company operating several plants in nitrate district; should have some experience in industrial cost analysis and efficiency work, in addition to general engineering experience. Salary, $3000 a year to start. 0316-F.

PLANT ENGINEERS or HIGH-GRADE DRAFTSMEN for plant engineering work. Location, New Jersey. 0317-F.

ASSISTANT EMPLOYMENT SUPERVISOR to secure men for Government work. Salary depends on man. Must be American citizen. Location, Brooklyn. 0318-F.

ENGINEERS to travel throughout the country and get in touch with employers and

with men not engaged in war work, and to secure competent men for concerns doing Government work. Location, New York. 0319-F.

PRODUCTION ENGINEER, man with good executive ability. Location, Michigan. 0320-F.

MAN WITH MECHANICAL AND BUSINESS ABILITY, who understands sheet-iron work, capable of taking charge of a small plant. Permanent position. Location, New York. 0321-F.

DRAFTSMAN wanted for mechanical department of smelter plant producing spelter and sulphuric acid. Locality, Pennsylvania. 0323-F.

HIGH-GRADE SHOP EXECUTIVES FOR IMPORTANT WAR WORK, shop superintendents, shop foremen, master mechanic, construction engineer. 0326-F.

SALES MANAGER to organize sales force for concern manufacturing metal-sawing products. Salary, $5000. 0327-F.

EXECUTIVE FOR ENGINEERING DEPARTMENT to take charge of technical end of steam and power-pump line. Locality, Kentucky. 0328-F.

MECHANICAL DRAFTSMEN with technical education, experienced in vacuum-heating systems and high-pressure steam-piping. Location, New York City. 0329-F.

ORGANIZATION MAN to handle placing of orders and correspondence relative thereto for forgings. Position would be one of considerable importance and would require accuracy, a good knowledge of correspondence, planning, scheduling, etc. Salary, $3000. Location, Washington, D. C. 0330-F.

DRAFTSMEN in architectural lines for work on factory buildings. Location, New York. 0334-F.

YOUNG MAN, DRAFT EXEMPT, for sales department at general office of large corporation. With mechanical education, sales-department experience, preferably familiar with semi-Diesel fuel-oil engines. State education, age, experience, etc. Applications strictly confidential. Location, Michigan. 0335-F.

DRAFTSMEN with experience in conveying machinery and general engineering. Salary, $175 to $200. Location, New Jersey. 0336-F.

YOUNG ENGINEER with executive ability, and some experience, to serve as master mechanic in charge steam and electric plants and kilns, and general maintenance. Location, Michigan. 0337-F.

ENGINEERS, DESIGNERS and DRAFTSMEN wanted for work of research, development, and design related to problems of telephonic, telegraphic and radio communication which are matters of public importandce. Both temporary and permanent positions are open. Location, New York. 0338-F.

YOUNG ENGINEER to start with growing concern in drafting and miscellaneous work, estimating, superintending construction work, etc. Salary not over $1200 to start. Headquarters, New York. 0339-F.

PRODUCTION MANAGER with estimating experience in machine shop and on machine tools. Men of 30 to 40 years of age preferred. Salary, $2500 to $3000. Location, New York City. 0340-F.

TOOL MAKERS, DESIGNERS or MACHINISTS for manufacture of dies, gages, jigs and fixtures. Location, New Jersey. 0341-F.

DRAFTSMAN, on vertical triple-expansion marine engines for shop in western New York. Permanent position and excellent opportunity for the right man. 0342-F.

ENGINEER to head section interested in fuel problems connected with Government power plants, also carrying on laboratory investigations of boiler-room instruments, devices and house-heating apparatus. Man is needed to head section who has leaning toward investigation work rather than the commercial phase of engineering. Salary, $2500. 0343-F.

INVESTIGATOR in powdered-fuel work, for Government laboratories, one not interested in any commercial organization of powdered fuel industry; must be well posted and able to follow the needs of this field by laboratory investigations. Salary, $2500. 0344-F.

ENGINEERING CHEMIST, specially proficient in tests of city gas plants and the production of retort coke. Salary, $2500. Location, Illinois. 0345-F.

DRAFTSMEN. Some experience in chemical plants. Location, New York. 0346-F.

MECHANICAL DRAFTSMEN, experienced in power-transmission and machinery layouts. Work in question will probably be over two months' duration and good salaries will be paid competent men with traveling expenses from New York to West Virginia and return, and living quarters. 0347-F.

FACTORY SUPERINTENDENT. Prominent corporation, manufacturing light product of large variety, part stock, part special to order, requires aggressive, energetic factory superintendent, thoroughly experienced in machine-shop practice and modern centralized planning control methods, capable of securing large production efficiently and economically. To be considered, replies must fully state experience and qualifications. 0348-F.

MAINTENANCE ENGINEER for machine shops and foundry of growing plant in Providence. Technical graduate preferred. 0349-F.

YOUNG CONSULTING ENGINEER, to act as personal understudy to consulting engineer. Man who has mechanical-engineering ability combined with all the knowledge of economics and statistics possible. Prefer men three years out of college, exempt from draft. Unusual opportunity through the educational features of the work. 0351-F.

MECHANICAL DRAFTSMEN. Men familiar with large power-station work. Immediate work in hand is the installation of a 20 000 kw. turbo-generator with the necessary condensing apparatus, boilers, stokers, coal and ash-handling apparatus, etc. Salary $150 per month. 0352-F.

MACHINE DESIGNERS on fixtures, jigs, etc. Flat salary of $35 and opportunities at high rates by the hour. Location, Connecticut. 0363-F.

LABORATORY INSTRUCTOR for large New York City University, one capable of taking charge. Work covers the entire range, with the exception of materials testing, and includes hydraulics. 0354-F.

SALES ENGINEER, one energetic and willing to work. Must be a thinker. Engineering college degree with some experience in shop work and machine design, or a high-school education with two or three years' shop work and machine design. Must be between 25 and 32 and draft exempt, or in class 4. Salary, $1500 to $1800. Location, New Jersey as headquarters. 0355-F.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL AND EFFICIENCY ENGINEER, Member, age 37, married; 16 years' wide experience in mechanical and electrical engineering, seven years of which was as directing engineer with large professional efficiency engineering company. Reason for changing is that present position does not permit of future advancement. Desires position of executive nature with progressive concern where ability will be recognized and responsibilities increased proportionally. Only permanent connection will be considered. F-146

GENERAL MANAGER of light and power company, for past seven years in responsible position in steam-driven electric and ice-making plant, desires similar position with company having larger field. American born, 39 years of age; high-class reference; well versed in plant upkeep and operation. F-147.

MECHANICAL-ELECTRICAL ENGINEER, technical graduate 1904, now employed as mechanical engineer and superintendent of two modern turbine steam plants and gas plant, desires to make connection with progressive public utiity or industrial plant where ability, integrity, and reliability will be appreciated. Experienced in handling men, in design, construction and maintenance of high and low-voltage stations, steam plants, piping, machinery, buildings and various kinds of steam and electrical equipments. Unusual business and technical training. Speaks French fluently. Best references. Location preferred, Eastern States. Salary, $3000 per year. F-148.

MECHANICAL ENGINEER, M. E. graduate, age 32, not in draft, married; eight years' experience in design and manufacture of automobiles, motor trucks, spark plugs, production tools, small punch and die work, inspection gages, and a large variety of small and medium sized special and semi-automatic machinery. Two years in executive position. Thorough and systematic. General knowledge of accounting principles and efficiency work. Salary secondary to opportunities and surroundings. At present employed. F-149.

SALES ENGINEER, electrical-mechanical, technically trained, age 35; speaks Spanish and Portuguese fluently, and has good knowledge of Italian and French. At present employed, but desires to change to larger possibilities. F-150.

GENERAL SUPERINTENDENT, mechanically and technically trained, thoroughly conversant with modern methods of produc-

[illegible] company [illegible] Has [illegible] of typewriter, adding [illegible] speedometer [illegible] installation [illegible] control of large scale pro[illegible] Salary, $5000. F-151.

METALLURGICAL ENGINEER. Junior member and technical graduate, age 27, single, draft-exempt, desires position as assistant executive in production or control work. Has had broad experience covering foundry, machine shop, cost, drafting, efficiency and construction work. Has specialized in metallography, electrometallurgy and pyrometry. Salary will depend on future possibilities. F-152.

GENERAL SUPERINTENDENT OR SUPERINTENDENT. Associate-member, diplomatic and forceful executive, accustomed to supervising from one hundred to one thousand employees. Fifteen years' general mechanical experience. F-153.

MECHANICAL ENGINEER, age 35, technical graduate with thirteen years' experience in the design and manufacture of railway supplies, and as factory engineer designing and supervising the installation of mechanical equipment of all kinds in modern manufacturing plant, desires position as works engineer or assistant in manufacturing plant or as mechanical engineer, with engineering firm designing and installing industrial plants. Salary, $2700 to $3000. Location, Chicago or vicinity preferred. F-154.

ELECTRICAL AND MECHANICAL ENGINEER, married, nine years' experience on power-station operation and construction work. Has been in charge of large hydroelectric stations, high-voltage transmission system and sub-stations. Desires executive position with large power or holding company. F-155.

ASSISTANT ENGINEER. Junior member, technical graduate 1914, age 25, married, in Class IV of draft in present position since graduation, thorough drafting and engineering experience, desires position of responsibility in small to medium-sized industrial plant preferably in New England, manufacturing standardized product. F-156.

MECHANICAL ENGINEER desires to associate with consultant or industrial firm as expert on tools and production methods. Available for two or three days a week only, as balance of time is being devoted to development and manufacture of standard shop appliances for munitions plants. Location, Philadelphia. F-157.

EXECUTIVE. Junior member, graduate of Massachusetts Institute of Technology, 35 years of age, ten years' continuous service with present concern, advancing from draftsman to superintendent, desires opportunity for larger service. Experienced in shop management, embracing tool and machine design, stock and toolroom organization, planning and routing work, handling men and producing, shop accounting, and modern methods of payment. A student of, and believer in, scientific management, and anxious to develop along such lines. Minimum salary, $4500. Available after two weeks' notice. F-158.

PRODUCTION MANAGER OR WORKS MANAGER. Member graduate mechanical engineer, several years' experience in the manufacture of transmission and special machinery, and especially familiar with the planning and organizing of plants for intensive production of duplicate parts. Now doing Government work but will be available about June 15. Best of references. F-159.

MECHANICAL ENGINEER with executive ability. Technical graduate, 13 years' experience in the design, construction and operation of power plants and general manufacturing machinery. Well experienced in the production and application of electricity in manufacturing plants. Specializes in operation of plants and manufacturing equipment including the economical combustion of fuel. F-160.

EXPERIMENTAL ENGINEER, technical graduate, five years' designing experience; at present experimental engineer with large manufacturing concern. Munition work preferred. F-161.

SUPERINTENDENT OR PRODUCTION MANAGER. Member, technical graduate, age 36, strong disciplinarian and successful handler of men; well up on efficiency, rate setting, cost accounting and modern shop management, desires new connections with company operating a foundry or machine shop or both. Present salary, $4000 per year. F-162.

WORKS MANAGER, at present employed by large concern in charge of factory. Experienced in manufacture of machinery and details of factory management, also power-plant operation. Energetic, good personality and best of reference covering more than 15 years with present employers. Technical education. Age 47. Desires change to increase possibilities. Prefers location near New York. F-163.

MECHANICAL ENGINEER. Member, American, age 36, technical education, married. Expert designer of complex appliances and special machinery; 16 years' practical experience in modern drafting-room methods, shop practices, manufacture, erection and tests. Desires position as engineer, head of drafting department or similar position of responsibility. Detailed information on request. F-164.

MECHANICAL ENGINEER AND EXECUTIVE with 12 years' experience in drafting, elevator and power-plant construction, manufacturing and sales work, desires new connections with a growing concern requiring the services of an executive with initiative and aggressiveness. Location no object. Minimum salary, $2300. F-165.

EXECUTIVE. Graduate mechanical engineer, American, with unusually broad business and engineering experience in this country and in Europe. Can handle men and coordinate work of different departments. Particularly successful in adjusting contract disputes in matters involving expert technical knowledge. Acquainted with modern production methods, and understands principles of accounting. Writes clear, forcible English. Can fill acceptably any responsible position in a manufacturing establishment. Would make exceptionally good assistant to chief executive of very large and complicated business. Worth an interview at least. F-166.

MECHANICAL ENGINEER, married, specialized in power-plant equipment, design and testing of marine apparatus; also condensers and spray-cooling systems. Had charge of sales office. F-167.

ASSISTANT TO EXECUTIVE. Age 33, technical graduate of Yale. Eleven years' experience along several lines of manufacture. Has held positions of draftsman, assistant engineer, surveyor, engineer in charge of improvements and reconstruction, plant manager and assistant to president. Good knowledge of industrial equipment and purchasing; competent to assume responsibility and handle detail work as well as correspondence as an executive. Interested worker. Desires to locate with growing company offering executive future and permanent position. At present engaged. East or Middle West. F-168.

MECHANICAL ENGINEER. Industrial and power-plant experience. Desires responsible position. F-169.

MECHANICAL ENGINEER. Member, American, age 48, experienced in mill designing and operating, hydraulic power development and water storage, now employed, desires change. Capable manager and executive officer. F-170.

MECHANICAL ELECTRICAL ENGINEER, Columbia graduate, sales manager or superintendent. At present employed as manager of a very large concern. Experience in internal-combustion engines, gas producers, power installations, foundry and machine-shop practice and marine power plants. Unusual business and technical training. Fully conversant with French, Italian and Spanish. Minimum salary to start, $4,000. F-171.

MECHANICAL ENGINEER, member, graduate, experienced in small parts manufacture and now engaged as production engineer on Government work, desires executive position in similar lines. Available in 30 days. F-172.

EXECUTIVE, MECHANICAL, and CHEMICAL ENGINEER, 39 years of age, married. Technical graduate, two years' experience abroad and 12 years in U. S. Designing, erecting and operating, cement plants, chemical plants and glass work with labor-saving machinery. Can control analytical work on raw materials and finished products such as cement and glass. Able to handle tactfully executives and employees. Employed but desires responsible permanent position in a northern state. Minimum salary $3,000. F-173.

MECHANICAL ENGINEER. American, with experience on Diesel and steam engines, also boilers, tanks and stacks. At present assistant chief draftsman with a company building oil engines. Desires executive position with a company who could use man with above experience. F-174.

MECHANICAL ENGINEER, member, age 34, technical graduate with 12 years' experience covering steam-power plant design, heating and ventilation, general test and efficiency work, machine design, construction, estimating. Can work into several lines on account of broad knowledge and thorough technical ability to develop new lines of work. At present employed in capacity of consulting engineer for large oil refinery nearing completion. F-175.

CHIEF INSPECTOR, thoroughly familiar with airplane engine manufacture and testing. Technical graduate, age 38, member S.A.E. and junior member A.S.M.E. since 1906. Experienced in shop, office and sales methods gained in the engineering departments of shipyards, as assistant superintendent of a manufacturing plant, and sales manager of a machinery house in New York. Location, Middle West or Pacific Coast. Available at once. F-176.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

National Foreign Trade Convention

THE fifth convention of the National Foreign Trade Council was held in Cincinnati, Ohio, on April 18, 19 and 20. Delegates to the number of about twelve hundred gathered there, representing a large number of manufacturers, exporters, shippers, banks, the Government, chambers of commerce, and various organizations. Mr. E. A. Muller, of Cincinnati, was appointed by President Main to represent The American Society of Mechanical Engineers.

Possibilities of the Webb-Pomerene Bill

In an address during the meeting Edwin M. Herr, Mem. Am. Soc. M. E., president of the Westinghouse Electric & Mfg. Co., spoke of the importance of coöperation in export trade. He said that we are facing as serious and critical a situation in our foreign trade, especially our foreign trade in manufactured products, as the nation faced at the sinking of the *Lusitania*, and are doing almost as little toward real preparation for the proper development of this trade as did we as a nation in preparation for the terrible war in which we are now engaged. A step of great importance to exporters is the passage of the long-delayed Webb-Pomerene bill, which legalizes combinations for export trade and permits manufacturers of a given district to organize and to work in coöperation in order to meet the far-reaching plans of our competitors in foreign fields.

Treating this same subject was a paper by George H. Charls, of the American Rolling Mill Co., presenting a plan for coöperation under the provisions of the Webb-Pomerene bill. This involved the organization of a company with a business management that would exert every effort to secure the coöperation of schools and colleges in introducing practical export trade studies, and in teaching the languages most useful in the fields of American foreign-trade enterprise. This company would adopt well-established selling methods for its organization, which would comprise the compilation of addresses of American representatives in foreign fields, lists of foreign houses, the securing of data and price quotations from the various manufacturers, the establishment of individual departments to handle the sale of different products and organizations, of a clearing house on credits, shipping rates, etc.

Magnitude of the Country's Industries

E. A. S. Clarke, of the Lackawanna Steel Company, quoted figures showing the remarkable increase in iron and steel output in 1916 over 1915, over $33\frac{1}{3}$ per cent. The plate-making capacity of the country has been nearly doubled, standing now at about 6,000,000 tons per year, the equivalent of 18,000,000 dead-weight tons of ships, with approximately 1,000,000 tons of additional capacity under construction which, it is thought, will be in operation before the end of the year.

Other speakers referred to marked increase in production in other fields.

The production of the American potash industry has increased from an annual output of 970 tons to 42,000 tons a year in the short space of two years.

The amount of both the crude and refined oil produced has been enormously increased during the last year. The extent of the war demand for these supplies is indicated by the fact that in 1913 exports of gasoline to our allies totaled 29,000,000 gal. and in 1917 they amounted to 300,000,000 gal. Lubricating oil shows similar increase of export, the total of 103,000,000 gal. in 1913 mounting to 200,000,000 gal. in 1917. Naphtha and gasoline export records show the total of 1913 to have been 188,000,000 against some 400,000,000 gal. in 1917.

It is estimated that there are 300,000 automobiles in use by the armies on all fronts. Of these our allies have bought 45,308 from America during the last three years compared with only 410 in the two years preceding the war. Last year American export trade in automobiles exceeded \$88,000,000 for 65,792 passenger cars and 14,347 trucks—most of the latter going to the countries at war. The United States Army has bought and ordered some thirty thousand motor trucks, and requirements are in sight for from ten to fifteen thousand more.

In a paper on The Influence of the Demobilization of War Industries upon World Commerce by Charles M. Muchnic, vice-president of the American Locomotive Sales Corporation, some indication of the magnitude of our war industries is obtained:

On April 6, 1918, our ordnance program included the purchase of 23,000,000 hand grenades, 725,000 automatic pistols, 250,000 revolvers, 23,000,000 projectiles for heavy artillery, 427,246,000 lb. of explosives, 240,000 machine guns and 2,484,000 rifles.

When war was declared, 123 naval vessels were building or authorized; contracts have been placed since for 949 vessels.

In February the Director-General of Military Railways placed orders for supplies valued at \$142,000,000 and with an aggregate weight of 754,000 long tons; the General Engineer Depot to February 1 issued 9500 orders for material valued at \$202,000,000.

Emphasizing more particularly the need for educational preparation for foreign service, Glen L. Swiggett, of the United States Bureau of Education, presented an extremely valuable paper in which he not only outlined the requirements of preparatory courses for service in foreign trade and suggested a curriculum, but summarized the courses which are now offered by schools and colleges throughout the country according to cities and states.

Cotton Convention and Exposition

An important happening during the first week in May in New York City was the convention of the National Association of Cotton Manufacturers and the American Cotton Manufacturers' Association. At the same time an exposition was held at the Grand Central Palace.

The subjects discussed covered an unusually wide range, being devoted to matters in the field of finance, economics,

home and [illegible] trade as well as technical matters in the broad meaning of the word.

One of the most interesting meetings was devoted to a group discussion of research as an aid to industrial efficiency.

Dr. George E. Hale spoke of the work of the National Research Council, Dr. Edward R. Wardlem, of the Mellon Institute of Pittsburgh, on Science and Industry, while Dr. C. E. K. Mees presented a paper on Planning the Research Laboratory for an Industry.

The dye exhibits at the Sixth National Show were a striking proof of the adaptability of American industry to new conditions. Less than four years ago this country relied practically exclusively on importations from Germany for its dyes. Now, domestic needs are not only fully covered but a comfortable export trade in dyes is being built up.

Probably the most difficult problem which has confronted American dye makers has been the development of a supply of intermediates. The coal-tar industry was in such a crude state in this country that when war cut off foreign supplies the country lacked not only the dyes themselves but also the materials from which they are directly produced.

Now practically all of the principal dye makers are also producing intermediates, some on a very large scale. This growth of the production of intermediates has been materially assisted by direct war demands, as several of these intermediates are first by-products or produced from by-products of munitions manufacture. On the other hand, however, war demands have absorbed some of the raw materials of dye manufacture to such an extent as to cripple the production of the dyes. This is especially true of the toluine group of colors, hampered by the fact that the entire production of toluol is absorbed by the more important high-explosives production.

The greatest lesson of the show was, however, in indicating the great possibilities of peace production in America under conditions which may be expected after the termination of the war, provided, of course, the industry is not then hampered by outside interferences.

United States Railroad Equipment Standardization

The United States Railroad Administration has announced the placing of orders for 100,000 freight cars to be built to its standard specifications, and 1025 locomotives, also of its standard types.

The statement issued regarding the locomotives is as follows: "The six standard types of locomotives, two sizes of each class, are expected eventually to supersede the many miscellaneous types and varieties of locomotives now in service, embracing engines built according to five hundred or more varying specifications. This is the first time that any real forward step has been taken looking to the wide standardization of locomotive engines."

A somewhat similar announcement was made with respect to the car orders, saying, among other things, that "the adoption of these standard types, it is believed, will eventually substitute a few scientifically worked-out designs for the numerous miscellaneous varieties of the cars representing probably more than a thousand different old styles and specifications now in use, the accumulation of the past."

The policy has been received not without criticism on the part of the technical press. Thus, the *Railway Age* (May 10, 1918) points out that the adoption of these standards has not been made for the purpose of saving time, but indicates definite tendencies to standardize thoroughly the entire motive power and car equipment of the railroads.

The tentative specifications of the standard locomotive were published in the *Railway Age Gazette* for April 19, 1918.

In the main, it appears to have been the desire of the committee designing the locomotives to provide types which will best meet average conditions.

The locomotives are all designed to traverse 19-deg. curves and grades of 2 per cent. The clearance limitations are practically alike, the overall height being 15 ft., with the exception of the heavy Santa Fe and the 2-8-8-2 Mallet, which have height clearance of 15 ft. 9 in. The width of cylinders is also the same for all designs, with the same exceptions as above.

The freight locomotives of the Mikado, Santa Fe and Mallet types cover fairly well the range of tractive efforts for that kind of service, comprising six types from 54,600 lb. to 106,000 lb., and, in addition, the boiler factors of the heavy Mikado and two Santa Fe-type locomotives are sufficiently high to permit increased tractive effort by increasing the boiler pressure.

Fear has been expressed that there may be difficulties, particularly around terminals at low bridges, also on some tunnels. Thus the Hoosac tunnel of the Boston & Maine has a height clearance of 14 ft. 8 in., which will prevent any of the standard locomotives passing through the tunnel.

The tentative specifications for the standard steel-sheathed box car have been published in *Railway Age* for April 12, 1918. In its basic features it is the same as other standard box cars, and is to be carried on the standard 50-ton truck.

The most interesting details refer, of course, to the superstructure. In this respect the designs called for an 1/8-in. steel sheathing with a 13/16-in. lining at the sides and ends, and a steel roof of 3/32-in. plates. As regards the side framing, it comprises six pressed-steel posts on each side of the car made from 1/4-in. plates. These are 18-in. wide and 3 1/2-in. deep. In addition to these there are eight 3-in. x 3 1/2-in. wooden side posts to which is nailed the inside lining. The end posts for the plain end construction are pressed from 1/4-in. plate and are 7 3/4 in. wide by 3 3/4 in. deep. The corner posts are of wood. The side plates are 4-in., 10.3-lb. Z-bars, to which are riveted the side sheathing and the roof sheets.

Two designs of roof are permitted.

The tentative specifications for the general type of United States standard cars are published in the *Railway Age* for March 29 and April 5. These cover seven types of bodies for box, hopper and gondola cars and three types of trucks. They are quite extensive and cannot be reproduced here because of lack of space.

War Department Bureau Created to Pass Upon Plans of Inventors

The following statement is authorized by the War Department:

In order to secure prompt and thorough investigation of inventions submitted to the War Department, an "Inventions Section" has been created as an agency within the General Staff. All inventions of a mechanical, electrical, or chemical nature submitted to the War Department for inspection, test, or sale are now considered by this section.

Inventions may be sent by mail or may be submitted in person, accompanied by written descriptions or drawings. They go first to an examining board having technical knowledge of the classes of inventions they handle, whose investigations determine whether the inventions have merit. Those with merit are referred to the Advisory Board, which determines in

each case whether it should be put in the hands of some of the numerous testing and developing agencies, or if it should go to one of the staff or supply departments for test and consideration of its adoption, and final acquirement of title if such action is desirable.

When completed the board will have twelve to fifteen members to cover fully all of the various technical problems which may come before it.

Any persons desiring to submit an invention for consideration, test, sale, or development should do so by letter, giving in order the following information: Name and object of the invention; any claim for superiority or novelty; any results obtained by actual experiment; whether the invention is patented; whether remuneration is expected; whether the invention has been before any other agency; whether the writer is owner or agent; the number of inclosures with the letter. A written description and sketches or drawings of sufficient detail to afford a full understanding of the cases should also be submitted. Should the invention be an explosive or other chemical combination, the ingredients and processes of mixture should be stated.

The Inventions Section will not bear the expense of preparation of drawings and descriptions, nor advance funds for personal or traveling expenses of inventors.

Any matter submitted will be treated as confidential. The inventor will be notified of each step taken during the investigation of his invention. All communications should be addressed: Inventions Section, General Staff, Army War College, Washington, D. C. (*Official Bulletin*, May 13, 1918, p. 3)

Testing the Relative Strengths of Riveted and Welded Parts of a Ship's Hull

The purposes and possible benefits of the ship-welding test being conducted by the Emergency Fleet Corporation at the Central Shipbuilding plant, at Newark, N. J., under the direction of Arthur J. Mason, are outlined in a report made to Charles Piez, vice-president of the corporation, by Mr. Mason. The report follows:

The committee of which Prof. C. A. Adams is chairman has been enlarged, as instructed, and is active in bringing to bear all the knowledge and apparatus available, about which, no doubt, reports will come to you directly from time to time. I am a member of that committee and continue in active touch with it and rely on it for technical knowledge.

Electric welding in its various phases has for years been employed in shipyards and in the arts generally, but for a number of reasons the work has been confined to odd jobs and repairs. The proposal to extend its use to the major part of ship construction has met with gratifying approval from the shipbuilder. It remains for us through this large test to demonstrate its economy in time and money and its adequacy to build a stanch ship.

The purpose of this test is to demonstrate these advantages, to do it in such a way that all may see and contribute, and finally to test the structure itself so completely that there will follow a heart-whole and unanimous belief in the method.

The test itself will take the form of building part of a hull at the Federal Shipbuilding plant, Newark, N. J.

It has been necessary to design a ship to suit the material available, without encroaching on that needed for the regular ship construction at the plant. This has been done. The hull will have the outline, dimensions and strength conforming to the ships the Federal company is building.

It has been thought best to conduct the work at a site apart from the shipways, so as not to interfere with that program.

A 10,000-ton ship, costing $2,000,000, now costs but $70,000 to rivet. It must be plain that if electric welding only promises to modify this amount, no very substantial gain offers.

Splendid benefits we all feel do offer themselves in the possible change in the whole régime of shipbuilding. Our test has in view abolishing, or greatly diminishing—

1 The railroad journey from rolling mill to fabricating plant, when the latter is not at the shipyard
2 The template-makers' work
3 The markers' work
4 The punching
5 Much of the work of the fitters and bolters, who flog and pull the pieces to fit on the ways.

There lies in the above items an excellent likelihood to save a month's time in construction and a saving of no less than $40 a ton in the cost of steel structure, at least $100,000 a hull on a 10,000-ton vessel.

Briefly the program is to assemble a hull rapidly by spot welding, tacking the ship together much as a tailor bastes his work in assembling a suit of clothes. The structure then becomes a house favorable for work in all weather and at night in which the completion of the ship may go on.

After the material is thus assembled and fastened with spot welds so that it is sufficiently strong to hold its shape, the work is completed by arc-welding all seams to insure strength and render the work watertight. Roughly we expect the spot welds to be about ten inches apart.

The severe tests of strength contemplated needed about 300 piles.

One-quarter of the structure will be riveted; the other three-fourths welded so that the tests of strength will afford a basis of comparison.

Electric welding offers a great field for lightening a ship. In this design various views of this opportunity will be tried out. The field here is very great—ultimately ten per cent of the steel may be eliminated.

Only a fifth of the men on a hull are riveters. The spot-weld yoke will forthwith pull the parts to place with much more vigorous agency than flogging and pulling to place by numerous bolts, now done by the other four-fifths.

The problems of fitting in place the parts of a hull are almost wholly problems arising out of the necessity to make a number of little holes in a plate made by one man at one time and place fit a number of little holes made by another man at another time and another place.

Once all holes are left out of the material, all parts fit. The creeping and kindred problems so perplexing to the shipbuilder disappear. Every plate becomes a closer. Every plate justifies itself.

An adequate system of testing the work when done is under consideration.

The primary test will consist of filling the hull with water and shifting the points of support under continual and close scrutiny, as one-quarter of the whole will be riveted in the normal manner. There will be always a gage of comparison with that portion which is welded. Likewise there will be a chance for comparison of the two forms when subjected to abuse, by bumping with rams and in various other ways. (*Emergency Fleet News*, April 29, 1918, p. 11)

Interest in Use of Steam Meters in England

Shortly after the inauguration of the Government department of scientific and industrial research (about 18 months ago) it was decided to form a society, to be called The Brad-

[illegible] Research to [illegible] mechanical and electrical engineers in the [illegible] largely became subscribers. A committee of representatives of these firms was formed, with Mr. Frank Wigglesworth, of Messrs. Frank Wigglesworth & Co. (Ltd.), engineers, [illegible] Wood, Shipley, as honorable secretary. From a number of subjects submitted for inquiry the first one selected was Flow of Steam in Pipes, with Special Reference to Steam Meters. The Government advisory council was approached with a request for assistance in the form of a grant, and several interviews have taken place with the authorities in London, whose sanction to the project has been given on the understanding that half of the cost of the research will be subscribed locally.

The need for a reliable steam meter is very great, especially where steam is used for heating and boiling, as in dye works, bleaching works, chemical works, soap works, paper mills, etc. It is well known that a large proportion of the steam is wasted in ways which cannot easily be detected, and which have come to be regarded as inevitable. A reasonably accurate steam meter would help materially to reduce these losses. During the last ten years several forms of meter have been brought out, and have met with more or less success. They are all, however, of American or German origin, and hitherto nothing has been done in Great Britain either in the way of research or in the manufacture of an instrument of British origin. The foregoing is from the *Yorkshire Observer* of April 5, 1918, in regard to a report to be issued by the Bradford Association for Engineering Research, on the Flow of Steam in Pipes, with Special Reference to Steam Meters. (*Commercial Reports*, no. 100, April 29, 1918, p. 389)

Pitch as a Steam-Boiler Fuel

Pitch is composed chiefly of free carbon and of hydrocarbons which become volatile on heating above 400 deg. cent. Under correct conditions it can be burned completely to carbon dioxide and water vapor. The elementary analysis of pitch shows it to contain from 90 to 94 per cent of carbon and from 4 to 4½ per cent of hydrogen. The "approximate" analysis, however, gives a better indication of its composition and of difficulties that may be expected when burning it upon a commercial scale, for when it is raised to a red heat in a platinum crucible two-thirds of it passes off as volatile matter, and only one third remains behind in the crucible in the form of pitch coke. When tested in the bomb type of calorimeter pitch shows a calorific value of 15,600 B.t.u. gross or 15,000 B.t.u. net; that is, it possesses a heat value equal to that of the best Welsh steam coal. If supplied with sufficient oxygen and raised to a temperature sufficiently high to secure complete combustion it is therefore a valuable fuel, and the problem of its efficient utilization under steam boilers resolves itself into one of providing the necessary conditions inside the boiler furnace.

Two difficulties are met with when burning pitch under industrial conditions in ordinary grates and furnaces, both due to certain physical characteristics of the fuel. In the first place, it softens at a comparatively low temperature and passes into the semi-fluid state by almost imperceptible stages. In the second, the hydrocarbon gases which form two-thirds of the weight of the fuel when heated come off with great rapidity when once the molten pitch has attained the temperature necessary for gasification. At a moment, therefore, when a great increase in the air supply is necessary, the molten pitch is flowing into the air spaces between the firebars of the furnace, and is closing these, with disastrous results for the proper combustion of the evolved gases.

As regards trials of pitch for steam-raising purposes carried out in London, the fuel expert of the London Coke Committee, Mr. E. W. L. Nicol, soon after the outbreak of the war began to experiment with this use of pitch, since it was seen that if a mixture of coke and pitch could be burned with a fair measure of efficiency under boilers, a better market would be created for these two by-products of the gas-making and tar-distilling industries, and incidentally the demand for ordinary coal would be reduced. A special type of firebar was designed by Mr. Nicol for the purpose, its chief feature being that it contained a channeled passage leading to a spoon-shaped trough, in which the molten pitch collected and remained while the volatile gases were distilled. Steam jets were employed with this bar in order to supply the heated air necessary to mix with and consume the large volumes of hydrocarbon gas produced as the solid pitch fed on the flat and cooler end of the bar melted and flowed down into the cavity at the center, where the heat of the surrounding incandescent fuel gasified it. These "pitch bars" could be sandwiched, in any number required, between the ordinary bars of the furnace grate, the latter being removed to make place for them. The pitch coke that collected in the center trough of the bars, after the gases were distilled, was cleared out from time to time and burned at the rear of the furnace on ordinary firebars. The trials of these special pitch bars were suspended in 1917 owing to the increase in the price of pitch in London, but so far as they went they proved that pitch can be burned with coke in this way without excessive nuisance from smoke.

Among new forms of "atomizer" for very thick and viscous liquid fuels, patent No. 101444 of 1916, granted to H. Bolling, of Christiania, describes a method of melting the pitch by aid of superheated steam, while German patent No. 300301 of 1916, granted to H. Sieger, describes a more complicated form of gas-heated vaporizer for liquid fuels, in which the principle of flameless combustion is employed to gasify the fuel before it is injected into the combustion chamber of the furnace or boiler. Another German patent, No. 299864 of 1915, makes use of an electric resistance coil for preheating, and of a pilot jet of light oil for ignition purposes. All these devices, of course with some modification, might be applied to the atomization of pitch, and lest it be thought that only foreign engineers are devoting their attention to the problem, it may be stated that English inventors are already at work upon it, and that very shortly an English design of liquid fuel burner for use with pitch will be placed upon the market. (*The Times Engineering Supplement*, no. 522, April 26, 1918, p. 84)

Products Derived From Corn Cobs

In a paper read before the New York section of the American Chemical Association at its regular meeting last Friday night, Dr. F. B. LaForge of the Bureau of Chemistry said that with the American corn crop estimated at 3,000,000,000 bu., which means probably about the same amount of corn cobs now going to waste, the United States Bureau of Chemistry has discovered practical and probably commercial methods whereby 37½ per cent of their substance can be converted into glucose, 30 per cent into usable mucilage, and 5 per cent into xylose, in addition to much new baking-powder material and a large quantity of acetic acid, with probably other valuable by-products yet to be discovered.

According to Dr. LaForge, there are four principal materials which may be prepared successfully from corn cobs;

about 30 per cent of a gum resembling dextrine but composed largely of polymerized xylose, instead of glucose, as in the case of dextrine. This material should be useful as an adhesive in the paper-box industry, for bill posting, wall papering, labeling, etc. It would be extremely cheap, and as far as its sticking qualities are concerned, it is probably about the equal of the dextrine preparations now commonly used. Its use would make possible an enormous saving of the foodstuffs now used in making dextrine and other starch preparations.

From 5 to 6 per cent of the pentose sugar xylose is another product. This sugar has been up to now a comparatively rare substance, but one and possibly two uses for it have been tried out or are being worked out and will be described later.

Acetic acid is obtained in the preparation of xylose in amounts which, at its present price, would be a very great source of profit in working up large amounts of cobs and at all times would be an important by-product. (*Journal of Commerce*, May 13, 1918, pp. 15 and 17)

Rochester Plan for Supplying Shipyard Labor

As the result of a conference between the Merchants' Association and representatives of the New York shipyards, the idea underlying the "Rochester Plan" for supplying shipyard labor may be adopted in New York. The essential feature of this plan is a central employment bureau created and operated by all the important Rochester, N. Y., industries, through which they secure all their labor. The central bureau becomes a labor-recruiting organization for all Rochester factories and endeavors to prevent other cities from inducing Rochester workmen to leave Rochester. It guarantees that the most essential Rochester plants will be furnished with the necessary skilled workmen even if that necessitates a voluntary draft on other factories, and it seeks to make labor conditions in Rochester plants such that the workmen will be properly treated, satisfied and efficient. In other words, Rochester has endeavored to place the entire community squarely behind the plants working on war orders.

It was the opinion of most of those present at the conference that the "Rochester Plan" is essentially a community plan which could not be adopted successfully in a large and complex metropolitan district, but that the underlying idea of the plan, namely, that of centralized effort to increase the shipyard labor force and to adapt mechanics to shipyard work, is possible and desirable.

In essence the "Rochester Plan" consists of a coöperative employment bureau organized, financed and operated by the important industrial plants of the city, and in charge of a very high-grade man having extensive experience in industrial-employment problems. The chief function of this employment agency of the manufacturers is to obtain a sufficient number of workmen to meet the requirements of all factories of the city. All additional workmen of plants operating under this agency are secured through it. In obtaining labor, the principle is followed that the demands of plants working on Government war supplies must be met first, even if this means taking skilled men from those less-essential plants supporting the Central Employment Bureau. In fact, there has already been a voluntary industrial draft to obtain certain skilled workmen needed by the plants operated for the Government.

The Central Employment Bureau has not displaced the regular employment agencies, but works through them as much as possible. It also seeks to bring workmen to Rochester from communities where a supply of skilled labor is available. In doing this it represents industrial Rochester rather than individual plants. It does not stop at merely bringing the workmen to the city, but it distributes them to the various plants according to their needs and to the type of workmen, aids in getting the workmen properly housed in a district near the plants, and in general endeavors to make the workmen contented and satisfied with Rochester.

So called "stealing the labor" is eliminated. However, it is realized that much of the additional labor needed by the war industries of Rochester is already there and must be shifted from less-essential plants. The Central Employment Bureau has proved to be a valuable agency for transferring labor from industry to industry. The industry which must lose its labor to some extent to more essential plants is aided in diluting its remaining labor and thus in continuing efficient production, while at the same time it is protected from losing a proportion of its labor force so large that it becomes impossible to dilute the remainder successfully. On the other hand, through the Central Employment Bureau the essential plants are constantly studying the problems of training inexperienced workmen and diluting their own skilled force so as to expand production with the least possible harm to the other industries of the city. (*Journal of Commerce*, May 3, 1918, p. 3)

Pig-Iron Interests Form Association

The production of pig iron is so far short of the heavy demand for it that preference has had to be given in making allotments to certain concerns holding urgent Government contracts. There has also been some controversy as to what constitutes the base price for determining the differentials, and there has also been considerable controversy between the trade and the War Industries Board on the subject of the right of sellers to collect commissions from consumers.

To enable these differences to be brought to the attention of the Washington authorities in a representative and official way, and to arrive at a settlement of all such questions as may arise between the Government and the trade, an organization known as the Merchant Pig Iron Distributers' Association has been organized at a conference held in Philadelphia.

The president of the new association is W. S. Pilling, of Philadelphia, and the secretary is W. W. Hearne, of the same city. The membership is not yet complete, but it will include all representatives of all the leading distributers of pig iron in the United States. It has been felt by members of the industry that they should be entitled to greater consideration when matters of vital importance to the trade were decided at Washington. (*Journal of Commerce*, April 23, 1918, p. 3)

The spring meeting of the National Machine Tool Builders' Association was held at Atlantic City, May 16 and 17. The meeting was devoted mainly to subjects relating to the war, the leading feature being an address by Isaac F. Marcosson, war correspondent of the *Saturday Evening Post*, on the Business of War. Addresses more technical in nature were given by H. W. Dunbar, of the Norton Grinding Company, on Safety Devices on Machine Tools, by H. E. Miles, on Women in Industry, and one by George Merryweather, relating to work of the Machine Tool Section of the War Industries Board.

Of the business transacted, the most important dealt with the production of heavy machine tools such as required for the work of the Ordnance Department, both with regard to the design of the machines and the apportionment of the tools in a way to secure the maximum production necessary to meet the present emergency of the Government.

U. S. BUREAU OF STANDARDS

COMPARATIVE TESTS OF CHEMICAL GLASSWARE, Percy H. Walker and F. W. Smither. Beakers of Kavalier glass, and beakers and flasks of Macbeth Evans Glass Co., Pyrex, Jena, Nonsol, Fry and Libbey glasses were tested for chemical composition, coefficient of expansion, refractive index, strain, behavior on repeated evaporation, resistance to heat and mechanical shock, and to solution in a variety of chemical reagents.

No conclusions as to the relative values of the different wares can be drawn from the chemical analyses, though these analyses may be useful by enabling the chemist to choose a glass which will yield no objectionable ingredient to the solutions used in any particular piece of work. The coefficient of expansion of all the glasses is low and is unusually so in the Pyrex ware. All the ware shows more or less strain, but it was disappointing to find that no information as to liability to break under sudden changes in temperature or mechanical shock could be obtained by an examination for strain. All the ware tested showed good resistance to repeated evaporation of a salt solution. While the heat and mechanical shock tests were performed on too small a number of pieces to justify positive conclusions, they indicated that the Kavalier and M. E. G. Co. ware are less resistant than Jena, Nonsol, and Fry wares, the Libbey somewhat more resistant and the Pyrex ware distinctly more resistant. The Kavalier ware is unsatisfactory as regards solubility in water; all the other wares appear satisfactory in this respect. All the ware is resistant to acids. Kavalier is least resistant to carbonated alkalies, Pyrex more resistant than Kavalier but less resistant than the others. Kavalier and M. E. G. Co. wares are more resistant to boiling caustic alkaline solutions than the others but the differences are not great. All the glasses are much attacked by evaporating caustic alkalies. Ammonia water has about the same effect as mixtures of ammonium chloride and sulphide. The authors are of the opinion that considering all the tests each of the American wares is superior to the Kavalier and equal or superior to the Jena ware. (*Technologic Papers of the Bureau of Standards*, no. 107)

EFFECT OF THE SIZE OF GROG IN FIRECLAY BODIES, F. A. Kirkpatrick, Assistant Physicist. In those industries which use crushed and ground raw materials in forming bodies by means of a cementing action of some sort the size of the particles plays a most important rôle. This may be in many instances the main factor controlling the desired properties in the body. This is nowhere more true than in the ceramic industries, where in compounding bodies the manufacturer is compelled to use materials from the size of pebbles down to the dispersoid and emulsoid (colloidal) states. All present evidence tends to show that in disperse systems the size of particles which we can not now measure has as much effect upon the properties of certain materials as have the larger sizes which we are able to measure. In no other way is it possible to account for the great differences in cementing power exhibited by fine-grained bond clays and other fine-grained materials. In practice the cementing action takes place at temperatures from zero to that of the electric arc, depending upon the nature of the process, and is due to many different chemical reactions. In the present work the bonding power of mixtures composed of raw clay and calcined clay is determined after these bodies have been heated to 110 deg. cent. and to 1250 deg. and 1300 deg. cent.

The control of the strength of raw fireclay bodies is a difficult matter into which enter a number of factors. Those which are directly connected with the size of grog are size of the body, cracks formed in drying, density or porosity, and size of grain of the clay.

If the grog is too large for the size of body used, the conditions of bond are different than for smaller grog. Small cracks may or may not form in drying. The general rule in ceramic bodies is that strength increases with decrease of porosity, but this factor may be overruled by others. In series 4 of the tests carried out, however, the rule holds. As shown in connection with series 5 and 7 the size of grain of the bond clay also affects the strength of the body. In regard to the grog, aside from other considerations, the following condition is necessary for highest strength. The mixture of sizes must be such that the smaller particles fill the voids between the larger, giving maximum density. The proper proportions may be predicted qualitatively from the ratio of sizes, but can be determined accurately only by experiment.

The strongest raw bodies were those in series 4 and 7. In series 4 these had the following limits of grog composition: 25 to $66\frac{2}{3}$ per cent, 20 to 40 grog; 0 to 25 per cent, 40 to 80 grog; and $33\frac{1}{3}$ to $66\frac{2}{3}$ per cent, 80 to dust grog. In series 7 the strongest bodies were those containing the greatest percentage of 80 to dust grog.

The control of strength in the burned state proved to be not at all difficult. For all bodies used the modulus of rupture was found to increase with increase of surface factor. The relation was represented by means of straight lines except that the lower portions of some of the curves representing large-sized grog were of parabolic form. The rate of increase of strength increased with the temperature of burning, due to the more rapid rate of solution of the finer particles at the higher temperatures. The porosity at cone 12 varied much the same as in the raw bodies and had little relation to strength. The strongest bodies were those in series 4 (20 to dust grog). No relation was found between strength in the raw state and in the burned state.

In the quenching tests from 600 deg. cent. and 1000 deg. cent., mixtures of the larger sizes of grog gave the more resistant bodies. (*Technologic Papers of the Bureau of Standards*, no. 104)

National Research Council as a Permanent Body

The National Research Council was organized in 1916 at the request of the President by the National Academy of Sciences, under its congressional charter, as a measure of national preparedness. The work accomplished by the council has demonstrated its capacity for larger service, and the National Academy is now requested by executive order of President Wilson to perpetuate the National Research Council, the main duties of which shall be as follows:

1 In general, to stimulate research in the mathematical, physical, and biological sciences, and in the application of these sciences to engineering, agriculture, medicine, and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare;

2 To survey the larger possibilities of science, to formulate comprehensive projects of research, and to develop effective means of utilizing the scientific and technical resources of the country for dealing with these projects. (*Official Bulletin*, May 14, 1918, p. 1)

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Tools, Munitions, Varia

Aeronautics

Aviation and the War, C. F. Lee. *Journal of the Washington Academy of Sciences*, vol. 8, no. 8, April 19, 1918, pp. 225-232. Discussion of the training of aviators, with special reference to "stunt" and formation flying; also some remarks on the classification of machines.

The Sopwith Triplane. *Flight*, no. 484 (vol. 10, no. 14), April 4, 1918, pp. 361-365, illustrated.

The Effect of an Airplane Rudder in Flight, Karl H. White. *Aviation and Aeronautical Engineering*, vol. 4, no. 7, May 1, 1918, pp. 448-449, 4 figs. Describes methods for finding the moments about the center of gravity of airplanes of different length due to rudders of different aspect ratios under varying angles of deviation. The results are expressed in the form of tables and curves.

The Gallaudet Airscrew Propulsion Described. *Aviation and Aeronautical Engineering*, vol. 4, no. 7, May 1, 1918, pp. 454-456, 4 figs. Description of the construction of an airplane fitted with a pusher propeller without using an attachment of the tail planes by means of outriggers or tail booms, the presence of which generates a certain amount of parasite resistance: taken mainly from a United States patent.

Defects in Steel Ingots and Forgings, S. W. Werner and Gordon Spencer. *Iron and Steel of Canada*, vol. 1, no. 3, April 1918, pp. 110-116, 13 figs.

La Fabrication des Briques de Silice, H. LeChatelier and B. Bogitch. *Bulletin et Comptes Rendus Mensuels de la Société de l'Industrie Minérale,* Tome 12, 3rd issue of 1917, pp. 49-97, 14 figs. Data on the manufacture of silica bricks.

Les Alliages d'Aluminium et de Magnesium, Jean Escard. *Revue Scientifique, Industrielle & Commerciale des Métaux et Alliages,* no. 11, November-December 1917, pp. 1-3. Discussion of various aluminum-magnesium alloys giving, among other things, tables of their melting points and indicating their physical and chemical characteristics and methods of preparation..

L'Emploi de la Pression Plastique du Plomb, M. Lünet. *Le Génie Civil,* tome 72, no. 14, April 6, 1918, pp. 236-238, 11 figs. Description of methods of manufacture of stamped metal articles under lead pressure. An abstract of this article may appear in an early issue of The Journal.

Cooling Rate Affects Steel Casting Design, J. G. Fletcher. *The Foundry*, vol. 46, no. 309, May 1918, pp. 201-204, 2 tables.

The Penetration of Carbon, Howard Ensaw. Discussion of various methods of case-hardening and of the penetration of carbon. Among other things a chart showing penetration of carbon is given, with percentages of carbon as ordinates and degrees of hardness as abscissæ.

The selection of suitable boxes for carburizing is discussed, the writer recommending, as a most suitable material in most cases, steel boiler plate 3/8 or 1/2 in. thick, which can be made with welded joints and will last well.

The sizes of the boxes employed depend to a great extent on the nature of the work being done, but care should be exercised to avoid putting too much in one box, as smaller ones permit the heat to penetrate more quickly, and one test piece is sufficient to give a good indication of what has taken place. If it should be necessary to use larger boxes it is advisable to put in three or four test pieces in different positions to ascertain if the penetration of carbon has been satisfactory in all parts of the box, as it is quite possible that the temperature of the muffle is not the same at all points, and a record shown by one test piece would not then be applicable to all the parts contained in the box. It has been found that the rate of carbon penetration increases with the gas pressure around the articles being carburized, and it is therefore necessary to be careful in sealing up the boxes after packing. When the articles are placed within and each entirely surrounded by compound so that the compound reaches to within 1 in. of the top of the box, the lid, which should be a good fit in the box, is then to be pressed on top of this, and another layer of clay run just below the rim of the box on top of the cover.

A mixture of fireclay and sand will be found very satisfactory for closing up the boxes, and by observing the appearance of the work when taken out we can gage the suitability of the methods employed, for unless the boxes are carefully sealed the work is generally covered with dark scales, while if the sealing is properly done the articles will be of a light gray.

By observing the above recommendations reliable results can be obtained and we can expect uniform results after quenching. (*American Machinist*, vol. 48, no. 18, May 2, 1918, pp. 755-756, 1 fig., 1 chart)

Acid Open Hearth Steel Investigation, T. D. Morgans and F. Rogers. *The Blast Furnace and Steel Plant*, vol. 6, no. 5, May 1918, pp. 216-217.

[illegible] Cold-Worked [illegible] Carbon Steels, F. Cloup. In studying the heat changes brought about in annealing cold worked or heat-treated steel the writer has observed a complete parallelism between these two phenomena. The experiments were carried out in accordance with the differential method of Sir Roberts-Austen and with photographic recording by the double galvanometer of Saladin and LeChatelier.

The following results were obtained:

1 The curve of the rise of temperature in steels which have previously undergone cold-working or heat-treating has in all cases at about 400 deg. cent., a singular point characterized by an evolution of heat.

2 The change of state which takes place at this temperature reaches completion only quite slowly, both in the case of heat-treated steel and in the case of cold-worked steel. Thus, two samples of the same steel, 0.12 per cent carbon, of which one has been tempered from 1000 deg. by immersion in water at 15 deg. and the other cold-worked, then both heated to 640 deg. for a period of 25 min., still show, during the second reheating, the singular point at 400 deg. cent. After a heating for twelve hours at 600 deg. cent. the transformation is completed and a new curve of heating does not show any irregularities.

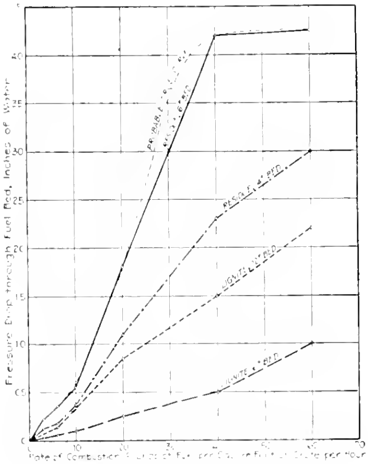

Fig. 1 Draft Required for Lignite

3 This change of state is irreversible. The curves of cooling of both heat-treated and cold-worked steel have the perfectly regular appearance. This transformation must be accompanied by a sudden change of volume. Since the metal is not malleable at 400 deg. cent., it becomes subject to internal stresses which produce a breakdown of equilibrium. If, then, by external work, such as hammering, these internal stresses are still more intensified the most favorable conditions are created to cause rupture of material, which is actually quite frequent when cold-worked steel is heated and subjected to mechanical working at about 400 deg. cent. (*Trempe et Ecrouissage des Aciers au Carbone*, F. Cloup, presented by Henry LeChatelier. *Comptes Rendus hebdomadaires des Séances de l'Académie des Sciences*, tome 166, no. 10 (March 11, 1918), pp. 415-416)

Fuel and Firing

Combustion of North Dakota Lignites, with Suggestions for Design of Furnaces, Henry Kreisinger, Mem.Am. Soc.M.E. An article published by special permission of Dr. H. Van Manning, Director of the United States Bureau of Mines.

In the ordinary furnace with horizontal grate the lignite of North Dakota is very difficult to ignite, and even after combustion has been started troubles are apt to occur.

A special furnace was designed and constructed to satisfy the basic requirement of burning lignite and its carbonized residue. The essential features of this furnace, designed with particular regard to house-heating purposes, are shown in Fig. 3.

In this furnace rapid ignition is obtained by the rear arch, which turns the hot gases and flames back over the fuel bed. Thus, the incoming fresh fuel is heated not only by conduction through the fuel and radiation from the arch, but mainly by convection when coming in contact with the hot gases and flames from the already burning fuel.

Further, to heat lignite having 35 per cent moisture to ignition temperature takes more than twice as much heat as is required to heat bituminous coal containing 10 per cent of moisture. It is therefore difficult, if not impossible, to supply enough heat by radiation from the ordinary front arch to ignite the lignite, and another factor of heat supply must be brought into action—in this case heat transmission of hot gases by convection. The grate is inclined and has wide horizontal air spaces, which can be easily kept open, permitting free flow of air through the grate. Additional air is admitted through the door for removing clinker at the lower end of the grate. As this air passes up between the arch and the fuel it scrubs against the surface of the fuel bed, and a large part of it is consumed in burning or gasifying the solid fuel, thus making it unnecessary to force all the air needed for gasification of the fuel through the fuel bed.

Experiments showed that the scrubbing action of additional air caused a rapid and rather complete oxidation at the surface of the fuel bed, indicated by the bright red heat, which was practically absent on the tests made in an ordinary furnace with horizontal grate. Thus there were two oxidation zones, one next to the grate and one at the surface of the fuel bed, probably with a small reducing zone between them. Because the air which enters through the cleaning door against a low resistance burns or gasifies solid fuel, higher rates of

combustion can be obtained than with ordinary or natural draft.

The air spaces in the grate are horizontal, and the inclination of the grate is such that the fuel is fed from the magazine down the grate by gravity, besides which the rate of feeding can be increased by a slight agitation or rocking of the grate bars. The gravity feeding can be used better with lignite than with most bituminous coals, because the fuel does not cake. The thickness of the fuel bed and, to some extent, the rate of feeding are controlled by the opening of the gate of the fuel magazine.

In the tests made with a draft of 0.1 to 0.15 in. of water, the lignite made a bright, red-hot fire, although the arch never was visible red-hot. When the lignite was broken to pieces not exceeding about two inches, the feeding of the fuel was nearly automatic, though with larger pieces the fuel had to be occasionally moved down by shaking the grate bars and by poking the large pieces through the magazine gate.

Slack, though present in considerable amount, did not seem to cause any particular trouble.

The principles embodied in the design of the furnace for house-heating purposes shown in Fig. 2 can be applied also to boiler furnaces as shown in Fig. 3. There diagram A suggests the design of an inclined step-grate boiler furnace. The fuel can be fed by gravity aided by hand regulation, or it can be pushed out of the magazine mechanically by a pusher plate. There should be as little air as possible entering through the coal magazine or through the plate in front of the coal magazine where the fuel is merely being dried and does not burn.

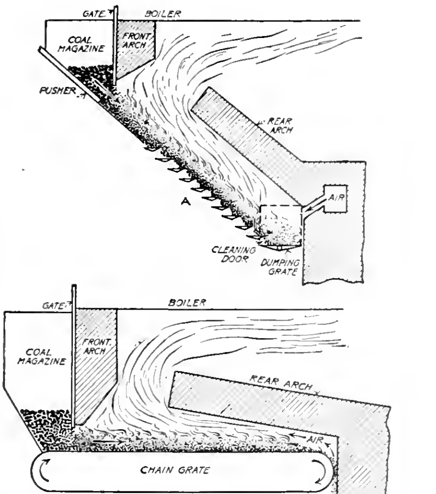

Fig. 2 Experimental House-Heating Furnace for Lignite

The completeness of combustion should be controlled by regulating the air admitted to the lower end of the grate and not by regulating the admission of air through the magazine.

Diagram B shows the application of the same principles to a chain-grate furnace. The diagram shows the grate in horizontal position, and it is believed that better results could be obtained if the top of the grate were inclined about 20 deg. to the horizontal. (*Power*, vol. 47, no. 18, April 30, pp. 608-612, 5 figs. *tpA*)

Entropy Diagram for Gasoline, Jean Rey. The utilization of gasoline in various apparatus as a vapor makes it desirable to have precise knowledge of the physical laws of its vaporization, preferably expressed as an entropy diagram.

The diagram presented here and plotted for ordinary gasoline of density 0.800 to 0.820 (for water = 1.000) has been developed from an investigation extending over many years.

The writer has found that the specific heat can be ex-

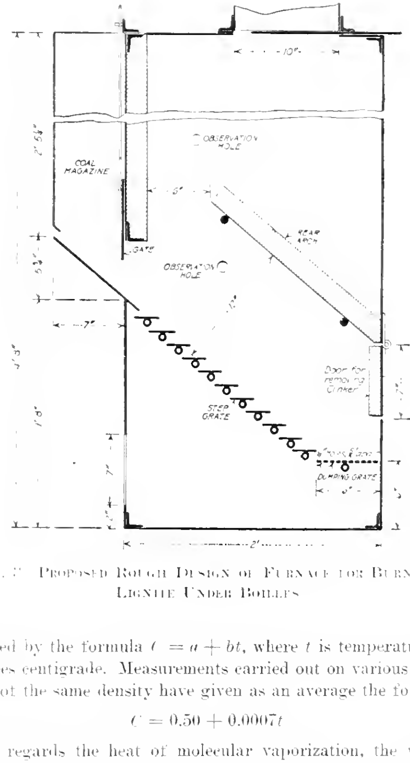

Fig. 3 Proposed Rough Design of Furnace for Burning Lignite Under Boilers

pressed by the formula $C = a + bt$, where t is temperature in degrees centigrade. Measurements carried out on various gasolines of the same density have given as an average the formula

$$C = 0.50 + 0.0007t$$

As regards the heat of molecular vaporization, the writer has determined the value of L/T by comparison with various known organic liquids, namely, chloroform, acetone, sulphur and chloride of carbon.

In plotting the curves, giving L/T as a function of the absolute pressure, one finds that the average curve represents with sufficient approximation the value of the function for ordinary gasoline. This function has the form

$$L/T = a\,T - b$$

where a and b are constants.

For the numerous series of organic liquids, the Bingham formula

$$L/T = 17 + 0.011T_0$$

expresses the heat of molecular vaporization at the temperature T_0, which is the temperature of boiling at atmospheric pressure. It may, therefore, be used as a check for one point on the curve.

On the other hand, the writer has determined the curve of pressures of vapor of ordinary gasoline, which permitted him to plot the values of L/T for gasoline as a function of the

...temperature. Expressing these values as absolute pressures. In this way he obtained the following relation:

$$L/T = 15{,}160/T - 12.42$$

By dividing this expression by μ, the molecular weight of ordinary gasoline, one obtains the heat of vaporization per unit of weight in large calories r, or

$$r/T = 82.4/T - 0.0675$$

or

$$r = 82.4 - 0.0675T$$

The value 184 is a fairly close expression of the molecular weight for the various samples of gasoline tested. It is known that American gasolines are essentially expressed by the formula C_nH_m, where $m = 2n + 2$, while Russian gasolines correspond to formula C_nH_{2n}. Ordinary gasoline, which is nothing but a mixture, is expressed with sufficient exactness by $C\,H$.

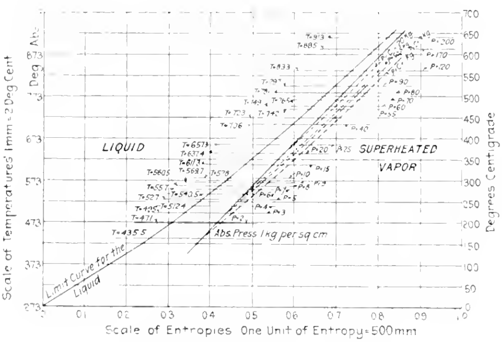

FIG. 4 ENTROPY DIAGRAM FOR GASOLINE

With these magnitudes established, one finds that the entropy of the liquid is given by the expression

$$S_{liq} = \int_0^T \frac{dq}{T} = \int_0^T \left[0.50dT + 0.0007(T - 273)\frac{dT}{T}\right]$$

$$= 0.3089 l\left(\frac{T}{273}\right) + 0.0007(T - 273)$$

It is only necessary to add to this expression r/T in order to obtain the entropy of the saturated vapor, which is

$$S_{vap} = 0.3089 L_n\left(\frac{T}{273}\right) + 0.0007T + \frac{82.4}{T} - 0.2586$$

It is by means of these formulæ that the diagram, Fig. 4, has been plotted. In order to verify the heat of vaporization, the writer used a special tubular boiler so designed as to make it possible to obtain pressure rapidly. After vaporization, gasoline condenses in a nest of pipes cooled by water from the outside. With this arrangement all that is necessary is to measure the amounts and the inlet and outlet temperatures of water and gasoline. The same apparatus was used for measuring the vapor pressures.

Certain precautions were necessary due to the fact that gasoline cannot be kept above a certain temperature without undergoing polymerization.

From the curve of vapor pressures one may deduce the following expression where T is the absolute temperature of boiling of gasoline expressed as a function of T_w, which is the absolute temperature of boiling of water at the same pressure:

$$T = 1.167T_w - 0.641(T_w - 273)$$

The various points in the entropy diagram reproduced here have been checked up to a pressure of 40 kg. (569 lb. per sq. in.). These checks have shown possible errors of from 1 to 2 per cent. The inspection of the diagram shows at once—

1 That the saturated vapor of ordinary gasoline is superheated through fall of pressure, and
2 That the heat of the liquid is always considerably higher than the heat of vaporization.

From these two properties, which are directly opposite to those of water vapor, it follows that when saturated vapor of gasoline is allowed to expand it is simultaneously superheated and produces mechanical work. If liquid gasoline under pressure is allowed to have part of its pressure removed it is partially vaporized, and if this lower pressure is maintained for a sufficiently long time, its vapor is superheated.

These properties are probably common to all the principal hydrocarbons. (*Comptes Rendus Hebdomadaires des Séances de L'Académie des Sciences*, vol. 166, no. 9, March 4, 1918, pp. 387-390, 1 fig., *teA*)

CONSERVING FUEL BY COAL BRIQUETING, F. Denk. *The Coal Industry*, vol. 1, no. 4, April 1918, pp. 129-131.

ECONOMY IN THE USE OF FUEL IN POWER STATIONS, Charles H. Parker. *Journal of the Boston Society of Civil Engineers*, vol. 5, no. 4, April 1918, pp. 163-185, 10 figs. An extensive paper devoted to the various features of power-plant operation having a bearing on fuel economy.

COMBUSTION OF COAL AND DESIGN OF FURNACES. *Power*, vol. 47, no. 17, April 23, 1918, pp. 596-600.

CARBOCOAL, Charles T. Malcolmson. Description of a series of experiments which are said to have resulted in the development of a process for the manufacture of a smokeless fuel from volatile coals and for the recovery and refinement of the coal-tar products derived therefrom. The process described is the invention of Charles H. Smith.

The essential features of this process are two distillations carried on at different temperatures; first of the raw coal and second of the raw briquets. The raw coal, after being crushed, is distilled at a relatively low temperature, 850 to 900 deg. fahr., and the volatile contents are thereby reduced to the desired point. The result of this first distillation is a large yield of gas and tar, and a product rich in carbon, termed semi-carbocoal. The semi-carbocoal is next mixed with a certain proportion of pitch obtained from the tar produced in the process, and this mixture is briquetted. The briquets are then subjected to an additional distillation at a higher temperature, approximately 1800 deg. fahr., resulting in the production of carbocoal, the recovery of additional tar and gas, and a substantial yield of ammonium sulphate.

The characteristic feature of the primary distillation is that it is continuous and that the coal is constantly agitated and mixed during the entire operation. This is accomplished by a twin set of paddles, which also advance the charge through the retort. By this means all portions of the charge are uniformly distilled, and by controlling the speed at which the charge moves through the retort, the distillation may be arrested at any desired stage. As only a partial carbonization is permitted in the primary distillation, the hard metallic cells characteristic of coke are avoided. The period of distillation is one to two hours, and the continuous retort has a carbonizing capacity of one ton of coal per hour.

In the subsequent distillation of the briquets all evidence of the pitch as a separate ingredient disappears. There is a

marked shrinkage in the volume of the briquet, with a corresponding increase in density, but no distortion of its shape. This distillation requires four to five hours, and is performed in an inclined, self-charging and self-discharging bench.

The carbocoal represents more than 72 per cent of the weight of the raw coal, the exact percentage depending upon the volatile content of the latter.

Carbocoal is dense, uniform in size and quality, grayish-black in color and is manufactured in briquet form in any size from 1 oz. to 5 oz. It is stated that it has been tested by the Long Island R. R., by the Pennsylvania R. R. at Altoona, the Carolina, Clinchfield & Ohio R. R. and by the U. S. Navy, and that it requires no greater draft than bituminous coal.

The analysis of carbocoal indicates from 1 to 3 per cent of moisture, from 0.75 to 3.50 per cent volatile matter, 82 to 90 per cent of fixed carbon and 7 to 12 per cent ash.

The article also describes in brief the recovery of tar and other by-products. (*Bulletin of the American Institute of Mining Engineers,* no. 137, May 1918, pp. 971-977, 3 tables)

The Burning of Pitch and Creosote Mixtures. Furnace and burner makers had not considered the burning of pitch mixtures until the subject was taken up by the Ministry of Munitions. The apparatus used was crude and of an elementary design. The use of creosote oil as fuel by the British Navy is likewise of comparatively recent origin.

Now, in order to increase the available supplies of creosote for naval purposes, steps were recently taken in Great Britain to limit its use in other directions by a system of licenses.

Admiralty supplies were increased to a point at which it appeared that further supplies could be drawn only from oil now consumed in the land furnaces. This is why the question of burning pitch, or rather pitch and creosote mixtures, was taken up in earnest, the successful use of such mixtures becoming a matter of great national importance.

The coöperation of furnace makers was first obtained, primary attention being given to those making use of oil for steam raising. Extensive trials were carried out with pitch and creosote mixtures, using modern pressure-jet systems. During these tests two companies successfully handled mixtures containing 60 per cent and 75 per cent of pitch and obtained boiler efficiencies of over 80 per cent working under natural-draft conditions. The fuel in the supply tank was kept at a temperature of about 130 deg. fahr. and was raised to 290 deg. fahr. at the burners, the fuel pressure being maintained at about 75 lb. per sq. in. Another company who used the White system for steam raising obtained a boiler efficiency of 82 per cent under forced draft from a mixture consisting of 70 per cent creosote and 30 per cent pitch, and are now using commercially in all their furnaces a mixture of 66.6 per cent creosote and 33.3 per cent pitch with satisfactory results.

Manufacturers of reheating, smelting and other furnaces were likewise induced to carry out experiments and have obtained promising results.

The chief difficulties in burning pitch and creosote mixtures lie in the handling and transport of the mixture and the presence of certain bodies in the pitch which necessitate increased attention to the burners. As regards transhipment of fuel, little difficulty has been experienced when the consumer has a railway siding available to take delivery and the tank wagons are equipped with steam coils.

The trouble experienced in burning certain mixtures is a very real one, and is due to the presence of free carbon, resinous matters or other foreign bodies contained in the pitch blocking up the burners and strainers. In practice it has been found that the pitch and any other liquid fuel which is rich in free carbon usually present difficulties in burning. It is recommended that consumers of pitch fuels should have their systems fitted with alternative strainers, so that when one strainer becomes choked up another may be operated while the first is being cleaned. Internal-Combustion Engineering (See also Fuel and Firing)

Heavy-Fuel Engine with Detonating Igniter. Description of a heavy-fuel igniter working on the principle of detonation. The description is very incomplete because of legal formalities in connection with patent rights.

It is stated generally that the suction in the engine cylinder as the piston descends on the induction stroke is transmitted through a narrow passage in the foot of the detonator to its interior. Arrived at this point the suction opens a non-return valve inside the detonator and thence exerts its influence in the pipe connecting the detonator with the supplementary carburetor.

As regards the carburetion, it is stated that kerosene is merely broken up at the jet, the effective aperture of which is rendered rather smaller than usual by the insertion of a larger jet needle.

In addition to this there is a small auxiliary carburetor mounted above the cylinders and provided with two float chambers, one for gasoline and the other for a heavy fuel. Leading from this supplementary carburetor is a pipe with branches passing to a small receptacle known as a detonator screwed into each spark-plug hole.

On every induction stroke of the piston fuel is drawn both from the main carburetor into the combustion chamber and cylinder of the engine and from the supplementary carburetor along the appropriate branch pipe into the interior of the detonator mounted in the spark-plug hole of the same cylinder of the engine.

At the end of the induction stroke the suction ceases and the non-return valve in the top of the detonator closes under the influence of a light spring, so that the mixture in the detonator cannot escape back to the supplementary carburetor on the compression stroke of the engine piston. As this stroke proceeds, the main charge is compressed in the combustion chamber and a small proportion is forced up through the narrow opening in the foot of the detonator into the body of the detonator itself.

In the upper part of the detonator, however, the mixture from the supplementary carburetor is stated to lie compressed practically as a stratum on the top of that portion of the main charge which has been forced up into the lower part of the detonator. Into the side of the detonator is inserted a spark plug of ordinary design, the spark occuring on the completion of the compression stroke. It is said that the spark fires first of all the stratum of mixture drawn from the supplementary carburetor which ignites the heavier fuel in the detonator, and

tion, the flame rushes downward through the foot of the detonator into the engine combustion chamber. The heat intensity and area of the flame from the burning of the detonator charge are stated to be such that the temperature of the main charge instantly rises to a very high point, which makes its combustion practically perfect.

It is stated that the fuel drawn from the supplementary carburetor (gasoline) is only two per cent of the whole. (*The Autocar*, vol. 40, no. 1172, pp. 338-340, 1 fig., *d*)

Machine Tools

Air-Turbine-Driven Grinding Wheel, W. J. Nene. Description of a machine designed especially for grinding welds. One of the greatest difficulties associated with electric welding of cast iron in the small shop is a tendency to leave the weld so hard as to be practically unworkable except by an abrasive wheel. The operator therefore has to have some quick and efficient means of working down these hard spots.

The machine described is simply an air turbine of special design, carrying an abrasive wheel on the end of its rotor shaft. The writer vouches for the efficiency of the machine and states that the turbine at 90 to 100 lb. pressure furnishes ample power to drive a 3-in. wheel at 3500 r.p.m., which is approximately correct for a wheel of this size.

The parts are made of mild-steel forgings, except the ring *D* and the bearings, which are of hard brass, and the ball races, which are of tool steel hardened and ground.

The compressed air enters the annular chamber marked "air space," Fig. 5; thence it flows through the air ports, that is, the fifty-seven 3/64-in. drilled holes, and impinges at high velocity on the air pockets in the rotor *A*, imparting to it the first rotary impulse. At this point the air divides, part flowing through the 1/16-in. holes in the rotor and thence toward the center, where it exhausts through the six ⅞-in. holes, while the larger portion of the air flows through the 1/64-in. opening between *A* and *D*, where it comes in contact with the vanes

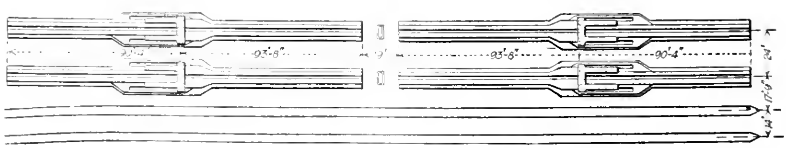

Fig. 6 Shop Layout for Four 90-Ft. Planing Machines

or wings which form part of the rotor and are set at an angle of 45 deg. with the axis of the rotor.

As the combined area of the fifty-seven air ports is approximately 0.098 sq. in., a ⅜-in. air hose would furnish an ample supply of air; but the usual standard connection for small hose is ½ in., and for this reason the air intake of the machine is made of this size.

It is stated that when this turbine runs at full speed it seems to use very little air. (*American Machinist*, vol. 48, no. 16, April 18, 1918, p. 658, 1 fig., *d*)

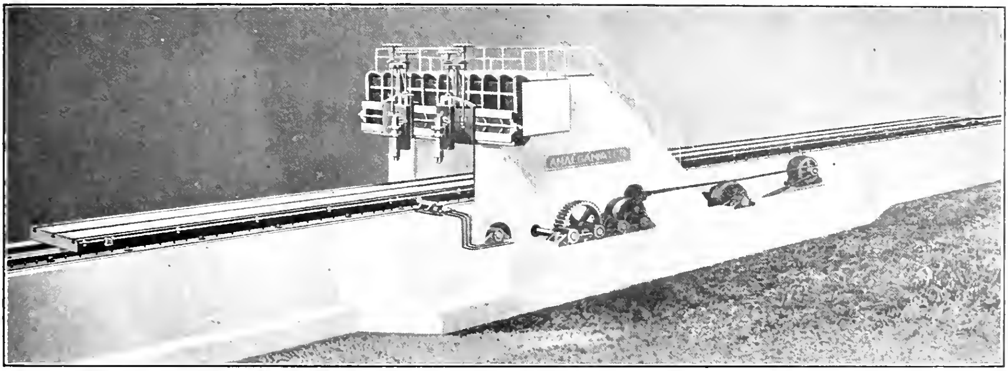

FIG. 7 REINFORCED-CONCRETE PLANING MACHINE WITH 80-FT. BED FOR WORK ON GUN-BORING MACHINES

CONCRETE METAL-PLANING MACHINES, Ethan Viall, Mem. Am.Soc.M.E. Description of a machine tool which represents a radical departure from common practice and may offer important possibilities for the future.

The machines here described were built by the Amalgamated Machinery Corporation, Chicago, primarily for the purpose of planing the beds of large gun-boring machines for the Government. The striking features of their construction and execution are first the use of reinforced concrete for the bed of the machine and next the speed with which the machine was built.

The original construction plan for these machines comprises a battery of four planers, each with a bed 184 ft. long, 17 ft. at its widest place and 18 ft. from the bottom of the bed to the top of the housing. There are approximately 212,000 lb. of iron and steel castings in each machine and about 13,500 cu. ft. of concrete reinforced with 34,000 lb. of steel bars. See Fig. 6.

A view of one of these machines is given in Fig. 7 and details in Figs. 8, 9 and 10.

The bed was designed like a huge concrete girder intended to support a load, which accounts for the high percentage of steel reinforcement. This was done to avoid any possibility of the bed settling at any point and destroying the alignment of the ways.

The bed ways are made with one flat guide and one V-guide. The ways are made in sections 12 ft. long, 4 ft. 10 in. wide and 13 in. through the thickest point. The V is cut with a 50-deg. slope angle and is 10 in. wide at the top of the flare. The flat guide is 10 in. wide at the top. After the table sections have been fastened together concrete is poured into the box-like sections, making the table one long, solid monolith of concrete and iron.

The method of feeding the cutting tools is quite unusual, no automatic means of feeding being supplied. Each cutter head is controlled independently in both horizontal and vertical

Measurements

INNOVATIONS WITH RESPECT TO MICROMANOMETERS, M. Berlowitz. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 969-973, Dec 8, 1917.) Interest in air measurements has been aroused during recent years to an unusual degree, particularly as regards ventilators and compressors; in consequence, a large number of manometric improvements have been forthcoming. The author here presents a summary of the various innovations which have been proposed. The differential manometer of G. Recknagel, which itself was a development of Péclet's earlier apparatus, and which for a number of years was the only instrument for measuring very low pressures, is first described in detail. Owing to serious inconvenience involved in the use of this instrument, a new construction was proposed by Krell, to which he gave the name micromanometer. A full de-

... apparatus is ... the paper. Further ... experiments by Berlowitz and Schultz are then discussed, the ... details being illustrated by eight diagrams. The paper concludes with a mathematical discussion of the mechanism ... manometric measurement, accompanied by two tables of results. APPARATUS AND MACHINES FOR TESTING OF AEROPLANE MATERIALS. *Canadian Machinery*, vol. 19, no. 18, pp. 465-468, 8 figs.

ERICHSEN TESTS ON ALUMINUM SHEETS, Robt. J. Anderson. Results of tests made with the Erichsen ductility testing apparatus on annealed 18-gage aluminum sheets. The Erichsen apparatus consists essentially of a die and holder for holding the sample to be tested and an internal tool actuated by a hand wheel which moves gradually forward until the sample is ruptured. The progress of the internal tool and the ultimate fracture are observed in a mirror and the depth of indentation is read directly from a micrometer graduated screw.

One of the features of this test is the evidence of approximate grain size of the metal tested, which fractured domes of the test pieces indicate. This makes this test valuable as a guide to drawing operations on an annealed metal, since underannealed metal will rupture by deep draws owing to its hardness and lack of ductility, while overannealed metal will also rupture because of the weakened condition of the metal resulting from large grain size.

The Erichsen test indicates how a given metal may be expected to behave in the draw press; in fact, the apparatus itself is nothing but a miniature draw press. The ductility control of metal going into draw-press work may be expected to reduce the percentage of scrap largely and to provide a rational basis of control for the annealing operations.

In this instance are described tests on 18-gage aluminum sheets, preliminary tests being made on a lot which had worked badly in the draw press. Then a number of tests were made upon 18-gage cold-rolled aluminum sheets reduced in the cold from a 0.25-in. slab to 18 gage. The metal employed

TABLE 1 EFFECT OF ANNEALING 18-GAGE ALUMINUM SHEETS: TEMPERATURE VARIABLE, AND TIME CONSTANT AT TWO HOURS

Sample	Temperature in deg. cent.	Thickness in millimeters	Indentation in millimeters	Scleroscope hardness	Appearance of domes
1	As rolled	1.08	6.83	14.0	
2	100	1.08	6.96	13.5	
3	200	1.09	8.39	10.0	
4	300	1.07	10.17	4.5	Smooth
5	400	1.07	10.10	4.5	Medium
6	500	1.09	9.73	4.0	Coarse

Note—(a) Time constant at 120 min.; (b) Values given represent the mean of two closely agreeing determinations.

TABLE 2 EFFECT OF ANNEALING 18-GAGE ALUMINUM SHEETS, TIME VARIABLE AND TEMPERATURE CONSTANT AT 200 DEG. CENT.

Sample	Annealed, minutes	Thickness in millimeters	Indentation in millimeters	Scleroscope hardness	Appearance of domes
7	5	1.07	6.89	13.8	
8	30	1.07	7.97	11.8	
9	60	1.08	8.40	9.5	
10	90	1.09	8.84	8.0	
11	150	1.09	8.87	8.0	

Note—(a) Temperature constant at 200 deg. cent.; (b) Values given represent the mean of two closely agreeing determinations.

was American metal of high purity containing over 99 per cent aluminum with impurities normal. The annealings were made in a laboratory electric furnace of the resistance type under pyrometric control and the temperatures are accurate within 10 deg. cent. The results are given in tables, of which two are here reproduced. Table 1 shows that the metal under discussion attained maximum softness by annealing at 300 deg. cent. for two hours. The effects of annealing at the constant temperature of 200 deg. cent. for various times is given in Table 2 and the data therein show that 200 deg. cent. is too low a temperature to employ for annealing 18-gage cold-worked sheets. Other tables show that complete softening below 5 Shore scleroscope number was obtained by annealing for 1 hr. and 20 min. at 300 deg. cent. Another table shows that complete annealing may be effected by an exposure of 5 min. at 400 deg. cent., which indicates that long-time exposures are unnecessary and may often lead to an increase in waste of material. Figs. 11 and 12 graphically reproduce the data in Tables 1 and 2, while Fig. 13 shows what happens in the case of annealing at 400 deg. cent.

The original article also refers to two other figures, which, however, do not appear in the article. (*The Iron Age*, vol. 101, no. 15, April 11, 1918, pp. 950-951, 4 figs. *ep*)

Mechanics

THE VALUE OF "g" IN ENGINEERING AND PHYSICAL WORK, Sanford A. Moss. The effects of variations in gravity, the cases where the effects are negligible, and the cases where they must be taken into account, are discussed from the point of view of the engineer and physicist.

The correction data, previously given completely only in inaccessible treatises on geodesy, are given in a form more convenient for actual use than ever given before.

The author collaborated with the Coast and Geodetic Survey officials, and with Prof. E. V. Huntington, so that the data may be regarded as authoritative.

The standard value of g is 980.665 cm. per sec.² or 32.1740 ft. per sec.² This has been arbitrarily selected by international agreement. It is nearly the average value at sea level, 45 deg. N. latitude, but is to be arbitrarily maintained regardless as to whether it is the exact average value, and regardless of

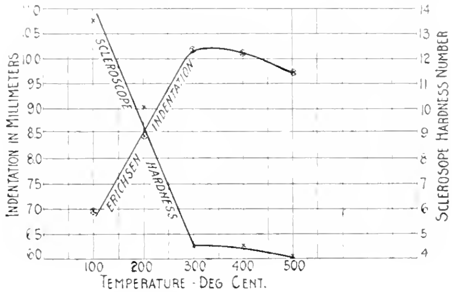

FIG. 11 TEMPERATURE-INDENTATION AND TEMPERATURE-SCLEROSCOPE-HARDNESS CURVES FOR ANNEALINGS ON 18-GAGE ALUMINUM SHEETS. TIME CONSTANT AT 120 MIN.

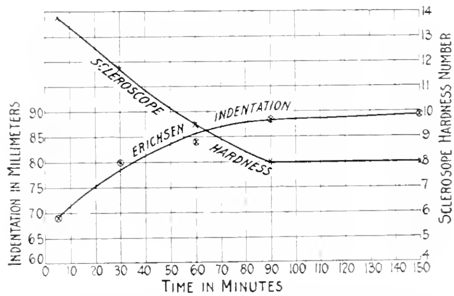

FIG. 12 TIME-INDENTATION AND TIME-SCLEROSCOPE-HARDNESS CURVES FOR ANNEALINGS ON 18-GAGE ALUMINUM SHEETS. TEMPERATURE CONSTANT AT 200 DEG. CENT.

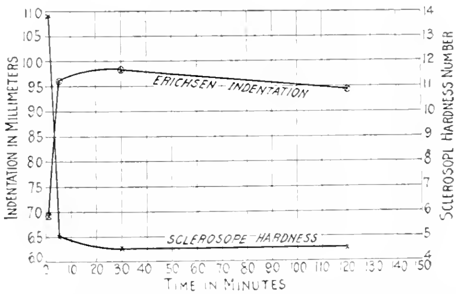

FIG. 13 TIME-INDENTATION AND TIME-SCLEROSCOPE-HARDNESS CURVES FOR ANNEALINGS ON 18-GAGE ALUMINUM SHEETS. TEMPERATURE CONSTANT AT 400 DEG. CENT.

changes in the average observed value due to addition of new data.

In all cases where a force of a pound is used it is to be understood as being the "standard pound force," which is a force giving the "standard weight" of one pound an acceleration of the standard value, g_s.

Whenever forces are measured by instruments which depend

ope. The attraction of gravity the readings must be reduced to standard pounds by use of the correction factors given. Examples are: platform scales used with Prony brakes or similar brakes, dead-weight gages, mercury or water U-tubes, and testing machines. The correction for latitude has a maximum value of about fourteen hundredths of one per cent (in the southernmost part of the United States.) The correction for elevation is about one one-hundredth of one per cent per 1000 ft. elevation. There is a further correction for "anomaly," which is about one one-hundredth of one per cent on a few mountains and less than half of this value everywhere else, so that it is negligible for engineering work.

The following table gives the principal correction factor to within 1/100 of one per cent, which is accurate enough for engineering purposes.

We multiply the measurements of a force in a weight scales by the correction factor in the body of the table and add it to the reading.

North Latitude, deg.	Elevation in feet, ft.							
	0	2000	4000	6000	8000	10000	12000	14000
25	0017	0019	− 0021	− 0023	0025	0027	− 0029	− 0031
30	− 0014	− 0016	− 0018	0019	0021	− 0023	− 0025	− 0027
35	0010	− 0011	− 0013	− 0015	− 0017	0019	− 0021	− 0023
40	− 0005	− 0007	− 0009	0011	0013	0015	− 0017	− 0019
45	0001	− 0002	0004	− 0006	− 0008	− 0010	− 0012	− 0014
50	− 0004	+ 0002	0000	− 0002	− 0004	0006	− 0007	− 0010

More accurate correction data are given, which are needed, however, only for refined physical work.

Taking W, as the weight of a body at any point found by comparing it with the "standard pound weight" by means of a weight scales, F as force measured in "standard pounds" as already defined, and a as acceleration in ft. sec.², the well-known fundamental equation then becomes

$$F = W\,a/g$$

In all formulæ in which g occurs in connection with the standard units mentioned, the value is understood as being g_s, regardless of place.

The now usually accepted definition makes the horsepower exactly equal to 746 watts. This gives 550.22 "standard foot-pounds." (*General Electric Review*, vol. 21, no. 5, May 1918, gt)

DESIGN OF SPRINGS FOR OSCILLATING MASSES, G. Lindner. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 907-912, Nov. 10, 1917.) The author cities various applications in which oscillating masses are fitted with springs to relieve a crank drive of acceleration forces or, in general, to permit a certain latitude of motion in one part while relieving others of shock. A number of formulæ are given to facilitate the choice of a suitable type and size of spring for any particular application. One of the primary functions of springs is to relieve the driving members (e.g., connecting rod, eccentric and crankshaft bearings, etc.) of "free forces" due to reversal of oscillating masses, which free forces cannot be balanced within the machine itself. The spring should be capable of continuing the oscillating motion; in other words, the drive has only to overcome the air resistance and friction of the moving parts once the oscillation is started. In order to secure the same frequency, the force exerted by the spring at maximum deflection must equal the centrifugal force of the oscillating mass at its dead point. The centrifugal force exerted at the distance r cm. from the center by G kg. at n revolutions per minute is: $P = (Gr/100)(n/30)^2$. The spring is designed so that it is deflected r cm. by the force P, and is not then overstressed. The present comparison between various types of springs is based on the following assumptions: Spring steel with $E = 2{,}200{,}000$ kg./cm.²; bending stress at deflection r cm. = 3000 kg./cm.² unhardened and 4000 to 5000 kg./cm.² hardened; half these values for machine steel. In a numerical example for each case $G = 50$ kg.; $r = 2$ cm.; $n = 300$ r.p.m.: then the centrifugal force and spring force $P = 100$ kg. The cases considered are: Parallel plate spring with one end fixed and with both ends fixed; triangular plate springs and the practical form of the latter, the trapezium plate; rectangular and round rod springs (including the case of a bundle of rods and that of rods held at both ends); cubic paraboloid (round rod to uniform resistance); and tapered round-rod springs. In each case formulæ are given for the relation between length and cross-section of springs, for the volume and for the work done in bending the springs, etc. The liability to buckling is discussed, and it is shown how to complete practical designs after obtaining the dimensions theoretically desirable. Sections of uniform resistance or approximations thereto are most economical of material. Rod springs of standard profile may be conveniently applied to a variety of load conditions and they are flexible in all directions. Parallel round-rod springs require four times as much material as triangular plate springs and 4/3 times as much material as parallel plate springs and rectangular rods owing to the fact that maximum stress exists only in the clamped section and along the outer fiber thereof. If the form of the rod be a cubic paraboloid, the material required is only 1/3 that of a cylindrical round rod and 4/3 that of a triangular plate spring. The section in which maximum stress occurs in a tapered round rod depends on the degree of taper. Up to the critical ratio of taper, $D/d = 1.5$, the stress at the clamp determines the design; with more pronounced taper, the danger section moves toward the point of the spring. The relative economy in material of various patterns of spring is shown by the following formulæ for their volume:

	Volume		Volume
Parallel plate spring.........	2.2 Pr	Plain taper round rod:	
Triangular plate spring......	0.73 Pr	With D/d = 1.0	2.935 Pr
Trapezium plate spring:		D/d = 1.25..........	1.91 Pr
limits	0.73 to 2.2 Pr	D/d = 1.5	1.377 Pr
Trapezium plate spring:		D/d = 1.84 (max. economy).	1.18 Pr
b/B = 1/5.....	0.97 Pr	D/d = 2.0	1.20 Pr
Rectangular-rod spring	2.2 Pr	D/d = 2.5	1.45 Pr
Parallel round-rod spring.	2.935 Pr	D/d = 3.0	1.88 Pr
Cubic paraboloid..	0.978 Pr		

The thickness of a plate spring is limited by the deflection, and its breadth by the force and frequency. In a bundle of spring rods either the number or the length may be chosen freely. Some of the formulæ in the original may be simplified for approximate calculations. (*Science Abstracts,* Section B—Electrical Engineering, vol. 21, part 2, no. 242, pp. 64-65)

Substitutional Tiring for Passenger Automobiles, A. Heller. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 879-881, Oct. 27, 1917.) During the last year various substitutes have been devised for pneumatic tires on passenger automobiles; these substitutes being practicable under war conditions, though not entirely satisfactory. The decree of December 18, 1916, relaxed the law restricting the speed of vehicles with other than rubber or similar elastic tires to 25 km. per hr. The decree of April 24, 1917, recognized six patterns of substitutional tiring as permissible until further notice.

Substitutes for pneumatic tires fall into two classes: (1) Those with a rigid rim of metal or wood capable of moving only in the direction of the spokes; and (2) those in which "spoke springing" is supplemented by a species of "rim springing," i.e., a flexible rim in addition to springs between the two rims. Typical examples of both types of tires are given in the original.

The Arop wheel is simple and effective. A single or a double row of spiral springs wound from square steel is carried by doweled spring plates or mountings between an inner and outer rim; but this arrangement is not suitable for high-speed vehicles because the springs are not secure against displacement by lateral forces when running round curves or over obstacles. This risk is eliminated in the Moll wheel by placing each spring between two end caps which are spherical on their outside and provided with tubular extensions down the inside of the spring. One of these extensions slides within the other, forming a telescopic combination which prevents lateral displacement of the spring, while the spherical ends permit lateral displacement of the rim.

The special advantage of the Fruth wheel, built by the Maschinenfabrik Augsburg-Nürnberg, is that the springs are protected against bending or displacement by the peripheral force accelerating or retarding the vehicle. Oval springs are placed between the inner and outer rim on their sides, so that the wheel pressure comes in the plane of the winding. Successive springs are overlapped (going circumferentially round the wheel), and cross-bolts pass through the overlapping loops. The springs lie in two U-troughs which fit one within the other and relieve the springs from all transverse forces. The outer rim and the complete spring system can be mounted as one piece on the inner rim as substitute for a rubber tire. Replacement of broken springs is not easy.

The Sievert wheel uses a composite wooden rim (part of its timber being cross-cut) with steel side rings, between which and the sides of the inner rim are rings of rubber or other elastic material. The whole load is transmitted through the rubber side rings; these have a long life, since they are protected by the side plates. Wear comes on the wooden road rim.

The Siemens and Halske wheel uses spiral springs mounted radially between cups attached to the inner and outer rims. In addition, the outer rim consists of continuously wound strip steel secured by cross-clamps at intervals and protected by leather or similar material which is riveted on and renewed as required. The springs are inadequately protected against dirt and against transverse forces, but the elastic rim improves the smooth running of the wheel and reduces the risk of side slip. The Flohr wheel is of similar construction, but the outer rim is built up on the same principle as the link belt. The link pins serve as supports for the spring cups on the outer rim, but they are not protected against dirt and water. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, part 3, no. 243, March 31, 1918.)

Saving Coal by Mixing. Description of experiments on the Lehigh Valley R. R., where it is said the consumption of coal has been reduced by nearly a third by using the new plan.

This new plan provides for the crushing of bituminous coal and its mixture with anthracite silt, using two parts of the soft coal to one of the silt. Silt or slush is a dust which has passed through a mesh with openings less than 3/32 in. in diameter. It has always been considered as a useless waste, and all over the anthracite fields there are lying great banks of such silt.

A mixing plant has been erected at Hazleton, Pa., where the soft coal is crushed and mixed mechanically with the silt in the proper proportion. Additional mixing plants are now in process of erection. The process is important in view of the fact that it is estimated that millions of tons of silt are available. The Waste-Heat Boiler for Malleable Furnaces, Arthur D. Pratt. Paper presented at the Boston convention of the American Foundrymen's Association. The theory of the waste-heat boiler is discussed and its advantages in the application in malleable-cast-iron foundries brought out.

The writer points out the changes in waste-heat-boiler design which have been developed in the last five years by a better comprehension of the theory of operation of this unit. The fact is especially brought out that in the modern design of waste-heat boilers high gas velocities are employed to secure the necessary rates of heat transfer. This necessitated the use of much smaller gas-passage areas, which, in turn, resulted in a greatly increased draft resistance through the boiler, with such changes in design as would naturally be brought about by this. Feed Arrangements for Turbines Having a Steam Velocity Greater Than That of Sound, G. Zerkowitz. (*Zeits. Vereines Deutsch. Ing.* 64, pp. 869-873, Oct. 27, and pp. 889-892, Nov. 3, 1917.) The present papers contain a critical examination of the conditions prevailing in the inlets of steam turbines working at velocities exceeding that of sound. The form of the radial deflection of the inlet current of steam was determined for the cases of an ordinary parallel-walled pipe and a DeLaval nozzle. The experimental procedure adopted is described in detail. It was found that, at the diagonal cut, there was at one time the behavior of an enlargement, and at another time of a constriction. The case of free expansion was studied and a relation obtained for the average deflection which shows a noteworthy agreement with radial diagrams already in existence. It appears that the average deflection thereby arising is smaller than that given for a simple expansion from a point—a circumstance which is of value for the case of slot expansion. Finally the procedure during expansion from a point was examined and graphed. From the results the deviations which occur with ordinary feed apparatus were established, and a method of adjustment thereby indicated for obtaining a uniform deflection of all stream lines when the steam velocities are greater than that of sound. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, part 3, no. 243, March 31, 1918, pp. 81-82.)

Temperature Control for Superheated Steam, H. Huebner. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 885-888, Nov. 3, and pp. 921-924, Nov. 17, 1917.) It is impossible to obtain precisely the desired superheat unless some means of control is provided. The dryness factor of steam leaving the boiler depends on the water circulation, which latter, even in the same boiler, varies with load and other factors. The heat-transmission factor is commonly taken to vary only with the velocity of the gases, but the temperature difference between gases and steam has undoubtedly an important effect. Even were a completely reliable formula available, it would still be impossible to determine the actual value of all the variables and to realize exactly the anticipated superheat. The steam temperature varies with the length of flame; and a higher temperature is reached with mechanical stoking and ash removal than when doors are opened frequently under manual control. Temperature and quantity of flue gases and dryness of steam vary considerably with the load on the boiler.

The effect of the superheat may be controlled by dampers, by water cooling, or by varying the moisture content of the "saturated" steam. Control by dampers is used most frequently, but this is not the best system. It is true that damper control strikes right at the root of the matter by cutting off the flue gases more or less completely from the superheater, but the damper doors are heavy to move and require massive supports, also they depreciate rapidly in service. The author illustrates several arrangements of swinging dampers and discusses their merits and defects. In one good form the dampers are not exposed to the hottest gases. It is generally easier to accommodate the dampers in water-tube boilers with vertical or steeply inclined tubes. Sliding dampers of refractory material are more durable and reliable than pivoted metal dampers in boilers with very high superheat. Bypass openings with refractory shutters may be used to allow more or less of the flue gases to escape without passing through the superheater; the bypass is adjusted to give correct superheat on normal load. On the other hand, the use of a bypass involves some sacrifice of boiler efficiency even though the hotter emerging flue gases be passed through an economizer. Any arrangement of dampers which involves providing a second gas path below the superheater, necessitates higher and more costly boiler setting and boiler house.

The Babcock and Wilcox temperature control uses the boiler water to cool the superheated steam to the desired temperature. This system is conveniently efficient and gives accurate control over a wide range without wasting space. A 3-way valve is used to determine the proportion of the superheated steam that is passed through the cooling pipes in the boiler. The steam temperature in the superheater itself is unaffected by this system of control and should therefore not exceed 180 deg. to 500 deg. cent., or there will be serious risk of the superheater tubes being overheated and softened. Subdivision of the superheater and taking part of the steam out to a cooling pipe in the boiler before returning it to the superheater, does protect the latter, but also introduces additional pipes, fittings, and pressure loss.

In the Kose regulator all the superheated steam is passed through a bundle of cooling tubes which is automatically submerged to a greater or less extent in the boiler water so as to maintain any desired steam temperature. If steam be passed through an independent cooling drum (fed with hot feed-water and delivering any steam raised to the main boiler), the

temperature of superheat is controlled effectively and the cooler and boiler are both more accessible for cleaning, etc. In the Wedertz regulator, water from the boiler is passed through a cooling tube mounted concentrically in a late stage of the superheater. Steam raised in the cooling tube is admitted to the steam main. The superheater itself is protected by this device, but fitting the cooling tubes offers mechanical difficulties. The Steinmuller regulator bypasses part of the steam rising through the front header and uses it to blow more or less water into the steam going to the superheater. From 80 to 100 deg. cent. control is obtained and the superheater does not exceed the temperature of the steam delivered. In the Germaniawerft regulator, water is sprayed into the superheater tubes from a concentric water pipe which has a number of fine holes on a spiral at the base of a helical strip mounted between the two tubes and serving to insure thorough evaporation.

In order to prevent formation of scale deposits in the superheater, Walther et Cie. use for cooling the overheated steam only pure condensate obtained by taking part of the boiler steam over a miniature surface condenser through which feedwater passes. In any case it is important that no unvaporized water particles be carried forward by the superheated steam. Temperature reduction by mixing saturated with superheated steam is practicable only where the superheat is moderate and the desired temperature decrease is small. A 3-way hand valve or an automatic valve may be employed. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, part 3, no. 243, March 31, 1918, pp. 86-87.)

STEAM TURBINE OF LARGE SPECIFIC OUTPUT AND THE EMPLOYMENT OF DISKS WITH SHRUNK-ON BOSSES. In order to take care of the great volume of steam after it has expanded and at the same time to avoid excessive leakage losses, the last disk of a large turbine must be of great diameter and have long blades. The body of the disk is then subject to great peripheral strains and speeds, and from this point of view has already pretty nearly reached the limits permitted even with the use of the best steel available. The writer shows, however, that these limits of loads and speeds may be materially reduced by a new method of construction of the turbine disks, based on the use of shrinking on in hub construction.

The writer starts by investigating the conditions under which the last disk of the turbine delivers the desired amount of power when rapidly rotating. While the absolute velocity V of the steam as it leaves every other disk may be high without inconvenience, because the energy which it represents is to a large extent recovered in the next disk, this does not apply to the case of the last disk, because there this velocity constitutes a loss (exhaust loss) the value of which it is well to know.

Assume a turbine which delivers 15,000 hp. at 3000 r.p.m. with an hourly consumption of 52,500 kg. of steam per hour. When expanding into a vacuum of 96 per cent, which is now common practice, this amount of steam represents a volume of 1,620,000 cu. m. and hence the last disk of the turbine has to handle 450 cu. m. (15,885 cu. ft.) per sec.

Let D_m = the average diameter of the disk in meters
S = surface covered by the blades of the disk
v = average tangential velocity of the blades
V' = relative velocity of steam at exhaust, Fig. 14
V = absolute remaining velocity of steam at exhaust
V_a = axial component of V' and V.

The condition is that $S \times V_a = 450$.

The length of the blades cannot usefully exceed one-sixth of the average diameter of the disk. If this maximum value be here adopted the preceding condition may be written as

$$D_m^2 \cdot V_a = 860$$

The ratio V_a/V' depends on the shape of the blades. The writer considers in this connection the three values of 0.5, 0.6, 0.7, of which the last seems to be the limit of what can be done. Once this ratio has been selected, all that is necessary is to select the value of D_m, in order to determine the velocities v, V_a, V', V and the exhaust loss $U_r = V^2/g$. If we take a kilo-

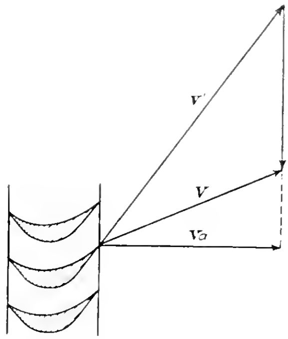

FIG. 14 DIAGRAMS OF VELOCITIES AT EXIT FROM DISK

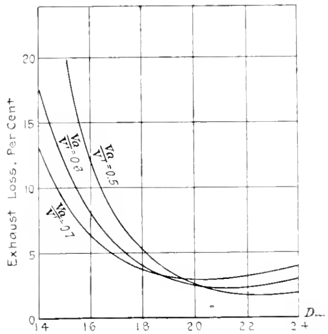

FIG. 15 GRAPHICAL REPRESENTATION OF THE MAGNITUDES OF EXHAUST LOSSES

gram (2.2 lb.) of steam assumed to be initially at 12 kg. pressure and 325 deg. cent. temperature and to contain an amount of energy equal to 95,000 kg-m., then the quotient $U_r/95{,}000$ represents the losses at the exhaust in percentage of energy initially available. The results of the computations carried out with various values of D_m are given in Table 3, and graphically expressed in Fig. 15. From these data it appears that it would have been good practice to give to the last disk of a turbine a diameter of from 2 m. to 2.2 m. Further, without making the consumption excessive D_m could be made 1.8 m. These values would permit the utilization in the last disk of one-fourth of the total energy available and bring us to a turbine with a comparatively small number of disks, for example, four, if all disks are of the same diameter.

As regards the hub C of such a disk, one must bear in mind that the diameter D = 1.4 m. (Fig. 16) and that the load uniformly distributed over its periphery amounts to about 750 tons due to the action of the centrifugal force on the blades and on the rim which encloses them. It is easy to see that

...ch loading conditions could not be applied in the case of a disk rotating at 3000 r.p.m. and built up of a single forging (hub and blade in one piece—as is the standard practice today), because such stresses would produce an excessive fatigue in the metal.

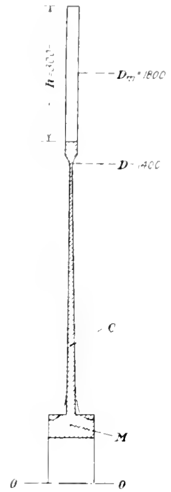

FIG. 16 SECTION OF THE LAST DISK WITH BLADES

The writer presents, therefore, a novel solution for the problem of disk construction based on the employment of shrunk-on collars on the hub.

A disk with a central bore comprises a body C (Fig. 16) and a hub M having parallel faces. This hub in itself is really a first disk of constant thickness having a low tangential velocity and acting as a basis for the radial stresses developed in the body C.

The body C and the hub M are usually connected by fillets which greatly reduce the harmful influence of reëntering angles, but these fillets may be made of quite small diameter on condition that they are located in a region of reduced stresses, it being quite easy to create such a region by a slight, purely local correction in the shape of the disk.

From this the writer proceeds to the discussion of the calculation of disks of uniform thickness. He uses a formula given by Anspach and Stodola, namely,

$$t=a+\frac{b}{r^2}-\frac{13}{32}Ar^2 \qquad [1]$$

$$t'=a-\frac{b}{r^2}-\frac{7}{32}Ar^2 \qquad [2]$$

in which t and t' are respectively the radial and tangential stresses present in the metal at a distance r from the axis of the disk. $A=\omega^2\frac{\delta}{g}$ is the product of the mass of a unit of volume of metal by the square of the angular velocity, while a and b are constants determined by the limiting conditions.

If r be expressed in meters and if $\frac{\delta}{g}=800\times 100^{-6}$ (for steel), then the main stresses t and t' may be expressed in kilograms per square millimeter by the preceding equations.

As regards disks of variable thickness, making one piece with the hub, their investigation is based on the use of two fundamental equations with three variables, these variables being, for example, the main stresses t and t' and the thickness z of the disk. Because of this, some additional arbitrary relation must be assumed in order to make possible the solution of these equations. The equations are as follows:

$$Ar+\frac{dt}{dr}+\frac{t}{z}\frac{dz}{dr}=\frac{t'-t}{r}$$

$$4\frac{dt'}{dr}-\frac{dt}{dr}=\frac{5}{r}(t-t')$$

TABLE 3 RESULTS OF CALCULATIONS WITH VARIOUS VALUES OF D_m

D_m		V_a	Exhaust loss for $\frac{V_a}{V'}=0.5$	$\frac{V_a}{V'}=0.6$	$\frac{V_a}{V'}=0.7$
			Per cent	Per cent	Per cent
1 4	220	439	37.3	17 5	13.1
1 6	251	356	11 9	8 15	6 5
1 8	282 5	265	5 43	4 03	3 78
2.0	314	215	2 67	2 52	2 96
2 2	345 5	178	1 78	2 34	3 17
2 4	377	149	1 95	2 89	3 92

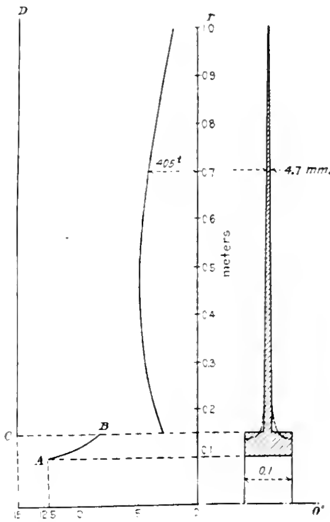

FIG. 17 SECTION OF ORDINARY DISK

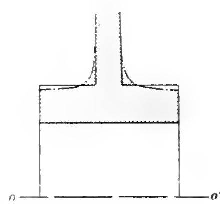

FIG. 18 HUB OF WRONG DESIGN, OF EXCESSIVE LENGTH

The solution of the auxiliary relation is actually limited by the fact that our knowledge is not always sufficient to enable us to carry out these computations. Nevertheless a good many examples which may be utilized in this conection are found in the works of Anspach and Stodola. The trouble is that even if various equations make it possible to arrive at certain results, these results are not always equally good, and one has to ask oneself which of the relations is the best. This question is of basic importance for practical purposes and the writer claims to be able to make an addition to the fund of knowledge given by the two investigators cited above.

A priori the best ratio is such as would at all points give to the two main fatigue values as nearly as possible approaching the limit F, a limit which should never be exceeded. In this way the utmost utilization of the metal is secured. This ratio is as follows:

$$t - t'/4 = F$$

and it shows that the radial fatigue (which expresses the proportional elongation) is constant and equal to the assumed

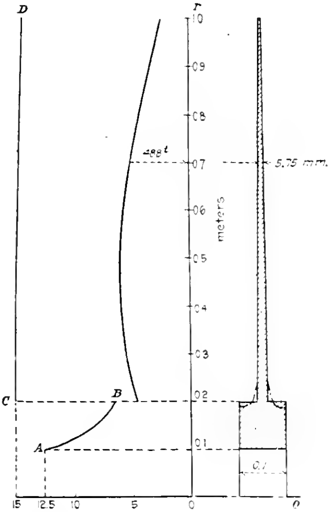

FIG. 19 SECTION OF DISK WITH REINFORCED HUB

limit F. The tangential fatigue, always quite small in the neighborhood of the hub, grows with great rapidity along the radius and tends toward the same value F. The comparison of the results thus obtained with those which follow from the other physical relations confirms the fact that the condition of constant radial fatigue leads to the selection of the highest values for such peripheral loads and speeds that can be actually used.

Let f'_o be the tangential fatigue of the metal at the junction of the body of the disk and the hub. If we write

$$\frac{4}{15}(F - f'_o)\, r_o = p$$

$$\frac{4}{3} F = q$$

the preceding condition leads to the following formulæ:

$$t = q - \frac{p}{r} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

$$t' = q - \frac{4p}{r} \quad \ldots\ldots\ldots\ldots\ldots\ldots [4]$$

$$\frac{1}{A} L(\ldots) - \frac{r^2}{q^2}\left(t - \frac{q}{2}\right) - \frac{p^2}{q^3} L(rt) = C^{te} \quad \ldots\ldots [5]$$

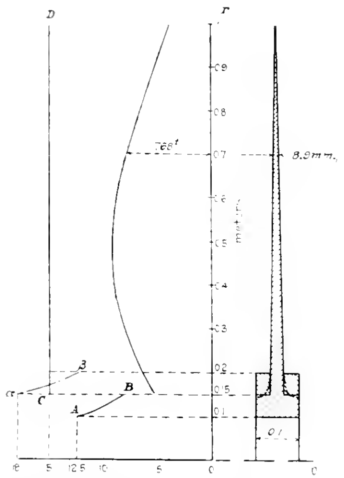

FIG. 20 SECTION OF DISK WITH HUB EQUIPPED WITH COLLAR (CURVE α β SHOWS FATIGUE IN COLLAR)

It in this last equation one makes $t = t'$ and hence $p = 0$, then, as may be proved easily, the equation reduces to the well-known formula of equal resistance disks, namely,

$$L\frac{z}{z_o} + \frac{A}{2t}(r^2 - r_o^2) = 0$$

The third item of the first member of this equatiou can be neglected under ordinary conditions, so that the equation takes the following practical form:

$$L(zt^4) + A\frac{r^2}{p^2}\left(\frac{3}{2}q - t\right) = C^{te}$$

Formulæ [1] and [2] on one hand, and [3] and [4] and [5] on the other, are sufficient for handling all numerical examples. As a rule, a large coefficient of safety should be provided in the selection of a value for F.

The use of shrunk-on collars on the hub makes it possible to extend materially the actual limits of stresses and peripheral velocities. To prove this the writer investigates the three disks shown in section by Figs. 17, 19 and 20. The hubs in Figs. 17 and 19 are of the usual type and differ in height according to the radius. The hub in Fig. 20 is similar to that in Fig. 17, but equipped with collars which raise its volume to that of Fig. 19.

All three are of the same width (100 mm.), same bore (200 mm.) and the same speed (3000 r.p.m.).

The writer selects for F a value of 15 kg. for the body of the disk, the steel used having the characteristics $R = 90$ kg., $E = 60$ kg., elongation 15 per cent. The fatigue in the bore of the hub is limited to 12.5 kg. because of the additional local stresses due to the presence of the key and also in view of the grave nature of accidents that might occur as the result of a crack in the hub. For the disk collars shown in Fig. 19 the maximum fatigue of 18 kg. would be moderate, because the presence of latent stresses is but hardly likely in these pieces of uniform thickness, and for them may be used a steel having

an elongation slightly lower than that of the disk and a tensile strength of, say, 100 kg.

Disk Shown in Fig. 17. Assume that in the bore $t = 0$ and $f' = t' = 12.5$. The constants a and b of Equations (1) and (2) are then found to be as follows: $a = 6.5$ and $b = 0.62$. These equations give us the stresses t and t' and the main fatigues $f = t - t'/4$ and $f' = t' - t/4$ of the hub along various radii.

Only the greater of these two main fatigues is of interest, namely f', the value of which is given by the curve AB. At the periphery of the hub where $r = 0$ or 0.15, it is found that $f' = 8.1$ kg. and $t = 3.03$.

In passing now to the body of the disk, it is found that the circular fibers in proximity to the hub and disk undergo the same elongation and are therefore subject to the same fatigue. The condition $f'_o = t' - t/4 = 8.1$, together with the arbitrary relation $F = t - t'/4 = 15$ kg. (straight line CD), determines the magnitudes of t and t'.

The radial stress thus found, viz., $t = 18.16$ kg., must be equal to the stress 3.03 kg. in the hub at its periphery, and hence the thickness z at the origin of the body of the disk is:

$$z = 100 \times 3.03 / 18.16 = 16.7 \text{ mm.}$$

Equations [3], [4], and [5] become then respectively:

$$t = 20 - 0.276\ r$$
$$t' = 20 - 1.101\ r$$
$$\log (zt') + 0.086\, r^2\, (30 - t) = 6.281$$

These equations completely determine the disk and the tensile stresses present therein. The load permissible at the periphery of the disk for a radius r is $2\pi rzt$ tons (the heavy-line curve, unit abscissa equal to 100 tons).

In the particular case considered above, with $r = 0.7$, the above equations give $t = 19.605$ kg., $z = 4.71$ mm., and 405 tons as the limit peripheral load. This load is considerably below the 750 tons which was thought to be necessary. The first thought would be to increase all thicknesses in the ratio 750/405 in order to obtain the desired resistance, but a simple scale sketch of the hub shows that this cannot be done because such a sketch makes it patent that the external parts are incapable of lending real support to the radial stresses in the disk, as shown by Fig. 18. Other stresses likewise limit the permissible length of the hub; thus one cannot with impunity increase indefinitely the turbine shaft, this latter being all the time under load and subject to rapid rotation (cp. *Revue de Mécanique*, June 1903).

Disk Shown in Fig. 19. One might attempt, in order to increase the resistance of the hub, to increase its height in the radial direction. As a matter of fact, the increase in the resistance amounting to about 20 per cent is secured through doubling the height of the hub, but such an increase of resistance is still quite insufficient and it cannot be increased further by employing a still higher hub.

Disk Shown in Fig. 20. The reason why fatigue cannot be materially reduced by increasing the height of the hub appears from an examination of curve AB in Fig. 19. This is because the added metal does not perform any work. Its maximum fatigue remains between the limits 6.5 kg. and 8 kg., and does not exceed that due to the centrifugal force of the hub structure itself.

The writer had the idea of substituting for this metal, which is only poorly utilized, metal which would work at its maximum efficiency. This result can be secured by adding to the hub of Fig. 17 collars placed with an initial, properly regulated compression. (Cf. British Patent No. 11849, in the year 1917.) The diagram in Fig. 20 shows that since metal added in the above manner is subject to a fatigue of from 12 to 18 kg., the peripheral load which may be applied to the disk at the radius, equal to 0.7 m., is as high as 768 tons.

In this case the compression stress exerted by the collar on the hub is 3.94 kg. and the thickness of the disk at its origin is 31.5 mm.

Still better results could be obtained by means of superimposed collars.

There was an impression that the present lack of certain special steels might hinder the construction of turbines having a large specific output. The preceding discussion shows, however, that when judiciously employed, ordinary good steel is amply sufficient for all present needs. (*La turbine à vapeur de grande puissance spécifique et les disques à moyeu fretté*, Maurice Delaporte, *La Technique Moderne*, vol. X, no. 3, March 1918, pp. 126-129, 7 figs., *tpA*)

Testing Materials

SOME EXPERIMENTS ON NOTCHED BARS, Captain Philpot. The paper describes a large number of experiments, the primary object of which was to obtain suitable dimensions and shape for a round notched-bar test piece, which could be used in acceptance tests on heat-treated steels in place of the standard square test piece. Under present conditions the pressure on milling and shaping machines is such that it appeared desirable, if possible, to remove the machining of notched-bar test pieces from such machines, and the first object in view when the experiments were started was to obtain a type of test piece which could be produced entirely by machining in an ordinary lathe.

Briefly put, Captain Philpot has met with considerable success, and a round test piece has been evolved which fulfils the conditions with sufficient accuracy for the purpose in view, the test piece being produced entirely by machining in a lathe, the notch being made by turning in an eccentric mandrel. This eccentric mandrel, however, has one disadvantage, in that it must turn through 360 deg., and the machining of the test piece takes place during but about 24 deg. of this motion. This objection, however, is partly overcome by mounting four test pieces in the mandrel, but an alternative method has been devised in which the notches in the round test piece can be milled or shaped, in place of turning them in the eccentric mandrel.

The experiments naturally carried Captain Philpot to other considerations than the mere round test piece, and the following conclusions which he came to indicate fairly well their nature:

1 Round test pieces (of types illustrated in the original paper) are sufficiently good approximations to the standard square test piece for use in acceptance tests on steel where facilities for machining the square test piece are lacking or insufficient.

2 Notched-bar test pieces, with relatively large radii at the roots of the notches, are insensitive, and are therefore unsatisfactory.

3 The tensile test, even where an extensometer is used, does not give any satisfactory criterion for detecting the condition of the material, which gives low values on the notched-bar tests.

4 The notched-bar test, made on a pendulum testing machine, is not *essentially* an impact test.

5 The notched-bar test may be made in either the Charpy or the Izod pendulum machines, and should give similar values except for very tough specimens. This similarity could prob-

ably be increased even for the higher values if the span for the 10-mm.-sq. test pieces were made 44 mm. instead of 40 mm., or the length of the Charpy specimen reduced, so that the specimens which were not entirely broken through were bent to the same included angle as in the Izod machine.

A point of importance brought out in the discussion was the view of the practical man of the value of the impact test. The matter was first raised by Commander Jenkins, who contended that the impact value of a steel has no direct value in designing, for instance, a crankshaft, and that we do not understand the relationship between elongation and impact value in regard to the factors which really govern the strength and the useful properties of a steel in a crankshaft. He thought it possible that elongation was some index of the fatigue range, and that probably the Izod figure was some indication of the rate at which minute cracks will extend in the shaft. At the same time he thought it was safe to assume that a high Izod test had a value.

Dr. T. E. Stanton said that the few cases at the National Physical Laboratory during the past four or five years in which failure had occurred through faulty heat treatment, were shown definitely by the impact test. He did not think the mere fact that one only had a lathe need prevent the use of the square test piece, and he sketched a device used at the National Physical Laboratory which enabled square specimens to be prepared by boy labor in twenty minutes.

Mr. H. W. Dickenson called attention to the fact that the bulk of Captain Philpot's work was with nickel-chrome steels. That fact should be borne in mind, because the impact test did not, in the same precise way, pick out the undesirable variations in the heat treatment when dealing with carbon steel as it did with nickel-chrome steels. His firm used the round test piece, and in the test house and workshops a preference was expressed for it. It was found to be easier to machine and easier and quicker to make. However, the trouble was that the impact test did not enable us to tell from the microstructure the quality of the steel. Take a piece of nickel-chrome steel, oil-harden it at 1000 deg. cent., temper it at 620 deg., and quench in water; take another piece of steel from the same bar and oil-harden it at 800 deg., quench at 620 deg., and very slowly cool, and very different results would be obtained. Most of them, a few years ago, would have said the second piece would give a good steel and the first one not, but the Izod test would give, say, 50 ft-lb. for the first one, while the second one, which gave a beautifully fine grain structure, would show about 15 ft-lb. He would not attempt to explain what it was that caused the difference, although he had a feeling that it was connected with the bonding between the crystals.

Mr. A. A. Remington did not think the author's round test piece was any improvement on the standard square piece from the point of view of enabling the properly heat-treated specimen to be sorted from the improperly treated one. He did not think the round test piece was easier to machine. So far as the value of the test piece was concerned, he contended that it represented the testing of materials under abnormal conditions. While all engineering structures had shoulders and corners, they were not usually designed so that they ripped right across at one blow. What it was desirable to know was the sort of notch or shoulder that could be put with safety in a material of a known tensile strength without risk and failure by fracture or fatigue. While the notched-bar test gave some information, the correlation between it and what the designer might safely put in was not very obvious to him.

Mr. T. Flather agreed with the views put forward by Mr. Remington. He had always felt that as far as possible physical tests should follow the definite requirements of the engineer and the designer; the notched-bar test, whatsoever its form, did not do so. What was there to prevent the adoption of an impact test piece which, while it had no notch on it, approximated very nearly to some of the things that were required in engineering practice?

Dr. W. H. Hatfield, speaking on the same point, said that if the tests were applied to carbon as to nickel steels, the carbon steels would be shown to be very brittle. Clearly, there was an explanation, and the obvious one was that a steel of 10 ft-lb., provided its elastic limit, yield, maximum stress, reduction of area and elongation were all right, was not a brittle steel. He would undertake to fly to Paris and back next week in an aeroplane that had a crankshaft with an impact value not exceeding 10 ft-lb. The fact was that large tonnages of steel used for the most vital purposes had values which would shock some people, yet these steels were faithfully fulfilling their functions under most stringent conditions; hence they could not be brittle. He had examined many failures, and had met with steels that had failed badly which had an impact value of 60 ft-lb. (Paper before Society of Automobile Engineers (British), read on April 10, 1918; abstracted through *The Engineer*, vol. 125, no. 3251, April 19, 1918, p. 338, *eA*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

Recent Gifts to the Engineering Societies Library

DURING the past twenty years the Westinghouse Electric & Manufacturing Company and the General Electric Company have collected a valuable library of some nine thousand volumes on electricity. The collection was intended especially for use in patent searches, and is particularly rich in patent material. Files of all the principal patents relating to electric light and power issued by America, England, France and Germany are present, together with copies of the patents owned or controlled by the two companies. Another feature, and one of unusual value, is a series of volumes containing the records of the important adjudicated patent causes of these companies and their predecessors during the past twenty-five years, and forming a storehouse of electrical history. There are also files of about one hundred electrical periodicals.

It is a pleasure to announce that this collection has now been presented by the owners to the Engineering Societies Library. This gift, which was arranged through Mr. Charles A. Terry, Vice-President, Westinghouse Electric & Manufacturing Company, and Mr. Charles Neave, Counsel, General Electric Company, was made with the thought that the collection would be useful to many engineers if housed in an easily accessible situation. It is an unusually valuable accession, for which the Library authorities are deeply grateful. The books have been transferred to the Engineering Societies Library, where they may now be consulted.

During April Mr. Jesse M. Smith presented nearly four hundred volumes and pamphlets selected from his private library, consisting of engineering periodicals and of records of patent causes with which Mr. Smith has been connected.

Mr. Putnam A. Bates has presented large portfolios containing a set of the drawings for the New York City fire-alarm system, which will prove interesting to engineers.

Dr. F. H. Newell has collected and presented a number of interesting publications relating to the Council of Engineering Societies on National Public Works, which was active in attempting to reform the policy governing the conduct of public works in this country during the eighties.

Space forbids the mention of many other gifts, but these have in nearly every case been of decided value to the Library, and have been appreciated also as evidence of friendly interest in its success. It is hoped that every member will bear the needs of the Library in mind and present from time to time any new or old engineering material which he can spare. General coöperation will bring to its shelves much scattered material which cannot be obtained in any other way.

Harrison W. Craver,
Director of Library.

BOOK REVIEWS AND NOTES

Kinematics of Machinery. A Text-Book on Mechanisms and Their Properties, with Many Practical Applications for Engineers and for Students in Technical Schools. By Arthur Warner Klein, M.E. McGraw-Hill Book Co., Inc., New York, 1917. 1st ed. Cloth, 6x9 in., 227 pp., 120 figs. and 7 folding plates. $2.50.

The first thirty-four pages of this book present the elementary ideas about motion, and the construction and operation of mechanism. Chapter IV explains the construction of displacement diagrams; Chapters V, VI and VII, constituting seventy-four pages, discuss the graphical determination of velocities; Chapters VIII, IX and X, of fifty pages, present graphical methods for finding accelerations. Chapter XII takes up the problem of force and mass reduction, that is, the determination of a mass assumed as concentrated at a given point in the mechanism which shall give an energy condition for the system equivalent to that existing before the mass was concentrated.

Appendix A elaborates a mathematical criterion for determining if an assemblage of links is a mechanism or not. Appendix B shows how to determine velocities and accelerations by polar diagrams.

The book presents the subject of kinematics of machinery from a mathematical rather than from the engineering standpoint. The author has elaborated very completely the instant-center method of analysis, reaching a culmination in its application to governor-gear problems. This, of course, is a very narrow field, and as all useful mechanism tends toward simplicity rather than complexity, most of its problems can be solved with quite elementary analysis. Much of what is contained in the book was presented thirty years ago by Burmester in his Lehrbuch der Kinematik, but as the author says in his preface, "the study of mechanism has always been a fascinating one for mechanical engineers," and we believe the real student of mechanism will find some stimulus here in reviewing his old ideas in the light of the original contributions of the author.

Alton L. Smith.

Mechanical Laboratory Methods. The Testing of Instruments and Machines in the Mechanical Engineering Laboratory and in Practice. By Julian C. Smallwood, M.E., Fellow, Johns Hopkins University, Mem.Am.Soc.M.E. D. Van Nostrand Co., New York, 1918. Second edition, revised and enlarged. Flexible cloth, 5x7¼ in., 399 pp., 114 illustrations. $3 net.

A second edition of this compact work on the broad principles of experimental apparatus and methods having been called for, the author has taken the opportunity afforded to make certain additions to the text. These include matter on the testing of condensers, feedwater heaters, ammonia absorption and compression refrigerating systems, and the horsepower output of electric motors; steam and ammonia tables, a Mollier diagram and tables of areas of circles, four-place logarithms and densities of water. The section on instruments has been enlarged to comprise recording apparatus, the treatment of valve setting and steam-engine testing has been extended and improved, and a section on hygrometry has been added. In the previous edition there appeared in print for the first time descriptions of a number of testing methods, among

them being a method of setting the slide valve by the Bilgram diagram, the application of the method of least squares to indicator-spring calibration, methods originated by the author for testing indicator-drum motion and reducing wheels, etc.

Finding and Stopping Waste in Modern Boiler Rooms. Compiled by George H Gibson, Mem Am Soc.M.E., assisted by Capt. Percy S. Lyon, Jun.Am.Soc.M.E. Harrison Safety Boiler Works, Philadelphia, Pa., 1918. Linen, 4¾x7 in., 270 pp., 213 illustrations $1 net.

This valuable and timely reference manual, designed "to aid the owner, manager and boiler-room operator in securing and maintaining plant economy," is a compilation of statements, tables and charts from a wide variety of sources, among which are the TRANSACTIONS of the Society, the publications of the U. S. Bureau of Mines and the files of technical periodicals. The work is divided into five sections dealing respectively with fuels, combustion, heat absorption, boiler efficiency and boiler testing, and boiler-plant proportioning and management. It is stated that only such material as is supported by the results of experiments and tests has been selected, and that statements of different authorities have been carefully compared and each source of information checked against others.

Efficiency Methods. By M. McKillop, M.A., and A D. McKillop, B.Sc. (Eng.), C.E. D. Van Nostrand Co., New York, 1917. Cloth, 5x7 in., 215 pp., 6 illustrations. $1.50 net.

A brief but reasonably comprehensive statement of the principles and aims of modern American methods of shop management, which the authors believe should be brought to the attention of all those with position and influence in British industry. The information given has been obtained from authoritative literature on the subject and from observation of the Taylor system in operation, and the book is written from the standpoint of those who have worked under that system and have been very favorably impressed with its effectiveness.

Theories of Energy. By Horace Perry. G. P. Putnam's Sons, New York and London, 1918. Cloth, 5x7¼ in., 231 pp., 4 diagrams. $1.75 net.

During the past twenty years the author has made a study of the various manifestations of energy, and the results of his thoughts and investigations are set forth in this book. A new theory of color is advanced which, it is stated, clears up a number of points not previously understood.

Agricultural Bacteriology. By H. W. Conn. 3rd ed. Revised by H. J. Conn. A Study of the Relation of Germ Life to the Farm with Laboratory Experiments for Students. Microorganisms of Soil, Fertilizers, Sewage, Water, Dairy Products, Miscellaneous Farm Products and of Diseases of Animals and Plants. P. Blakiston's Son & Co., Philadelphia (copyright 1918). Cloth, 6x8 in., 357 pp., 63 illus. $2.

The third edition has been brought up to date by the inclusion of the advances in bacteriological knowledge since the previous edition.

Aircraft Mechanics Handbook. By Fred H. Colvin. 1st ed. A Collection of Facts and Suggestions from Factory and Flying Field to Assist in Caring for Modern Aircraft. McGraw-Hill Book Co., Inc., New York, 1918. Flexible cloth, 5x7 in., 402 pp., 193 illus., 28 tables. $3.

A manual of the best practice in inspecting, adjusting and repairing airplanes, prepared for use by the machinists and riggers who are now being trained. Describes the construction, erection and testing of the planes, the various engines in use and the methods of caring for them. An account of the Canadian training camp at Borden is also given. Useful tables and a glossary are included.

Artificial Dye-Stuffs. B[illegible] Ram[illegible] Curtis Weston. Their Nature Manufacture and Uses. E P Dutton & Co New York, 1917 Cloth 6x9 in., 212 pp., 24 illus $1.60

A brief introductory work on the artificial dye-stuff industry, written for students and business men with little knowledge of organic chemistry, in which the industrial processes of the manufacture of dyestuffs and the nature of the substances used are explained at some length.

Aviation Chart. By Victor W Pagé Location of Airplane Power Plant Troubles Made Easy The Norman W Henley Publishing Co., New York 1918 Paper, 32x46 in $.50

A large chart outlining all parts of a typical airplane power plant, showing the points where trouble is apt to occur and suggesting remedies for the common defects. Intended especially for aviators and aviation mechanics on school and field duty.

Coal Gas Residuals. By Frederick H. Wagner. 2nd ed Revised and enlarged McGraw-Hill Book Co., Inc., New York 1918 Cloth 6x9 in., 244 pp., 45 illus., 12 pl. (10 folded), 7 diag., 32 tab. $2.50

The chief additions to this edition discuss the process of tar distillation and tar products, and give further information on the product derived from spent oxide, the production of nitric acid, naphthalene, benzol and toluol. A chapter on the manufacture of sulphuric acid from spent oxide has also been added, and the typographical errors in the first edition have been corrected.

Cold Drawn Steel. Issued by the Peerless Drawn Steel Co Bar Weights of Rounds, Flats, Hexagons, and Squares; Weight Tables for Plates, Metric Conversion Tables (Cover Title—Book of Weights). The Peerless Drawn Steel Co., Massillon 1918 Flexible leather, 5x8 in., 145 pp., 52 tab. $3.

Instead of giving only the weight per foot of steel bars of various sizes, this book gives the totals for bars of all the usual lengths in feet. A number of other useful tables are added.

Complete List of Base Prices, Differentials and Extras on Iron, Steel and Non-Ferrous Products. Fixed under Government Supervision. Penton Publishing Co., Cleveland (copyright 1918) Paper 6x8 in., 42 pp $2

A convenient summary of the Government prices. Prepared by the *Iron Trade Review* and presented to subscribers to that journal.

Creating Capital. By Frederick L Lipman Money-Making as an Art in Business Houghton Mifflin Co., New York 1918. Cloth, 5x7 in., 71 pp., $0.75.

Higher Education and Business Standards. By Willard Eugene Hotchkiss. Houghton Mifflin Co., New York, 1918 Cloth, 5x7 in 209 pp. $1.

Two essays delivered at the University of California on the Weinstock Foundation, established for the discussion of the various phases of the moral law in its bearing on business life under the new economic order.

Electrical Measurements. By O. J. Bushnell and A. G. Turnbull. A Practical Handbook Covering the Design and Construction of Measuring Instruments and their Uses in Measurement of Current, Resistance, and Commercial Power, with Special Reference to Watt-hour and Maximum Demand Meters. American Technical Society Chicago, 1914. Cloth, 6x8 in., 171 pp., 139 illus., 2 pl. $1

The authors' aim has been to supply an adequate description of the instruments and methods used for the measurement of electrical energy, and to show by diagrams exactly how meters should be connected under all conditions.

Electrodynamic Wave-Theory of Physical Forces. By T. J. See Announcing the Discovery of the Physical Cause of Magnetism, of Electrodynamic Action, and of Universal Gravitation Vol. 1, Bulletins 1 to 6 inclusive. Thomas P. Nichols & Son Co., Lynn, Mass., 1917 Paper, 10x12 in., 158 pp., 21 diag., 4 pl., 1 chart, 6 tab. (1 folded) $7

In these bulletins Dr. See presents his hypothesis that mag-

[illegible] action and universal gravitation are [illegible] propagated with the velocity of light through the free ether and at slower rates through solid masses. The author believes that his investigations have finally solved the problem of the nature and mode of propagation of physical forces.

Field Artilleryman's Guide. [illegible] Gun [illegible] Hoecker. Prepared for the Officers of the 108th [illegible] Field Artillery. 2d ed. P. Blakiston's Son & Co., Philadelphia (copyright [illegible]). Cloth, 4x7 in., 381 pp., 108 illus., [illegible] pl., [illegible] tab. $1.75.

A pocket guide intended to serve the immediate needs of field artillerymen in the United States Army by presenting the fundamentals of their duties.

Forging. By John Jernberg. Manual of Practical Instruction in Hand Forging of Wrought Iron, Machine Steel and Tool Steel, Drop Forging; and Heat Treatment of Steel, Including Annealing, Hardening and Tempering. American Technical Society, Chicago, 1917. Cloth, 6x8 in., 131 pp., 206 illus., 2 pl., 3 tab. $1.

A concise account, intended primarily for students. Describes the methods and tools used in hand forging, as well as the usual shop practice in hardening, annealing and tempering steel.

Galvanizing and Tinning. By W. T. Flanders. A Practical Treatise on the Coating of Metal with Zinc and Tin by the Hot Dipping, Electro Galvanizing, Sherardizing and Metal Spraying Processes, with Information on Design, Installation and Equipment of Plants. David Williams Co., New York, 1916. Cloth, 6x9 in., 350 pp., 142 illus., 3 charts, 5 tab. $4.

Discusses the various processes in a practical way, describing the machinery, materials and operations in detail. Intended as a guide in the installation and operation of galvanizing and tinning plants.

Handbook of Hydraulics for the Solution of Hydraulic Problems. By Horace William King. 1st ed. McGraw-Hill Book Co., New York, 1918. Flexible cloth, 4x7 in., 424 pp., 91 illus., 112 tab., 2 diagrams. $3.

The author has attempted to simplify the work of the hydraulic engineer by studying critically the empirical formulæ which have been devised and selecting those which are of value. These are presented with a description of their limitations and are accompanied by the necessary tables of coefficients. The twofold purpose of securing an accuracy consistent with the best experiments and of simplifying calculations has been kept in mind throughout the book.

Internal-Combustion Engine Manual. By F. W. Sterling. 4th ed. R. Beresford, Washington, 1917. Cloth, 6x10 in., 168 pp. $2.

This manual, representing the course on internal-combustion engines given at the U. S. Naval Academy, has been rewritten, enlarged and brought up to date. It now covers the theory and practice of these engines without including mathematical demonstrations and formulæ. Particular attention is given to the engines used by the Navy and to aviation engines.

Manual of Military Aviation. By Hollis Leroy Muller. Prepared for the use of Personnel of Aircraft Troops of the Army, National Guard and Reserve Corps, Members of Military Training Camps, and Airmen in General. George Banta Publishing Co., Menasha, Wis. (copyright 1917). Cloth, 5x8 in., 308 pp., 38 illus. $2.50.

Contains the theoretical information necessary for efficient military aviation service. Intended for use as a textbook and as a reference work.

Machine Shop Practice. By William L. Hartman. D. Appleton & Co., New York, 191[illegible]. Cloth, 5x7 in., [illegible]47 pp., 141 illus., 4 pl., 10 tab. [illegible]

A presentation of the elementary principles of machine-shop practice, intended for the instruction of beginners. Mathematical calculations are confined to the use of simple arithmetic.

Mechanics of the Household. By E. S. Keene. A Course of Study Devoted to Domestic Machinery and Household Mechanical Appliances. McGraw-Hill Book Co., New York, 1918. Cloth, 6x8 in., [illegible] pp., 273 illus., 11 tab. $2.50.

This book is intended to be a presentation of the physical principles and mechanism employed in the equipment that has been developed for domestic convenience. Equipment for heating, ventilating, water supply, sewage disposal, lighting, etc., is described.

Metallurgical Calculations. By Joseph W. Richards. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 7x10 in., 692 pp., tab. $5.

A convenient one-volume edition of the work, in which errors occurring in earlier ones have been corrected and new physical and chemical data have been added.

Power Stations and Transmission. By George C. Shaad. A Comprehensive Treatise on Electric Power-Station Equipment, Design and Management, and the Erection and Maintenance of Proper Transmission Lines. American Technical Society, Chicago, 1917. Cloth, 6x8 in., 180 pp., 50 illus., 3 pl., 10 tab. $1.

Presents concisely the important features of the topic. The treatment is largely descriptive and non-mathematical.

The Principles, Operation and Products of the Blast Furnace. By J. E. Johnson, Jr., 1st ed. McGraw-Hill Book Co., New York, 1918. Cloth, 6x9 in., 551 pp., 173 illus., 23 tab. $5.

A thorough, detailed discussion of the operation of the blast furnace, including both the theoretical principles and the practice of the present day. Completes the author's treatise on the manufacture of pig-iron, begun in his work entitled Blast Furnace Construction.

The Principles of Sanitary Tactics. By Edward Lyman Munson. A Handbook on the Use of Medical Department Detachments and Organizations in Campaign. George Banta Publishing Co., Menasha, Wis. (copyright 1917). Cloth, 5x8 in., 305 pp., 13 maps, including two folded maps in cover. $2.15.

The author's desire has been to provide a text book which will standardize the methods of instructing line and medical officers in the tactical use of the sanitary service with troops in campaign, and will also give a thorough grounding in the fundamentals of sanitary tactics as a whole.

Radio Telephony. By Alfred N. Goldsmith. The Wireless Press, Inc., New York (copyright 1918). Cloth, 6x9 in., 247 pp., 226 illus. $1.25.

The author has attempted in this work to give a full description of present methods of radio telephony and of the various types of apparatus employed. The first systematic exposition of the subject to appear since 1907.

The Science of Management. By Frederick A. Parkhurst. Published by the Author, Cleveland (copyright 1918). Cloth, 6x9 in., 203 pp., 7 tab. $3.

A textbook prepared to accompany the author's course of thirty lectures, delivered during 1917-18 at the Case School of Applied Science.

A Short Handbook of Oil Analysis. By Augustus H. Gill. 8th ed., revised. J. B. Lippincott Co., Philadelphia, (copyright 1918). Cloth, 5x8 in., 209 pp., 9 illus.

This well-known manual is designed to provide a concise account of the methods of applying the usual physical and chemical tests to oils. The eighth edition has been revised, descriptions of some new forms of apparatus included and some minor tests and new methods added.

Technical Mechanics. By Edward R. Maurer. Statics and Dynamics. 4th ed., revised and enlarged. John Wiley & Sons, Inc., New York, 1917. Cloth, 6x9 in., 381 pp., 178 illus. $2.50.

A theoretical mechanics written for students of engineering, in which each subject discussed has a direct bearing on some engineering problem. The book thus differs from those commonly called theoretical mechanics, and is, on the other hand,

dissimilar to books commonly entitled applied mechanics. The fourth edition has in addition 176 more problems and the modification of the articles on axle reactions, efficiency of machines, hoists, gyrostats kinetics of plane motion, rolling resistance, kinetics of a body with a fixed point, and the dynamics of any motion of a rigid body.

Text Book of Advanced Machine Work. By Robert H. Smith. 4th ed. Revised and enlarged. Prepared for Students in Technical, Manual Training, and Trade Schools, and for the Apprentice and Machinist in the Shop. Industrial Education Book Co., Boston (copyright 1916). Cloth, 5x8 in., 648 pp., 680 illus., 44 tab. $3.

A continuation of the author's Principles of Machine Work. This volume treats of engine-lathe work, drilling and boring machines, grinding, planing, milling, gear cutting and tool making. Careful explanations are given in each case.

War Administration of the Railways in the United States and Great Britain. By Frank Haight Dixon and Julius H. Parmelee. Carnegie Endowment for International Peace, Division of Economics and History. Preliminary Economic Studies of the War. Oxford University Press, New York, 1918. Paper, 7x10 in., 155 pp. $1.

An account of the methods used in the two countries and of the results achieved prior to December, 1917, during the period when the American railways were voluntarily coöperating with each other. The authors present a simple narrative, without attempting to draw conclusions.

War-Time Control of Industry. The Experience of England. By Howard L. Gray. The Macmillan Co., New York, 1918. Cloth, 5x8 in., 307 pp. $1.75.

A summary of the development and status of governmental control of industry in Great Britain, arranged to show its successive stages. Part of the information was collected for the Commercial Economy Division of the Council of National Defense. The book concludes with a comparison of English and American experience.

The Petroleum and Natural Gas Register. A Directory of the Petroleum and Natural Gas Industries in the United States, Canada and Mexico. The Oil Trade Journal, New York, 1917-1918. Cloth, 9x12 in., 548 pp. $12.

This work is based on statements made by officials of the companies listed, and gives the usually needed information as to properties, capital stock, officers, etc. The price includes an annual subscription to the *Oil Trade Journal*, in each issue of which supplemental data are to be published.

LIBRARY ACCESSIONS

Airplane Building. List of books in collection of Brooklyn Public Library, January 1918. *Brooklyn, 1918.* Gift of Brooklyn Public Library.

Alcohol as a Source of Power. (South Australia. Dept. of Chemistry. Bulletin No. 8.) *Adelaide, 1917.* Gift of South Australia Dept. of Chemistry.

Apparent Dielectric Strength of Varnished Cambric. By A. E. Kennelly and R. J. Wiseman. Reprinted from *Electrical World*, Dec. 15, 1917. Gift of Massachusetts Institute of Technology, Electrical Engineering Dept.

Ascertainment of Machinery Values and Losses. Read before the Insurance Society of New York, Jan. 11, 1916. By John Hankin. Gift of Insurance Society of New York.

Bolivia, the Republic of—Official Information and Statistics, Summarized by Julio Zamora. *New York, n. d.* Gift of Bolivia, Minister of Foreign Relations.

California Railroad Commission. Opinions and Orders, Dec. 1, 1916-March 31, 1917. vol. XII. *Sacramento, 1917.* Purchase.

Chamber of Commerce of the United States of America. Year Book, 1917. *Washington, 1917.* Gift of Chamber of Commerce.

The Chemical Constitution of the Proteins. By R. H. A. Plimmer. Part 1, Analysis. Longmans, Green and Co., *New York, 1917.* Boards, 6 x 10 in., 174 pp., 7 illus., $1.80. Gift of the publishers.

Chemistry of Linseed Oil. By J. Newton Friend. *London, 1917.* Purchase.

Cotton Production and Distribution, 1916-17. U. S. Bureau of the Census, Bulletin 135. *Washington, 1918.* Purchase.

Curtiss Standard JN4-B Military Tractor. Handbook, 1917.

Curtiss Standard Model V-2 Aeronautical Motor. Handbook, 1917.

Curtiss Standard Model OX Aeronautical Motor. Handbook, 1918.

Curtiss Standard Model OX 5 Aeronautical Motor. Parts list. *Buffalo, 1917-18.* Gift of Curtiss Aeroplane & Motor Corporation.

Design and Construction of Industrial Buildings. By Moritz Kahn. *London, 1917.* Purchase.

Dust Explosions and Fires in Grain Separators in the Pacific Northwest. (U. S. Dept. of Agriculture. Bulletin No. 379.) *Washington, 1916.* Purchase.

The Examination of Milk for Public Health Purposes. By Joseph Race. John Wiley & Sons, Inc. *New York, 1918.* Cloth, 5 x 8 in., 224 pp., 4 illus., $1.75. Gift of the Publisher.

Factor of Safety of Wire Ropes Used for Winding in Mine Shafts. By J. A. Vaughan. Reprinted from the *Journal of the South African Institution of Engineers*, Nov. 1917. Gift of author.

Foaming of Boiler Waters. (South Australia. Dept. of Chemistry. Bulletin No. 5.) *Adelaide, 1917.* Gift of South Australia, Dept. of Chemistry.

Freight Handling and Terminal Engineering. Vol. 2; 3; Vol. 4, No. 1. *New York, 1916-18.* Gift of H. McL. Harding.

Fresh Water Biology. By Henry Baldwin Ward and George Chandler Whipple with a collaboration of a staff of specialists. John Wiley & Sons, Inc. *New York, 1918.* Cloth, 6 x 9 in., 1111 pp., 1547 illus., $6. Gift of the publisher.

The German Union of Technical and Scientific Societies. By Sir Robert Hadfield. *January, 1918.* Gift of Sir Robert Hadfield.

Gold Deposition in the Bendigo Gold Field, the Factors Influencing Australian. Advisory Council of Science and Industry. Bulletin No. 4. *Melbourne, 1917.* Gift of Advisory Council of Science & Industry.

Great Britain. Department of Scientific and Industrial Research Advisory Council. Report on the sources and production of iron and other metalliferous ores used in the iron and steel industry. *London, 1918.* Gift of A. D. Flinn.

Heat Treatment of High Speed Steel. By Garnet W. McKee. Ed. 3. *n. p. n. d.* Gift of Eclipse Fuel Engineering Company.

Heat Treatment of Steel in Gas Furnaces. By Garnet W. McKee. Ed. 4. *Rockford, Ill., 1918.* Gift of Eclipse Fuel Engineering Company.

Helicopter Flying Machine. By J. Robertson Porter. *London, 1911.* Purchase.

How Baltimore Manufacturers Can Do Business with the Government. Suggestions and Information. Gift of the Civic and Industrial Bureau of the Merchants and Manufacturers Association.

Hydraulic Turbines. I. P. Morris Company, Hydraulic Dept. Bulletin No. 4. The William Cramp & Sons Ship & Engine Building Co. *Philadelphia, 1915.* Gift of F. H. Rogers.

Hydrometric Surveys (Stream Measurements) for 1916. Canada. Department of the Interior. *Ottawa, 1917.* Gift of Department of the Interior.

Industrial Plant Construction. *Buffalo, 1918.* Gift of The John W. Cowper Company.

Industrial Research in Canada. By J. C. McLennan. *Toronto, 1916.* Gift of Royal Canadian Institute.

LA NAVE A MOTORE DIESEL. [illegible] By Giorgio Supino. *London*, [illegible]. Purchase.

L'INDUSTRIE DE L'ACIER EN FRANCE. By J. Tribot Laspière. *Paris*, 1916. Purchase.

LIQUEFYING AIR BY THE LINDE THROTTLE RELEASE VALVE AT ATMOSPHERIC PRESSURE AND THE PLACE PROCESS OF 4 STEP RELEASE WITH LIQUEFACTION AT THE CRITICAL PRESSURE. Both systems availing of the Joule-Thomson equation for expanding air without recoverable mechanical work. By J. F. Place. *Glen Ridge*, 1918. Gift of J. F. Place.

MAGNESIA ASSOCIATION OF AMERICA. Anniversary advertising portfolio of "85% Magnesia" 1917. *Philadelphia*, 1917. Gift of Association.

MECHANICAL EQUIPMENT OF BUILDINGS. Vol. II.—Power Plants and Refrigeration. By Louis Allen Harding & Arthur C. Willard. John Wiley & Sons. *New York*, 1916. Purchase.

MEMORANDUM RESPECTING THE QUALITY OF SPELTER SUITABLE FOR THE MANUFACTURE OF CARTRIDGE BRASS AND OTHER HIGH GRADE BRASS. By W. R. Ingalls. *New York*, 1917. Gift of author.

MERCHANTS' ASSOCIATION OF NEW YORK. Summary of laws and ordinances applying to streets and public places in the City of New York, April 15, 1916, and the duty of police officers and citizens in connection therewith. *New York*, n. d. Gift of Merchants' Association of New York.

MUNITION WORKERS, BOOK HELPS FOR. Gift of Brooklyn Public Library.

NATIONAL PHYSICAL LABORATORY. Notes on screw gauges by the staff of the gauge testing department. *Teddington*, 1917. Gift of National Physical Laboratory.

THE PHYSICAL CHEMISTRY OF THE PROTEINS. By T. Brailsford Robertson. N. Y. and Lond. Longmans, Green & Co., *New York*, 1918. Cloth, 6 x 9 in., 483 pp., 8 illus., $5. Gift of the publisher.

THE POWER COMPANY AND THE DISTRIBUTION OF ELECTRICAL ENERGY. By Wm. C. L. Eglin. (Supplement to Current News, April, 1917.) Gift of author.

THE PRESERVATION OF WOOD. By A. J. Wallis Tayler. *London*, n. d. Purchase.

PRODUCTION OF HIGH TEMPERATURE AND ITS MEASUREMENT. By E. F. Northrup. Reprinted from the Transactions of the Faraday Society, v. 13. Gift of Alfred D. Flinn.

REFRACTORY MATERIALS: THEIR MANUFACTURE AND USES. By Alfred B. Searle. *London*, 1917. Purchase.

REINFORCED CONCRETE CARGO STEAMSHIP "FAITH," THE LARGEST CONCRETE VESSEL AFLOAT. Gift of Portland Cement Association.

SCIENTIFIC RESEARCH IN RELATION TO COTTON AND THE COTTON INDUSTRY. Manchester, Provisional Committee on Research and Education for the Cotton Industry, 1917. Gift of A. D. Flinn.

THE SHIPBUILDER'S LIBRARY. BOOKS ON NAVAL DESIGN AND CONSTRUCTION TO BE FOUND IN THE BROOKLYN PUBLIC LIBRARY. August 1917. Gift of Brooklyn Public Library.

THE SYNTHETIC DYESTUFFS AND THE INTERMEDIATE PRODUCTS FROM WHICH THEY ARE DERIVED. Ed. 3. By J. C. Cain and J. F. Thorpe. *London*, 1917. Purchase.

THEORY OF THE SUBMARINE TELEGRAPH AND TELEPHONE CABLE. By H. W. Malcolm. *London*, 1917. Purchase.

THE SPRING MEETING

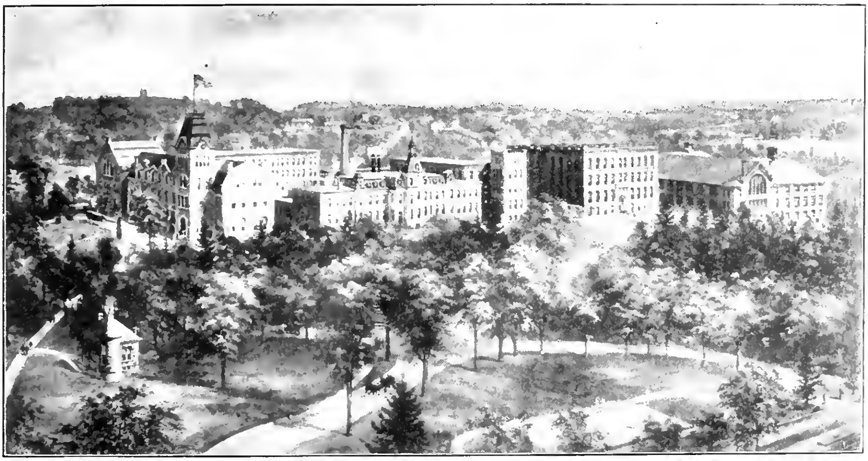
THE Spring Meeting of 1918 is destined to go down in the annals of the Society and to become generally known as "The Great Worcester Meeting." It was great in attendance, with a registration of 472 members and 514 guests, a total of 986—much the largest Spring Meeting of the Society; it was great in practical accomplishment in the interests of the Society and its work, particularly in relation to the war; and it was great in the good-fellowship and hospitality displayed by the citizens of Worcester and provided for with such admirable care by the members of the Local Committee.

It was very evident to those arriving that they were expected guests and that the people of Worcester were prepared to extend a royal welcome. Throughout the city, in every business window, was displayed an artistic placard bearing the emblem of the Society and announcing the convention. For days previous there had been articles on the Society and its meeting in the daily press, and it should be said in this connection that the publicity both before and during the convention, due to the effective work of the local Printing and Publicity Committee, was the most extensive the Society has ever received.

In the Hotel Bancroft, the headquarters, a large electric sign heralded the meeting, and at the registration desk every one received a handsome brochure and entertainment program issued by the local committee. The ballroom of the hotel was appropriately decorated, as shown in the view on the following page.

Professional sessions, however, were mainly held in the several large halls of the Worcester Polytechnic Institute, splendidly adapted for this purpose. Here the decorations were simple but effective, comprising the flags of the Allies. The opening session was in the large new gymnasium of the Institute, and on the first day of the meeting luncheon was served in the electrical engineering laboratories. These laboratories are large and extensively equipped, easily affording space for serving the four hundred or more in attendance at the first session. The Society was particularly fortunate in having these facilities, and it was a pleasure to the members to be able to spend so much time at the Institute, where inspection could be made of its laboratories, shops and general equipment. No small part of the pleasure was to be greeted there by Dr. Hollis, president of the Institute and former president of the Society.

The large attendance at the meetings was no doubt due in part to the fact that Worcester is the "center," as one speaker expressed it, "of a circle of 50 miles radius, in which is a population of 4,000,000 people," a large number of whom are engaged in the industries. It is convenient of access to many of our members. Through the coöperation also of the Boston Local Section, the Providence Engineering Society and the New York Section, delegations came to the meeting, which swelled the attendance.



Worcester Polytechnic Institute where the Members were Cordially Welcomed and Most of the Professional Sessions were Held

Professional Sessions

An account of the several sessions is given in this number of The Journal, and one, on The Economical Use of Fuel, resulted in so large an amount of contributed discussion of vital importance to the fuel question at the present time that it has been made a supplement to The Journal, issued as Part 2 of the present number. The spirit of the war and the service which the engineer must render, not only as a citizen, but because of his special attainments, pervaded the whole meeting. The papers at the New England Day Session on Wednesday very largely discussed war problems, and at the meeting on Emergency Technical War Training on Thursday there were ringing addresses which enthused the audience and impressed all with the responsibilities which must be assumed in preparing men for technical service. There were the usual technical papers on general subjects and an interesting session at the Norton Companies' plants, the latter relating to the housing of workmen and employees and work for the betterment of conditions existing among employees and of their relations to their firms.

BALLROOM OF HOTEL BANCROFT DECORATED FOR THE MEETING

SPRING MEETING ENTERTAINMENT

It was the evident purpose of the Local Committee at Worcester that, however restricted transportation facilities might be in the future, every one at the Worcester meeting, at least, should have an opportunity to ride. Special trolley cars were provided and owners of automobiles in the city freely contributed their machines so that every visitor was transported to or from the points which he wished to visit. Besides this, there were automobile trips for the ladies and the memorable all-day trip on Friday, which were enjoyed to the fullest extent.

While automobiling was a characteristic feature, it was, however, only incidental to the several social affairs which the Committee provided. These opened brilliantly on Tuesday evening, following the more formal proceedings at the hotel, by a reception at the Art Museum and a dance at the Woman's Club building adjoining, which is one of the fine club buildings of the country. This was the first affair of the kind ever held in the beautiful rooms of the Museum, and it made a most favorable impression upon every one as the initial event of the convention. Exquisite music was rendered by Boston opera players. Tuckerman Hall, where the dance was held in the Woman's Club Building, was attractively decorted with huge masses of peonies and roses. Dancing continued until a late hour and refreshments were served throughout the evening.

TRIP TO THE NORTON COMPANIES' PLANTS

On Thursday noon the members and guests were conveyed either by automobile or special train to the Norton Companies' plants, where a bountiful buffet lunch was served in Plant 6 dining room. Trips were projected for the afternoon to the model homes of the Norton employees at Indian Hill; to the company's farm gardens and to various departments of the manufacturing plants, especially that of the Norton Grinding Company, to witness a demonstration of grinding machines on Government work. The weather was rainy during the early part of the afternoon, so that these plans could not be fully carried out. Nevertheless, between showers several trips were made, and the afternoon was pleasantly spent.

It may be of interest to add that the large new athletic field and ball grounds, which were pointed out to the visitors, have since been dedicated by a large meet of the employees at which athletic games were held.

Coincident with the trips mentioned was the professional session, at which valuable information was given about the employees' service work of the Norton Companies, a report of which appears elsewhere in this number.

DELIGHTFUL EVENING AT THE WORCESTER COUNTRY CLUB

On Thursday evening was the garden party at the Worcester Country Club, the closing festivity. The location of the club, with its broad view of green slopes and foliage, is ideal, and the long evenings of daylight which we are now enjoying contribute greatly to the success of an evening party such as was here held. The club building has a large tiled terrace, where a buffet supper was served. The decorations were elaborate, and had been made under the direction of a Worcester architect, to give the effect on the terrace of an Italian garden, with well curb, statuary, and shrubbery and flowers, the latter massed against a temporary wall which had been erected on one side of the terrace or intertwined in trellises about the other three sides. Every service table bore a large bouquet of roses, and it should be said that the luncheon was admirably served, without crowding, although it was estimated that there was an attendance of 600 people. Music on the lawn was supplied by the well-known Reeves American Band of Providence, and later in the evening an orchestra in the main hall of the club supplied music for dancing.

Throughout the evening members gathered in groups about the verandas or on the lawn and enjoyed to the utmost the opportunity for a social time, and were unanimous in saying that it was one of the most successful social events they had ever attended.

ENTERTAINMENT FOR THE LADIES

Wednesday, the first full day of the meeting, was strictly a business day, with sessions morning, afternoon and evening. All-day entertainment, therefore, was provided for the ladies under the guidance of the Woman's Committee, of which Mrs. R. Sanford Riley was chairman, assisted by the wives of the Worcester membership. At ten o'clock in the morning automobiles left the Bancroft Hotel bearing the ladies to an interesting exhibit at the Crompton and Knowles Loom Works, where fancy looms were in operation. This was followed by a motor ride around Lake Quinsigamond and to Shrewsbury for a call at Iristhorpe, the summer home of Major and Mrs.

MAIN STREET AND CITY HALL, CHARACTERISTIC OF WORCESTER'S BUSINESS SECTION

Homer Gage, where the visitors were afforded the opportunity to see the magnificent gardens and landscape architecture of the estate.

The plant of the Worcester Corset Company was the next stopping place. This is one of the model factories, not only of Worcester, but of the country. Although its main buildings were erected several years ago, its features, with respect to cleanliness, ventilation and general hygienic and attractive surroundings, are comparable to the best that is to be found anywhere. The guests were received by Mr. E. Seward, treasurer of the company, and lunch was served in the main dining room. Each table was decorated by flags of the allied nations, with a carnation at each cover. After lunch the guests inspected the factory and the specially arranged exhibit of the company's products.

The next event was the trip to the Tatnuck Country Club, where tea was served and the guests spent an hour in enjoyment of the club honse and grounds. The interior was beautifully decorated by bouquets of rare flowers contributed by Mrs. Charles H. Morgan, wife of the late Charles H. Morgan, former president of the Society.

In the evening, during the professional session, a bridge party was arranged at the Bancroft in which many of the ladies participated.

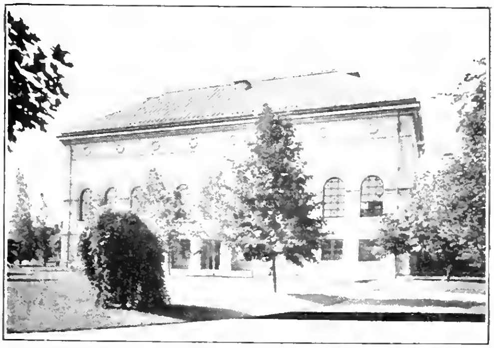
Thursday was a patriotic day, symbolized by a visit to the famous Salisbury mansion, built by Stephen Salisbury in 1770 and now used as headquarters for the Red Cross. At noon the party was taken to the plants of the Norton Companies to join with the engineers at luncheon and in the inspection of the interesting featnres of the Norton Companies' plants.

The ladies who attended the Worcester meeting were most appreciative of the reception which they had received and the care and thonght which had been displayed by the wives of the Worcester members in making their stay at Worcester so enjoyable.

The Automobile Trip on Friday

Members were warned to be on hand early on Friday morning to secure their assignment to cars for the all-day trip to Camp Devens, Lexington, Concord and the Wayside Inn. The guests were there and started on time, but shortly after it began to rain, and at times during the forenoon there was a

Norton Company's Administration Building, where Session was held on Friday Afternoon



Art Museum where Reception was held on Tuesday Evening

downpour which resulted in some delay and difficulty in getting about when Camp Devens was reached.

The visitors were to witness an artillery exhibit, and about twenty cars reached the artillery grounds, but *fortunately*, rather than unfortunately, the others did not reach this point, for, owing to the muddy condition of the road leading to the field, it would have been difficult not only to have made the trip, but to arrange for the parking of the cars. Toward noon the showers abated while the company waited for lunch, and in the afternoon the skies cleared and the balance of the trip was made under ideal weather conditions.

Camp Devens was a revelation to many of the party, who realized what equipment was required for water supply, sewerage, heat, etc., in addition to the visible buildings.

Luncheon was served promptly at the appointed time in one of the dining halls, each person bearing his tray and being served in a manner akin to what might be devised by an expert scientific manager—an example that might well be studied by many who have attempted to conduct similar functions on a much smaller scale.

After continuing through Concord and Lexington most of the party returned by the way of the Wayside Inn, where tea was served and another delightful hour was spent in the inspection of this quaint and historic hostelry.

General and Local Committees

The professional sessions, as usual, were in charge of the Committee on Meetings of the Society, L. P. Alford, chairman. The chairmen of the local committees having the general direction of the convention were as follows:

General Committee, George I. Rockwood (Paul B. Morgan; vice-chairman, Howard P. Fairfield, secretary, William W. Bird, treasurer); *Reception*, John W. Higgins; *Women's Committee*, Mrs. R. Sanford Riley; *Hotel*, R. C. Cleveland; *Transportation*, James F. Healey (John P. Coghlin, vice-chairman); *Automobile*, John C. Harvey; *Finance*, William W. Bird; *Entertainment*, George N. Jeppson; *Printing and Publicity*, Howard W. Dunbar; *Chamber of Commerce*, Charles E. Hildreth.

Various sub-committees and individuals comprising the membership of the above committees were directly in charge of the several events of the meeting; and in fact the whole Worcester membership and their wives, and many other of the local people personally helped to make the meeting the great success that it was. Everyone in attendance was enthusiastic in his praise and pronounced the gathering one long to be remembered.

OPENING SESSION

ON Tuesday evening the first gathering was held in the ballroom of Hotel Bancroft and constituted a reception to the visitors by the Worcester Chamber of Commerce, of which R. Sanford Riley, Mem.Am.Soc.M.E., is president. Mr. Riley greeted all present in behalf of the men of Worcester who make up the membership of the Chamber, saying in part:

"You will find our city interesting in many ways. First of all on account of its geographical situation. It is called a one-street town, because the main street runs along a valley with comparatively little level space at either side for cross streets. Our 200,000 population is strung out over a length of nearly nine miles. But the part of Worcester that is the most significant to engineers is the section parallel with Main Street where the industrial buildings stand. Mr. Washburn will speak later about the influence these early manufacturing buildings had in bringing to Worcester the infant industries which have now made the city famous.

"The ladies have even had to come to Worcester for such fundamental equipment as is required in the kitchen, for what kitchen is complete without some wire-goods device made from Worcester drawn wire. Machine shops all over the country send to us for their lathes, drills, grinding machines, planers and shapers. When one writes a letter he mails it in a Worcester-made envelope. Certainly the clothes one wears could not be woven without some of Worcester's looms. Shafting is driven by Worcester belts and trucks by Worcester chains. People travel in Worcester-built cars, both railroad and trolley. Every one has come in intimate contact with grinding wheels from Worcester because even if he does not require them for giant rolls or machine-shop work his dentist forces them on to you and into you where you feel them most. Our houses have Worcester rugs and carpets."

Mr. Riley referred to the splendid enthusiasm which Worcester had displayed in its campaigns for activities connected with the war and said this combination of coöperation and determination was its greatest asset. He hoped that the visitors would catch something of this spirit of Worcester. They had a very hearty welcome and a most cordial greeting from their friends of the city.

The chairman then introduced Mayor Pehr G. Holmes, who gave every one present assurance of the pleasure which the citizens of Worcester felt in welcoming a body such as that represented by the mechanical engineers who were in attendance.

President Charles T. Main, responding, presented the thanks of the Society to Worcester for its invitation to hold its convention in the city and for the hearty way in which the Society was received. He knew that the visiting members were in good hands with Dr. Ira N. Hollis, their past-president, as chairman of the Worcester Public Safety Committee.

Hon. Charles G. Washburn, president of the Worcester Polytechnic Institute Corporation and ex-congressman, gave an address on the Growth of an Industrial City, a report of which is here given. Following the address the members and guests were conveyed by automobile to the Worcester Art Museum, where a reception was held and an opportunity was given to view the remarkably fine collection of paintings, statuary and art objects. In close proximity to the Art Museum is the Worcester Woman's Club House, where, in Tuckerman Hall, beautifully decorated for the occasion, was held a dance.

THE DEVELOPMENT OF AN INDUSTRIAL CITY

By HON. CHARLES G. WASHBURN, WORCESTER, MASS.

I OWE it rather to the too favorable opinion of some of my friends in this Society than to any power of my own to either interest or instruct that I have the honor to address this distinguished audience this evening.

The Development of an Industrial City is the theme of my discourse; and, as this meeting is held in Worcester, it is very natural that I should confine myself to the development of industrial Worcester, typical, perhaps, of all New England communities of like character, excepting that no one industry has exclusively absorbed its energies.

The first record of any mill in Worcester is that of Capt. John Wing who had a saw and grist mill on Mill Brook, near Lincoln Square, in 1685.

The first manufactured product in Worcester was potash, made quite extensively in 1760. This gave the colonies an article of export with which to pay for manufactures imported from Great Britain. Isaiah Thomas manufactured paper here in 1785.

There was an increase in the variety of manufactures in Massachusetts early in the nineteenth century because of the embargo declared in December, 1807, and to the complications then existing between this country and France and England which led to an almost complete stoppage of importations, and manufactories of cotton goods, woolen goods, iron, glass, pottery and other articles rapidly sprang into existence. Some idea of the advancement of the world at this time from the engineering standpoint may be gained from the fact that the Academy of Science in France when consulted by Napoleon at the beginning of the century as to the steamboat spoke of it as a "mad idea, a gross error, an absurdity." When Fulton's first steamboat made the trip from New York to Albany in 1807, it happened to be the 17th of August, which caused many preachers to curse the machine on the ground that seventeen was the total of the horns and the seven heads of the beast of the Apocalypse.

Manufacturing Advantages

In 1823 attention was called to the advantages possessed by Worcester which should make it a large manufacturing center. Encouragement was found in the fact that towns in the interior of England, with no great local advantages, contained from 10,000 to 15,000 inhabitants, and that since the introduction of steam power, a population of from 80,000 to 100,000 had been reached. It was stated that Worcester would soon be at the head of canal navigation, and, in addition, her "inexhaustible store of anthracite coal, well calculated for steam engines," was referred to as being of the greatest value. There were deposits of coal here and a company was organized in 1829 to work them, but it was found to be too impure for economical use.

Peat, too, was found in the meadows about Worcester, and

in 1856 it was used to some extent as a substitute for wood and coal.

In June, 1827, Worcester is spoken of as containing "the largest paper mills, belonging to Elijah Burbank, five machine shops, at which great quantities of machinery of various kinds are made; one small cotton factory, a lead aqueduct factory and other works of minor note."

Use of Water Power

Worcester, unlike many other manufacturing cities of New England, has always been without any great water power. Commenting upon this fact, a citizen of Worcester said some time before 1835, to Samuel Slater, who had mills in the adjoining town of Webster: "We shall never be a manufacturing town in Worcester because we have so little water power." Mr. Slater said in reply: "You may live to see the time when Worcester will need all the water of Mill Brook to provide the steam for her steam engines." While it is true that we have no great water power here, it is interesting, and I think to most people a rather surprising fact, that the small streams tributary to the Blackstone River have played a most important part in making possible manufacturing enterprises which have subsequently developed to a considerable size.

If I were asked to give the reasons for Worcester's growth in manufactures, I should mention as one of them the unusual opportunities offered to mechanics to begin business in a small way without incurring the risk incident upon the erection and equipment of a shop. Had this not been the case, many individual companies and corporations doing today a large business could never have started.

Many incidents might be given of individuals who have begun with one machine, gradually increasing their business until it has reached a considerable magnitude. Growth of this kind is likely to be permanent. It would be almost literally true to say that there is no large manufacturing business long established in Worcester that has not at some time in its history occupied one or another of the buildings erected for rent with power to a number of tenants. There are some exceptions, but they are few.

Another very important condition has been that of abundant transportation facilities, beginning in 1828, with the Blackstone canal, connecting Worcester and Providence, and followed by the railroads connecting Worcester with Boston in 1831, with Springfield in 1839, with Norwich in 1840, with Providence in 1847, with Nashua in 1848. It will thus be seen that from an early date Worcester had the advantage of the best railroad facilities existing at the time, which, with the introduction of steam power, made certain her rapid growth as a manufacturing city. Thirty years ago there was not only direct communication with all points north and south, but there were five outlets and thirteen different lines, more or less, affording direct communication with the West.

Of course, manufacturing here, as elsewhere, was dependent almost exclusively upon water or horse power until 1840. William A. Wheeler is said to have had a steam engine of some sort to run a fan in his foundry, but in 1831 or 1832 he abandoned this engine and substituted horse power, which he used until 1840, when he put in another engine. He is credited with having the first steam engine employed in the state west of Boston.

Industrial Growth

It will obviously be impossible to treat in any detail the development of all of the manufacturing plants in Worcester. The story of each of them is full of romantic interest. I must content myself, however, with dealing with a few of them, typical, perhaps, of all. It is always interesting to know why a business is located where we happen to find it, and there is usually a good reason.

Among the most important industries in Worcester is the manufacture of machine tools. The founder of this industry here was named Samuel Flagg, or, as he was more familiarly known, "Uncle Sammy Flagg." He had a machine shop in West Boylston, a neighboring town, and moved to Worcester

Hon. Charles G. Washburn

in 1839 in order that he might save the cartage of his castings to his machine shop in West Boylston, where he built tools and cotton machinery from patterns made by William A. Wheeler.

Mr. Flagg hired room and power in what was then known as Court Mills, built on that triangle of land bounded by Main, Union and Old Market Streets, and adjacent to Lincoln Square. He had no planer when he commenced; the work was done by hand chipping and filing. Court Mills was the cradle of the machine-tool industry in Worcester, and Mr. Flagg rocked the cradle. To his men and apprentices and to those who, in turn, served them, can be traced almost all of the concerns now engaged in this business.

Manufacture of Looms

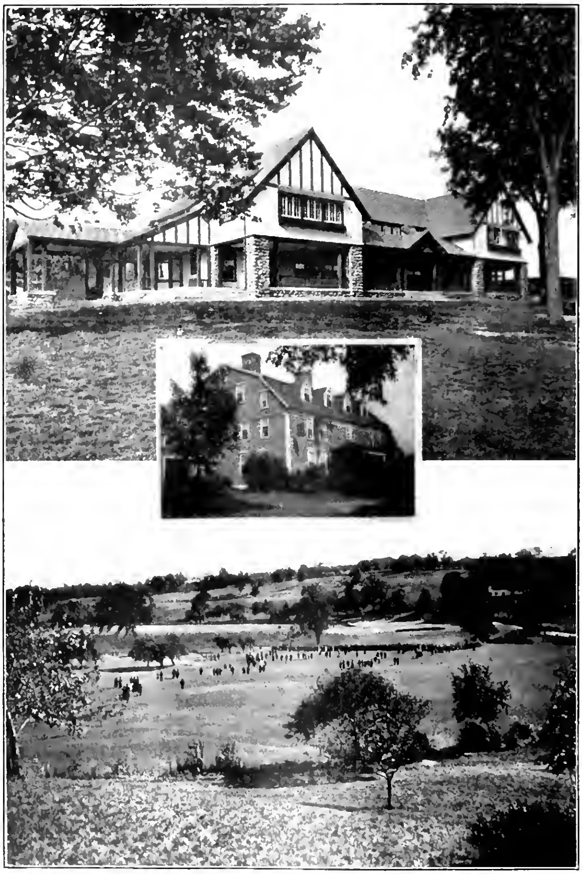
The manufacture of looms has for many years occupied a prominent place in Worcester, and it owes its location here to a very trivial circumstance. In 1836 William Crompton, then thirty years old, a native of Lancashire, England, came to Taunton, Mass., and went from there to Lowell at the request of the Middlesex Mills, where he applied his patented fancy harness motion, and, for the first time, wove fancy woolens by power. The late Samuel Davis soon after this happened to meet Mr. Crompton at a hotel in Boston. Mr. Crompton told him that he wanted to find someone to build his looms and expected to make a contract at Lowell. Mr. Davis suggested that Worcester would be a good place to build the looms. Mr. Crompton came here and made an arrangement with Messrs. Phelps and Bickford to build looms upon royalty. It was

in this way that the seed of the loom business was planted in Worcester.

In 1847 the late L. J. Knowles commenced the manufacture of cotton warp at Spencer, and subsequently was engaged in the manufacture of satinets in Warren. He made some improvement on the looms he was then running, and operated the germ of the mechanism of the fancy looms which were later built by his company, which moved to Worcester in 1866. In 1897 these two industries were consolidated under the names of Crompton and Knowles Loom Works with which the name of Worcester is associated the world over.

Perhaps I may be permitted to diverge at this point to consider for a moment the genealogy of business. Every manufacturing enterprise, like individuals, has ancestors and often descendants, although we know of some that have been childless. It is a very natural thing that the late George Crompton, a manufacturer of looms, should have become interested in developing a loom for weaving Brussels carpets by power. This led to the organization of The Crompton Carpet Company, of which M. J. Whittall was the superintendent. This association led to the subsequent absorption of the business by Mr. Whittall.

But this is not all; one of George Crompton's associates, and a man of great inventive capacity was Horace Wyman. His son, H. Winfield Wyman, and Wyman F. Gordon, a son of another of Mr. Crompton's associates, began in 1883 the manufacture of forgings for parts of looms, such as crankshafts, shuttle-box binders, and other forgings used in the manufacture of this class of machinery. That business has developed into the Wyman Gordon Company, whose products are now known in every part of the country. It may truthfully be said that if Samuel Davis had not accidentally met William Crompton in Boston in 1840, the loom industry, carpet industry, and the Wyman-Gorden drop-forgings plant might never have existed here and the manufacturing aspect of the city would have been far different than at present.



WORCESTER COUNTRY CLUB, THE SCENE OF THURSDAY'S GARDEN PARTY. THE WAYSIDE INN IN THE CENTER, VISITED DURING THE AUTOMOBILE TRIP ON FRIDAY

THE WIRE BUSINESS

Perhaps Worcester is as closely associated with the development of the wire business as with any other. This was begun in Worcester in August, 1831, by Ichabod Washburn and Benjamin Goddard, on a small water privilege on what was known as Mill Brook, where they manufactured wire and wood screws. There is an interesting incident connected with the early history of the business which illustrates the great importance of comparatively tritlng circumstances.

It seems that some time during the year 1831, Mr. Washburn, Mr. Goddard and General Heard visited North Providence, where three brothers by the name of Read were making wood screws. An arrangement was made with them and they moved their screw machinery to Worcester on a canal boat. The journey occupied three days. The business was conducted here under the patronage of Washburn and Goddard, at the Northville wire mill. At some time between April, 1836, and March, 1837, the screw business was moved back to Providence on a canal boat and ultimately became the nucleus of the Eagle, now the American Screw Company. Had the differences been adjusted — and they were probably trifling—the business of the American Screw Company might have been developed in Worcester rather than in Providence.

Washburn and Goddard also made card wire; indeed, the demand for card wire was probably the reason why the business started in this vicinity. The manufacture of cards was a very ancient industry. Tacks were first used in making hand cards, and the industry in the neighboring town of Leicester dates back to 1785. The card wire had been imported from England. From a report of Albert Gallatin, then Secretary of the Treasury, made in 1810, it appeared that the demand for cards was twice as much in 1809 as in 1808, and was increasing. Then this statement was made: "The wire is imported, and serious inconvenience would attend the stoppage of the supply, although the manufacture might and would be

immediately established to supply all demands if the same duty were laid on wire, now free, as on other articles of the same material."

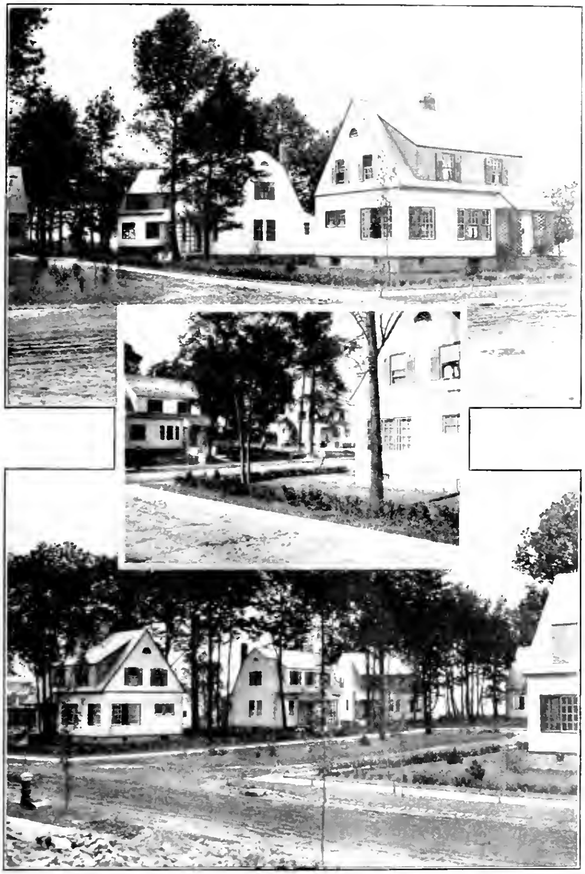
In 1835 Ichabod Washburn moved to the fourth privilege on Mill Brook, the present location of the North Works of the American Steel and Wire Company. From 1837 until 1847 he purchased in Sweden his wire-rod billets. These were rolled into wire rods at Fall River, Troy and Windsor Locks, Conn., which were brought to Worcester to be drawn into wire. The inconvenience of having rolling done at a distance led Ichabod and his brother Charles, in 1847, to locate a rolling mill at Quinsigamond, the eighth privilege on Mill Brook, now the South Works of the American Steel and Wire Company.

The manufacture of music wire in 1850; the introduction of continuous tempering in 1856; the manufacture of crinoline wire in 1859; the introduction of continuous cleaning and galvanizing in 1860; the use of the continuous rolling mill in 1869, mark the conspicuous products and processes up to 1870.

The introduction of bessemer steel about 1876 created, as is well known, a revolution in the wire business, and furnished a better and cheaper material for many purposes, among them, and in the wire business chief among them, for the manufacture of barbed wire.

Factor in City's Growth

In the spring of 1876, upon the urgent advice of Charles F. Washburn, an officer of the company, who believed that the introduction of barbed wire would solve the fencing problem for the farmers of the West, the Washburn-Moen Manufacturing Company caused automatic machinery to be constructed and patented, and in conjunction with Isaac L. Ellwood of DeKalb, Ill., acquired control of the underlying barbed-wire patents. The amount of barbed wire manufactured in the country increased from five tons in 1874 to about 150,000 tons in 1888. Its effect upon the business of the Washburn and Moen Company may be measured by an increase in the number of operatives from 700 in 1875 to 2100 in 1889.



Views in the Indian Hill Community of Employees' Model Homes, Developed by the Norton Company—A Point of Attraction for the Visitors on Thursday

Among the first experiments with the telephone were those at the Washburn and Moen Works. A memorandum found among the papers of the late Charles F. Washburn states that the first experiments in talking through a telephone wire on the premises of the Washburn and Moen Manufacturing Company were in the month of March, 1876, with No. 20 bright iron wire laid on the floors of all the rooms in the lower story, from the rolling mills into the office of Charles H. Morgan, superintendent, at 94 Grove Street. The Washburn and Moen Company were large manufacturers of bale ties for binding hay, of copper wire, of wire rope, wire nails, and of insulated wire and cables, all of which greatly contributed to the growth of the business, and of the community. This business was acquired by the American Steel and Wire Company in 1899, which became one of the constituent companies of the United States Steel Corporation in 1901.

The Worcester Wire Company, the Spencer Wire Company, the Wright Wire Company, and several wire-working plants, have all greatly stimulated Worcester's growth.

It was natural that Charles H. Morgan, Past-President, Am.Soc.M.E., who, while general superintendent of the Washburn and Moen Manufacturing Company, had devoted much time to the construction of mills for rolling wire rods, should have continued in that field after he left the service of the corporation. He organized the Morgan Construction Company in 1891, to build metal-working machinery.

Wire rods have always been rolled in this country upon two distinct types of mills, the "Garrett Mill" and the "Morgan Continuous Mill." The latter has gradually displaced the former. The first continuous mill in this country was the one I have referred to, built in the fall of 1869 by the Washburn and Moen Company, and, in its essential features, an English invention. These continuous mills now produce an average of 400 tons a day of No. 5 wire rods.

By way of comparison, it may be interesting to state that in 1853 the capacity of the rolling mill at Quinsigamond was six

Camp Devens, Near Ayer, Mass., Visited by the Members and Their Guests on Friday of the Spring Meeting. This Visit New England Cantonment Was an Exhibition of Engineering and Contracting Skill, Constructed as it was in Ten

long tons a day of 10 hours. The automatic reels known as the laying and pouring type, now in universal use throughout the world and absolutely essential to a large tonnage, were invented by Charles H. Morgan and Fred H. Daniels, while they were with the Washburn and Moen Company.

Other Great Industries

Worcester has taken a foremost place in the development of the manufacture of machine-made envelopes. The third United States patent on a machine for making envelopes was issued to Dr. Russell L. Hawes of this city in 1853. This was the first successful machine in the country. Arnold, Rheutan, and the Messrs. Swift, made their contributions to the development of envelope-producing machinery. The three largest plants here were absorbed in the United States Envelope Company in 1898. Besides these, several independent plants are in operation, all contributing to give Worcester a conspicuous place in this industry.

In 1875, F. B. Norton had a pottery in a small wooden building on Water Street, where, in 1879, he began the manufacture of grinding wheels by the vitrified process. Since that time the production of these wheels has far outstripped that of any other kind and grinding has taken a large and revolutionizing place in many lines of manufacture.

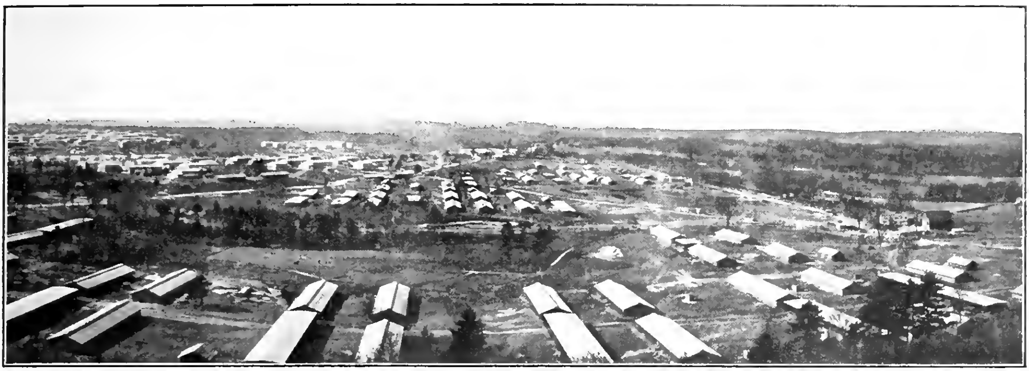
The Norton Emery Wheel Company was incorporated in 1885. Two of the prime movers in the development of this business were Milton P. Higgins, then superintendent of the Washburn shops of the Polytechnic Institute, and George I. Alden, then professor of mechanical engineering. Both of them have been vice-presidents of this Society. In 1886 the Norton Company erected new works at the present location at Barbers Crossing. Of the marvelous development of the business of this company I need say nothing. You have seen the plant. But if you would keep pace with the growth, you must see it every day.

When I last inquired in March, 1917, they had over 3500 employees engaged in the manufacture of grinding wheels and other abrasive products and 850 engaged in the manufacture of grinding machines. But the story is not yet told. This company has been among the pioneers in establishing free medical service and a system of medical supervision of its employees, has provided homes for them in what is now a most extensive and attractive community, has supplied them with garden plots, has an agricultural society and an annual fair.

This company not only makes a tremendous contribution to the material prosperity of Worcester, but to its fame as well. Mr. Higgins was a strong believer in giving students in mechanical engineering part of their training in a commercial shop. He had administered this system when he was superintendent of the Washburn shops of our Polytechnic Institute. He became a strong advocate of this half-time school and read a paper on this subject before the Society in 1899. Mr. Higgins subsequently was instrumental in securing legislation which provided that any city or town might establish an independent industrial school, the state and city or town to share equally in the cost of maintenance. He later became chairman of the first board of trustees of the Worcester Trade School.

I must resist the temptation to speak in any detail of the numerous industries not already mentioned that have contributed much to Worcester's growth and prosperity, of the manufacture of textile machinery, of the manufacture of card clothing begun here over seventy-five years ago, a business with which the name of Earle was associated for over one hundred years; of the manufacture of wool spinning machinery, once a prosperous but now a decadent industry because of the tremendous growth of the manufacture of worsteds; of the manufacture of thread, and of twisting machinery; of the foundries; of agricultural implements and machinery; of wrenches with which the name of Coes has been associated since 1840; of the building of cars, begun here in 1833 by Osgood Bradley, now under the management of the third generation of that surname; of the numerous manufacturers of woodworking machinery; of firearms, the manufacture of which by Ethan Allen was begun seventy years ago; of the Worcester Machine Screw Company, now one of the constituent companies of the Standard Screw Company; of the manufacture of steam engines, more extensive formerly than now; of the manufacture of boots and shoes, and of the manufacture of leather belting—one of Worcester's great industries.

Referring again to the genealogy of business, Isaac Goddard came to Worcester in 1812 and was apprenticed to Elijah Burbank at Quinsigamond to learn paper making. What more natural than that he should later begin to make paper machinery. The firm of Howe and Goddard became Goddard, Rice and Company, which, in turn, became Rice, Barton and Fales, the firm name for over forty years, and now in the management of the third generation of the Barton family. The J. R. Torry Razor Company, incorporated thirty-eight



Sanborn Photo Co.

Was Made Through the Courtesy of Secretary of War Baker and Major General H. F. Hodges. The Building of This Weeks, and Consisting of 1500 Buildings Covering 10,000 Acres and Having a Housing Capacity for 43,000 Soldiers

years ago, was the first to successfully manufacture razors in the United States.

The Worcester Corset Company, to be visited by some of our guests during this convention, is a monument to the sagacity of D. H. Fanning. Sixty-one years ago the late Samuel Winslow ventured to make twenty-five pairs of skates, and in the first year sold nineteen pairs. The business still continues on a somewhat larger scale under the administration of his son.

The plunger elevator was designed nearly fifty years ago by Charles H. Morgan and Milton P. Higgins, and is still made here. The manufacture of cartridge belts, begun in 1880, has vastly increased because of present war conditions. The Worcester Pressed Steel Company, the Morgan Spring Company, the Heald Machine Company and the Allen-Higgins Wall Paper Company are all a part of Worcester's new industrial center—Barbers Crossing, created by the Norton Company.

In the short space of twelve years the Rockwood Sprinkler Company, product of the inventive genius of your associate, George I. Rockwood, Mem.Am.Soc.M.E., has sprung into national prominence as designer and installer of fire-sprinkler systems.

Such, my friends, is the brief story of the causes of Worcester's industrial growth, not unlike, I fancy, the growth of other industrial cities in New England. There is nothing spectacular about it. Indeed, judged by the standard of the modern industrial community created by the hand of the engineer almost over night, the development seems slow, covering, as it does, a period of eighty years, more or less, but if it has been slow, it has been sure, and the roots strike down deep. Most of those who laid the foundations were men of simple character who began life in a small way and made slow progress. They were reticent, modest, industrious, shrewd, enterprising and some of them very public spirited. They accumulated their property not always because of great gains, but more often because of frugal living and large savings.

BUSINESS MEETING

Amendments to the Constitution Adopted and Another Amendment Proposed; Five Committee Reports Presented; Address by Prof. O. Steels of Belgium; Tributes to Prof. Hutton

On Wednesday morning, the members were taken by special cars from the Hotel Bancroft to the gymnasium of the Worcester Polytechnic Institute, where the Business Meeting and the first Professional Session were held.

President Main presided and in opening the meeting called for the result of the ballot by the membership on the amendments to the Constitution, which were first announced to the Society at the Spring Meeting of 1917 and were published in The Journal for October, 1917. The vote was as given below, and the President declared the amendments adopted.

Amendments	*Yes*	*No*
C 26	1110	20
45	1113	17
47	1116	14
55	1121	9
56	1124	6
58	1128	2

Next in order was the presentation and discussion of reports by special committees. Three of these were brief reports, presented by title, one by the Sub-Committee on Fire Protection, John R. Freeman, Chairman, on new tests of materials for fire prevention; one by the Committee on Steel Roller Chains, Prof. C. H. Benjamin, Chairman, constituting a progress report of this Committee; and a report by the Committee on Flanges and Pipe Fittings, of which the late John P. Sparrow was Chairman, constituting an addition to the 1914 American Standard for pipe fittings. This supplementary report covers heavy pressures up to 3000 lb. per sq. in.

Report on Screw-Thread Tolerances

The next report was that of the Committee on Limits and Tolerances in Screw Thread Fits, Luther D. Burlingame Chairman, which is the result of several years' work of this Committee, during which not only was an extended investigation made of the subject, but a large number of taps and screws were measured, both for diameter and lead, and the

results tabulated to determine the present practice. A large number of gages were also distributed among manufacturers, which were tried out in their regular work to determine what could be considered commercial practice.

In presenting the report, Mr. Burlingame said that the proposition was such as might present itself to the individual who purchases taps in one part of the world, bolts and screws in another and nuts in another, from different manufacturers and at different times; and who desired to produce interchangeable work commercially, in distinction from precision work.

In taking up the matter, the Committee endeavored to weigh all the phases of the situation and naturally found many viewpoints, so that the report as finally worked out was in the nature of a compromise. The attempt had been made to put it in such a form that it could be used in the every-day shop in a practical way. The Committee had voted to present the matter as a tentative report in order to bring about discussion and to enable further steps to be taken, if necessary, to better adapt it to the purposes for which it was prepared. Since that time, a measure had been introduced into Congress and passed by the House (the Tilson Bill), calling for a commission to take up the whole matter of limits and tolerances of screw threads with the idea of having the authority and sanction of the Government back of whatever might be adopted. It was to be hoped that this bill would become a law.

After a general discussion, an adjournment by those interested was made to another room so that more time could be given to the subject than could be allowed during the regular business session. Since this discussion was primarily for the benefit of the Committee in its future consideration of the report, it is of interest only to a limited extent to the membership at large. It will be the purpose of The Journal, however, to touch upon its salient features when the report is later published in its pages.

Report of Committee on Weights and Measures

The last report to be presented was that of the Committee on Weights and Measures, of which Mr. Burlingame is also Chairman. It comprises an abstract of a report entitled the Metric System in Export Trade, by F. A. Halsey, of this Committee, based upon more than 1400 answers to a questionnaire sent to several thousand manufacturing firms in the United States. It was considered by the Committee that the resulting information was of such interest and value that the Society would be rendering real service if the essential facts, as deduced from the replies, were presented to the membership.

Samuel S. Dale, of Boston, opened the discussion by reporting the results of investigations made in South America by means of questionnaires issued by the Institute of Weights and Measures. He said these investigations show "that the metric system has caused confusion in South America instead of promoting uniformity. The people of Latin America, both Portuguese and Spanish, had a very good system which they are still using. The metric system, however, has been made compulsory by law, and to a certain extent they are using both systems; and in proportion to the extent to which they are using the metric system, the confusion has increased."

C. A. Briggs, of the Bureau of Standards, said that the subject should have a fairer discussion than appeared to be the case in the report, and he considered it unfortunate that it had come up at this time when the country was devoting its energies to the war. He declared that both the report and Mr. Halsey, its author, were biased and he was critical also of the American Institute of Weights and Measures which, while there was a great deal to do in relation to the subject of weights and measures, had devoted its energies to opposing the metric system.

He contended that the report was of value only if it were considered that foreign trade relations were satisfactory at the present time, but that the Government's interest in the matter was to increase export trade and our foreign trade relations. The question was how best to do this.

William Kent said he had heard the metric system discussed for 40 years and had noticed the unwillingness of advocates of the system to read the facts. In consequence, when metric advocates received a pamphlet like this from Mr. Halsey, it would go into the waste basket. They do not want anything of that kind. The thing to do is to try to get this report to the people who *will* read it. Here are hundreds of statements of facts and what is wanted are the facts.

L. P. Alford was in sympathy with Mr. Briggs in deprecating the expenditure of energy at the present time in the discussion of the metric system, when our efforts should all be in the direction of winning the war. He desired to point out, however, that the initiative which resulted in this report, was the report made in 1916 on the metric system in export trade, by the Bureau of Standards. In other words, this assemblage of facts is a reply to the previous report.

F. A. Halsey, in referring to the statement that the only activities of the Institute of Weights and Measures had been to combat the metric system, said he fully agreed that it was an unfortunate time to bring up the subject, but that they were defending themselves. They had a constructive program and had a great deal of work of a constructive character to do; but they had had no chance to take it up because they had to oppose the movement for the metric system.

With regard to the report of this Committee and the suggestion that it was biased, he said it was a statement of facts by others. He invited anyone to read the questionnaire as printed, and to judge for himself as to whether the questions were fair.

Proposed Amendment to the Constitution

On the initiative of the Council, Jesse M. Smith, Chairman of the Committee on Constitution and By-Laws, proposed an amendment to the Constitution to take the power of appointing the regular Nominating Committee out of the hands of the President and transfer it to the voting membership. The President stated that this proposed amendment was the most important that had come up for the Society in recent years. The proposed amendment was as follows:

"Strike out line 3 of C-47 which reads 'A Nominating Committee appointed by the President,' and insert the words 'Committees of' before 'Tellers' in line 4."

"Amend C 48 to read as follows:

"There shall be a Nominating Committee whose duty shall be to select candidates for the elective offices to be filled at each election. This Committee shall be elected annually by the voting membership of the Society. Other nominating committees having the same powers, may be constituted by the voting membership. The number of members, the election, organization and procedure of all Nominating Committees shall be as the By-Laws shall provide."

In proposing the amendment, Mr. Smith said that it embodied the fundamental principles and that the details of carrying out the election in any manner would be embodied in the By-Laws to be prepared later.

George I. Rockwood asked how the candidates were to be nominated, a question which led to a general discussion which was concluded by Louis C. Marburg of the Sections Committee, who confirmed what Mr. Smith had said and stated that the matter had been discussed by that Committee and a somewhat elaborate scheme worked out for a large Nominating Committee comprising delegates from the different Sections. The matter was brought before the Council and finally the point was raised that the Constitution should contain only fundamental ideas and that the details of appointing or selecting the Nominating Committee should be left to the By-Laws, which, however, could not become workable until the constitutional change was made.

Discussion Desired by Membership

On motion of Prof. Arthur M. Greene, Jr., the meeting voted to request a general discussion by the membership on the proposed amendment, with a view to publishing comments, and particularly adverse comments, if there are such. Communications on this subject are, therefore, solicited.

Engineering Council

Alfred D. Flinn, Secretary of the Engineering Council, was in attendance and gave a brief review of the organization of the Council and of the work which has developed under its direction during the past few months. The organization of the Council has already been fully presented to the readers of The Journal and the following summary of its committees will be of added interest:

Besides the usual standing committees is the American Engineering Service Committee, engaged in finding specialists for Government service, one of the recent requests being for men for submarine service and in response to which Mr. Flinn appealed to those in attendance at the meeting to send the Engineering Council the names of any graduates of technical schools under 35 years of age who might be ambitious for submarine service; the committee on Fuel Conservation is in coöperation with the Bureau of Mines and the U. S. Fuel Administrator; a recently established committee on Water Conservation through one of its members, Calvert Townley, recently presented a most valuable paper on the subject to the U. S. Chamber of Commerce; also, a committee on Industrial Affairs, which has been engaged in combating with other large organizations the so-called "anti-efficiency rider" in appropriation bills before Congress. Recently, the naval appropriation bill as finally passed indicated at least partial victory for the position which engineers are taking in permitting bonuses and similar rewards for additional or better work accomplished in the processes of production.

Arthur M. Greene, Jr., said that the Council of the Society at its meeting in Philadelphia recently, went on record as approving the action of the Engineering Council and believed it was its intention to have notification to this effect sent to Washington. He therefore introduced the following resolutions which were approved unanimously by the meeting:

"Whereas, It has come to the attention of the Spring Meeting of The American Society of Mechanical Engineers that the Engineering Council has sent a communication to Washington protesting against the riders to the appropriation bills preventing the use of money for work where time studies are made and where bonus is to be paid for work, and that this protest has been approved by the Council of The American Society of Mechanical Engineers; and

"Whereas, It is the opinion of this Society that accuracy and speed of production are important factors for the successful prosecution of the war, and, as engineers, we think time studies and bonus systems will aid in the increase of production and accuracy;

"Be It Resolved, The membership of this Society at its semi-annual meeting held in Worcester, Massachusetts, June 5, 1918, approve of the resolutions of the Engineering Council and respectfully request the President of the United States and both Houses of Congress to give careful consideration to the disastrous effects of these riders to the proper amount of production of material for our men at the front."

The resolutions were immediately wired to President Wilson, to the President *pro tem.* of the Senate, and to the Speaker of the House, and have since been acknowledged.

Telegrams were read, one from Col. John J. Carty of the Signal Corps and one from John D. Ryan, Chief of the Aircraft Production Board, asking for names of engineers to enter the service, one for a man to undertake the management of a large Signal Corps shop and the other for men who could in any way assist in aircraft production. These are indicative of the many calls which are coming to the Society for specialists in different fields which, to a large extent, have been successfully taken care of by its employment department.

Remarks by Prof. O. Steels

Prof. O. Steels, of the University of Ghent and the head of the Belgian Mission on Industrial Management, then gave a brief address, expressing his appreciation of the Society's assistance to the Mission. The industrial energy of Belgium is still great even in the face of the destruction of most of its sources, and will need the special impetus of scientific organization and management. This Mission represents the Belgian Government's study and preparation of steps toward starting industry after the war.

Some idea of the magnitude of the task of reconstruction to which the Mission looks forward was obtained from Professor Steels' brief review of the country's activities.

Only 30 per cent of the population (7,500,000 in 1910) was engaged in agriculture but the culture was so intensive that the yield was $2,000,000 per year. Horse breeding was one of the best-known activities, resulting in an annual export of 1400 horses a year to the United States. Horticulture was also important, amounting to an export trade of $500,000 worth of products to this country each year.

Besides those principal enterprises, Belgium is rich in some of the natural resources. The coal mines are deep and were operated to yield about 23,500,000 tons a year. A new and important coal region was discovered a few years ago and steps had been taken toward working it. It is presumed that many of those pits are now operated under German rule.

In 1911, twenty-five steel works, employing 18,000 workmen, produced 2,200,000 tons of iron and steel and 1,650,000 tons of finished steel products were turned out by the rolling mills. The earliest developments of the steel industry were first perfected in Liège and its vicinity. Near Liège, too, the zinc industry was a flourishing one, producing about one-quarter of the world's output of that commodity. Machine shops, locomotive works and similar industries were well developed.

Flanders was especially given over to the textile industry where there were about 1,200,000 spindles at work. Some wool and jute were also produced in that region. The glass industry—both ordinary and plate glass—was world-known. In harbor facilities, Antwerp was one of the first commercial ports of Europe, renowned for its world trade.

In closing, Professor Steels spoke feelingly of the military achievements of his country: "From the first days of August 1914 our army headed by our King has been in the field, and is still in the trenches doing its bit to stem the German onslaught. King Albert and Queen Elizabeth have lived with their soldiers during these four last years, sharing every day their dangers and their sufferings."

Tributes to the Late Frederick R. Hutton

As a fitting close to the Business Meeting, the President spoke briefly of the late Frederick R. Hutton, Honorary Secretary of the Society, who, more than any other member, had been closely associated with the activities of the Society. He said he had appointed a committee to prepare a memorial of Dr. Hutton, which would be presented at the next Annual Meeting in December.

Past-President Worcester R. Warner added a few words of appreciation, saying: "Professor Hutton is the one in the estimation of the older members who did more than any one else for the upbuilding of this Society, for making us acquainted with each other, for making the meetings pleasant for us as well as happy and agreeable in every way. When he first became our Secretary the membership was not made up of the type of men I see before me today. There were very few college men among the early membership of this Society, and that made it all the more difficult for the Secretary, who was a scholar and a master of English, to get along and endure our poor English. He used to translate my papers and my reports into English, and I believe it was an important part of his work to see that we made as creditable a record and report as possible. I used to thank him for it, which I have no doubt others of you here have done, and I told him years ago I wondered at the patience he had with us. And so we all remember him with the greatest pleasure and reverence. I mentioned to some of our members a little while ago the excellent resolution which he prepared expressing our thanks to the British Institution when they entertained us some eight years ago. I wish the members would read it;[1] it reads like Emerson or some of the other masters of English; and there were in those early days comparatively few masters of English in this Society."

William Kent also added a few words in which he referred to a remark made by Professor Hutton in reference to Mr. Holloway, one of the early Presidents of the Society, to the effect that his memory of Mr. Holloway was particularly of the treatment he received from him when a young man visiting the Lake Erie Engineering Works in Cleveland; that Holloway endeared himself to all the young men by treating them so kindly, giving them every facility to see his works and to talk with him and to have a good time with him. "That was Hutton's opinion of Holloway; that is my opinion of Hutton. Hutton did the same thing. Hutton's fond memory of Holloway was the treatment he received from Holloway. Our memory of Hutton is the treatment we received from Hutton. We know what joy it was to Hutton to have the memory of those who had been good to him; may it be an inspiration to the younger men who knew Hutton more recently to remember that that is the kind of man he was and that is the kind of men they should be—whose joy it is to help their fellow men."

NEW ENGLAND DAY SESSIONS

When the program for the Spring Meeting was arranged by the Committee on Meetings, it was planned to have the sessions on one day comprise papers contributed by engineers in Worcester and other New England cities, and this program was carried out with the following contributions relating to New England industries:

The Small Industry in a Democracy, George H. Haynes.

The Textile Industry in Relation to the War, J. E. Rousmaniere.

Converting a Factory for Munitions Manufacture, John S. Holbrook.

Some Economic Aspects of Fire Protection Problems and Hazards in War Times, J. Donald Pryor and Frank V. Sackett.

Oil Fuel in New England Power Plants, Henry W. Ballou.

This session developed naturally from that of the evening before, at which Mr. Washburn spoke on the Industries of Worcester, so many of which began in a small way. Following this was the address on Wednesday morning by Prof. George H. Haynes, treating of the relations of the small industry to a democracy; and in turn were the papers on certain of the specific industries and problems that are now being considered by New England manufacturers.

The papers by Messrs. Pryor and Sackett and by Mr. Ballou appeared in The Journal for June, and in this number are abstracts of the addresses by Professor Haynes and Messrs. Rousmaniere and Holbrook.

At the opening of the meeting, Dr. Hollis brought a message to the membership on the need for the conservation of our resources and the coal situation, which is also reported.

ADDRESS OF DR. IRA N. HOLLIS

I have one message that I want to send back to all parts of the United States, to every Section and to every engineer who can be reached through this meeting. While we are sitting here talking about things that we hope will be to the benefit of our country, our boys are quietly going to register themselves for service. While we are sitting here, too, some of our sailors are losing their lives on the sea and our army is shedding its blood on the other side. We ought to carry back home a certain consecration to duty for those boys. After all, what is it they have gone to fight for? We call it for democracy—to make the world safe for democracy; but there is something far more fundamental than democracy in this world and that is the Ten Commandments. Our boys are going to the other side to bring back to us the influence of that most appealing figure in all history, far greater than the victors of nations, far more potent than emperors and crowned kings and the glories of democracy,—the influence of Him who died on the cross.

The important problem before us, at the present time, I contend, is essentially a fuel problem. In Massachusetts, we bid fair in the course of the next year to be at least 6,000,000

[1] Trans. vol. 32, 1910, p. 626.

tons short of the necessary supply of coal to carry on our industries. The only difference of opinion on the subject is whether it will be 6,000,000 or 10,000,000 tons. Mr. Storrow called together a number of engineers in Boston, representing all the different societies, and through their influence a committee of five or six was named to take charge in Massachusetts of the work of effecting this 6,000,000-ton reduction in the demand for coal. The committee appointed, it may be said, was made up of men entirely from this Society.

It is no small task to present this case in every place in the state, but I have agreed to do that, or to call on members of our Society who live in New England to help in doing it. The great appeal to men who live in New England is a moral appeal. It has never failed yet. Behind the conservation of coal is a larger question. I call it one of the great moralities before the American people—to be frugal in the resources that God Almighty has put here for us to use in the future. That is what we ought to think of when we go into the fuel question.

During the past year one of the great firms here in Worcester formed a conservation committee, made up of employees, who had the power to enforce a certain policy to effect economies upon the entire company. It amounted to establishing a fuel board in that plant and is what we ought to bring about in every concern in the state, so that the men will work together willingly to save fuel. They discovered, after having gone through the month of December on the old system, that during the months of January and February they saved 40 per cent of their coal by economies outside of the boiler and engine rooms. They did not direct their attention to reducing the amount of coal for a certain quantity of steam, but to the use of the steam power after it was handed over to mills that had no responsibility for producing it. Forty per cent saved, when it was within their power to have saved it any time in the last twenty years!

I want to place forcibly before you the absolute importance of taking up economies and savings within the establishments where they are to be effected. After all, this is largely a question of good common sense, as are the bulk of the problems in our profession. In any establishment it is a matter of good-will and coöperation shared by everybody from the apprentice to the highest officer in the place, so that every individual has the feeling that he, too, is making some contribution.

If we can only put that into our factories and into our homes and into this country, if you can only take that back home with you, our boys on the other side are safe and they will do their task with the smallest loss. I feel more strongly than anything else that the Almighty has decided this long, long ago: those win who deserve to win. In God's name let us deserve to win. [Great applause.]

THE SMALL INDUSTRY IN A DEMOCRACY

By GEORGE H. HAYNES,[1] WORCESTER, MASS.

THE purpose of this paper is to raise question as to some of the industrial implications of democracy,—democracy which in government is set before us as the goal worth all this outpouring of blood and of treasure, this world anguish.

A generation ago, Gen. Francis A. Walker, then the dominating figure among American economists, declared: "For one, though believing thoroughly, so far as politics are concerned, in a government of the people, by the people, for the people, I see nothing which indicates that, within any near future, industry is to become less despotic than it now is. The power of the master in production, 'the captain of industry,' has steadily increased throughout the present century."

Though describing industry as having become "despotic," in his Political Economy (1887) which for a decade became the standard text for American college students, General Walker did not think it essential to give a single paragraph to the corporation as a form of business organization, nor a page to the modern monopoly problem, and he made no mention of such a thing as a "trust." In the 30 years that have since passed, concentration and consolidation have gone forward at an unprecedented rate. The new era in industry may be admirably illustrated by examples from the tale told last evening by Mr. Washburn. Thus, the enterprise started by Ichabod Washburn becomes the Washburn and Moen Company. It next is absorbed by the American Steel and Wire Company, with many plants in Worcester and elsewhere. And presently that company becomes one of the many concerns, aggregating nearly 150 plants, consolidated into the United States Steel Corporation, with a capital stock of $1,100,000,000. The net earnings of this greatest of American industrial corporations were $295,000,000 for the past calendar year, and it carries on its payroll some 200,000 employees.

There are those who see nothing of challenging inconsistency presented by the development of such an *imperium in imperio*, of such an autocratically controlled industrial army—the largest among many—in America, the leader of the world toward the goal of democracy in government. They see no incongruity in the fact that we compel the children of this host of workers to attend our public schools, and we urge the newcomers to become American citizens—at any rate, we are going to urge them to do so, from now on!—and we thrust the ballot into their hands, so that in our accepted democratic theory the vote of the newly naturalized Syrian or Polander or Croatian counts for as much as does the vote of Judge Gary himself in determining who shall be the chief executive of Gary, Indiana, or the chief executive of the state of Pennsylvania, or the chief executive of the United States of America. Yet that workman's vote or voice is not to be counted at all in determining matters as intimately concerning his own life as the conditions of his daily work or the amount of his daily wage. These matters are determined for him by the management constituted by the control of 51 per cent of the stock of the New Jersey corporation. Stock ownership by the workmen, to be sure, is encouraged by the United States Steel Corporation, as by many another far-sighted and progressive concern; yet it is safe to say that in not one large corporation in a hundred does the stock vote of the workmen amount to enough to qualify at all the essentially autocratic management of the enterprise.

Nor is the situation greatly bettered, so far as consistency with political democracy is concerned, if the workmen be organized so that collectively they may drive a hard bargain to enforce their own demands. It used to be said that Russia was governed by a despotism tempered by fear of assassination. In democratic America, today, there is many a great industry which is controlled by an autocracy tempered by

[1] Professor of Economics and Political Science, Worcester Polytechnic Institute.

fear of revolution among its workmen in the form of a strike or sabotage.

And yet how many of us have reached the point where we believe that democracy in industry is coming, and ought to come? A striking forecast has recently come from the man who was the first president of the United States Steel Corporation, who later became the head of the company that runs the largest armament plant in the world, yet who, at the present moment—his willing service commandeered by the Government—is at the head of our Emergency Fleet construction. Mr. Charles M. Schwab is reported as saying: "The time is near at hand when the men of the working class—the men without property—will control the destinies of the world. The Bolsheviki sentiment must be taken into consideration, and in the very near future we must look to the worker for a solution of the great economic questions now being considered. I am not one carelessly to turn over my belongings for the uplift of the nation, but I am one who has come to a belief that the worker will rule, and the sooner we realize this, the better it will be for our country and the world at large."

The essence of democracy, in its industrial implications, is not to be found in equality of size, or wealth, or strength. Such equality is neither desirable nor possible. The motto of democracy in industry should be that of Carnot's army of the French Revolution: "*Carrière ouverte aux talents.*"

We recognize that in a democracy the individual, however humble his station, has a right to life, liberty and the pursuit of happiness, a right to the protection of his health and safety, and to educational opportunities which shall give him a fair chance to develop according to his ability. And the war is teaching us, more plainly than we ever saw it before, that, on the other side, in a democracy the State has a right to expect from its citizens equality of sacrifice, in the sense that sacrifice shall be gaged according to their several abilities to bear burdens.

In a democracy, the industry—small as well as great—has its rights, entitled to careful safeguarding; and it has likewise its duties and special services, upon the rendering of which the very destiny of the State may depend.

Democracy is best held sane and secure against attack, if the field of enterprise is kept open for men with a capacity for leadership. At present in the United States there is little to be feared from the I. W. W. or Bolsheviki. But there is grave danger for the future if no heed is now paid to the causes producing these movements, and if the field of enterprise shall seem closed to all but those of wealth or "pull."

In the field of industry as in the field of government and on the field of battle, democracy is on trial. Every forward-looking man anticipates that the industrial testing of democracy after this war will be more severe than ever before. In its relations to industry democracy must develop efficiency equal to that of autocracy, else it is doomed to defeat. But efficiency in industry, as in war, is not alone a matter of training or equipment or centralized control,—it is a matter of the spirit, of morale. Events of the past few weeks have proved that the morale of liberty-loving citizen soldiery may offset in no small degree the superior training possessed by professional fighters. So whatever conduces to better morale in industry may more than counterbalance some other highly valued elements of efficiency. In two respects, as I shall attempt to show later, the small industry distinctively and strongly does conduce to better morale: (1) in the enthusiasm which it evokes in the ambitious young employer who is managing an enterprise which is his own; and (2) in the team play which is worked out between employer and workman.

Of course, democracy must find methods not inconsistent with its own spirit to get the greatest industrial enterprises accomplished. Democracy does not imply that in the twentieth century the dial is to be turned back and that giant industries are to be split up into small units, or that a limit is to be prescribed beyond which an industry must not expand.

Democracy does imply that industries, great and small, shall be given scope to develop their capabilities up to the point where their further expansion would hamper that of others, or would prove injurious to the public interest. A generation of fumbling efforts to work out the state's proper relation to industrial control has brought into recognition some things which 40 years ago were strangely blurred.

In the first place, we recognize far more clearly than when the Sherman Anti-Trust Law and the Interstate Commerce Law were enacted, that many industries are inherently monopolistic, and that any effort to force competition in them is doomed to failure and can result only in increased cost and lessened efficiency of service. In this broad field, public interest is best to be subserved either by private operation under thoroughgoing regulation, or by government ownership and operation. Right now, under stress of war, weighty experiments are being tried out, which will throw much light on the monopoly problem.

In the second place, it is now recognized that in the so-called "trust movement," where no element of genuine monopoly has been present, a large factor has been the desire to secure the economies of large-scale production. This is a sound and constructive motive, and democracy is concerned to have such economies attained, to the extent that does not interfere with some higher or more essential purpose.

In the third place, it is obvious that certain enterprises must be conducted on a giant scale, if at all. A copper-smelting plant, a sugar refinery, a powder plant, locomotive works, as such enterprises are now conducted, may well involve an initial investment running up into the millions. The scale most conducive to economical production is not to be predetermined by any rigid or general rule. It must be worked out in each industry and in each community according to the conditions which conduce to greatest efficiency. Each enterprise should have a fair chance for a start and for normal growth, according to the effectiveness which it develops.

Democracy craves variety and individuality in industrial development. It needs the small industry not less than the large. The point which I wish to emphasize is, not so much that in a democracy the individual enterpriser needs the help and protection of the state, as that the state needs the widely distributed initiative and enthusiasm of ambitious young enterprisers.

Democracy needs to avail itself of the varied industrial talent and aptitudes of the many, and not merely of the genius of the few. There is another and a more important concern here involved than that of getting a maximum output produced at minimum cost. It is the calling forth of widely diffused and varied industrial leadership. "The magic of private property turns sand into gold." It means much for the strength and stability of a democracy, if the man with capacity for industrial leadership finds scope for developing his aptitudes as his own master, in the enterprise of his own starting, and not as a foreman or as a member of the staff of some giant corporation. Right here lies a cardinal difference between industrial democracy as we would see it develop in the United States and the type of socialism which many fear. Is it not possible to keep open the door of opportunity and enable the young man to discover and develop his own aptitude, without at the same

time making him the servant of the state, subject to a repression no less galling because imposed at the behest of a majority?

In recent years there has developed a new and discriminating appreciation of certain advantages of the small plant in industries which are not inherently monopolistic or in which the economies of large-scale production are not a dominant consideration. Perhaps foremost among these advantages is that which relates to the element of *quality*. America has wrought her most distinctive miracles in quantity production. Ford automobiles, to take the most notable example, are turned out by the million. But during the past year we have had our illusions removed as to the speed with which the highest type of fighting aeroplanes can be produced. Where the craftsman skill and precision are needed, more trustworthy products can be secured in the small shop than in the mammoth plant. A second advantage is found in the direct and intimate relation between office and shop in the small plant. Here the workers are still *men*,—yes, individuals, even, in the thought and under the eye of the superintendent or employer, while he is a distinct and knowable personality. This has not a few important results. In the small shop decisions are transmitted from the proprietor-manager straight to the workmen, and are carried into effect at once. Said one of our Institute graduates, a few days ago: "During the past six months we have nearly doubled our output, but we've added only one man to our office force. That puts us all under a good deal of strain." "Why not put more men on your office staff?" I inquired. His reply was: "That would mean just so much more red-tape and complication. When I first went with the firm (less than ten years ago), there were in the office just Mr. A. (the inventor-proprietor), Mr. B., his partner, and one other man. *Then* things used to hum! But the more men you get in, the more cards and reports have to be made out, merely to insure *the same degree* of efficiency."

Leadership "carries" better in the small industry. The proprietor's personality and enthusiasm can lay hold upon 25 or 50 men, whereas to a force of 500 he would be simply "the boss." *Esprit de corps* and morale are of natural growth in the small shop; they are hard to develop and maintain where there is no human contact between the employer and the workmen, and where the workmen are not personally known to one another. In the small shop there can be brought home to the individual workman the direct interest which he has in maintaining both the quantity and the quality of the product; he can be brought to see clearly how his own work is discredited and his own wage lowered in consequence of the soldiering or waste of material by any member of the working force. It goes without saying that the mutual understanding between employer and employees in a small industry is a strong influence in lessening the frequency and the seriousness of labor controversies.

In fact, the advantages of the small shop are so obvious that in these days of giant corporations some of the most interesting and promising experiments in industrial management are in the attempts to reorganize production "on the small-shop basis," assigning to a superintendent and small force of men the making of a particular part or the completion of a certain series of processes in the turning out of the finished product.[1]

If it be granted that the small industry in many fields of production has distinct advantages, and that the easy and natural progress from able and ambitious workman to proprietor is accordant with the spirit of democracy and tends to safeguard it from developing industrial Bourbonism on the one hand, or industrial Bolshevikism on the other, the question presents itself: What chance has the small industry in the democracy of today? Is it getting a better or a poorer chance than a generation ago? To what extent and in what ways should a democracy, in its own interest, seek to insure that chance?

Here the first step, thoroughly in accord with the democratic principle, is to see to it that the field of opportunity is not narrowed by encroachments of monopoly not controlled in the public interest. Despite the contemptuous sniffing with which not a few self-styled "hard-headed business men" have referred to the "New Freedom" programme, I venture to believe that the spirit embodied in the Clayton Anti-Trust Law and the Federal Trade Commission Law is constructive and deserving of approval. Those laws attempt reasonable definition, where the Sherman Anti-Trust Law introduced sweeping prohibition which hastened the very development it was intended to curb. Experience has shown and doubtless will continue to show defects in these laws needing correction. But they merit a better spirit of coöperation than in many quarters they have received. The present moment in the world's history is a time more appropriate for sincere and thoroughgoing study of the ethics of business than for disdainful ridicule of any efforts to restrain unfair competition.

But many a small industry fails to "make good" not because of unfair practices on the part of rivals, nor from any lack of inventiveness, resourcefulness or managerial ability on the part of its enterpriser, but because he encountered exceptional difficulties in securing some one of the elements requisite to its success. If—as I believe—it is essential to the safety and stability of democracy itself that its life be constantly renewed by the upgrowth of small industries, by the direct progress of ambitious young workmen into the ranks of proprietors, what steps should a democracy take to remove obstacles to such progress and to insure to the small industry a reasonable chance to work out it own salvation?

"Paternalism!" someone exclaims, at the mere raising of that question. But to my mind "paternalism" conveys the idea of coddling a weakling, to make things easy for the pampered child. It seems misapplied when used with reference to government action for the assuring of equitable industrial conditions essential to the safety of democracy. Nevertheless, it must be acknowledged that that way danger lies. The history of the protective tariff affords enough illustrations of the possibility that government action, ostensibly in the public interest, may be so designed and carried into effect as in some instances to benefit the few at great cost to the many. That there is some liability to abuse is not to be denied. However, the motive here advanced is not that of fostering any particular enterprise but rather the giving to small industries a fair chance, in order that by their growth they may safeguard democracy by lessening the danger of the development of a basis for class consciousness.

I—Power

All industries here in view are users of power. The obvious implication of democracy—though it has secured but tardy recognition—is that nature's sources of power should be made generally serviceable to the community as a whole, and should not be exploited primarily for the profit of the favored few. This idea underlies the recent movement by

[1] See the Small Shop System, by Peter F. O'Shea. An interview with Mr. F. O. Wells, president of the Greenfield Tap and Die Corporation. This article is soon to appear in *Factory*.

the National Government and by several of the states for the survey of water powers and for their conservation in the interest of all the people.

Most of the modern electric-power enterprises have been built up and are controlled by private concerns; a large proportion of them, scattered the country over, are in the hands of a comparatively few corporations which specialize in such enterprises. They are, thus, in position to bring to bear the highest engineering skill upon the solution of all technical problems, and they possess certain marked advantages in relation to maintenance and management. Here democracy is confronted by the tremendous problem of the government's relation to such enterprises,—of government ownership, with its diverse political and economic implications. A number of cities have been trying experiments under varied enough conditions to make their results of considerable interest and significance. Without exception, so far as I have observed, they report a substantial reduction in the rate made by the private corporations—it was 10 per cent in Seattle—dating from the first serious agitation for a municipal plant.

It cannot be stated too strongly that a conclusive comparison of the service rendered a community by a municipal plant and by a private corporation in competition with it can be made only by an expert, on the basis of painstaking investigation. The power rates of municipal plants are attractively low. But it must be borne in mind that those rates are in a sense not economic but "political,"—rates lower than could be made by any corporation which had to pay taxes, or which could not have its deficits made up from public appropriations. Depreciation charges are likely to be figured differently in the accounting of municipal as compared with private corporations. There may be ample justification for the policy of the city's charging less than cost for electric power, just as for many years the Post Office Department was run with a view not to its paying expenses but to its rendering the maximum service in the development of the country. But if power rates are to be fixed on that basis, the policy ought to be frankly avowed. The question as to the comparative efficiency of service to be expected from a municipal plant as compared with that of a private corporation involves many considerations which cannot be reviewed in this brief paper.

Pacific Coast cities have been pioneers in selling electric power for manufacturing purposes. A comparison of their rates would involve a maze of complications entirely inappropriate in a paper of this character. A quotation from the power rate card of a single city may serve to indicate on what easy terms the starter of a small industry may there secure his power. In Los Angeles, California, the use of the aqueduct has made possible commercial power rates running from 4 cents per kw-hr. for the first 100 kw-hr. in any one month down to 1.05 cents for from 3000 to 6000 kw-hr. Pasadena generates power by a steam plant using fuel oil, and sells her customers electric power at just one-third what it cost at the time when the city plant was projected. In Seattle the rate has been reduced to about one-quarter of what it was under the old régime, and the city's hydroelectric works are being greatly extended. In Tacoma, the city has been selling power since 1897, but made no special effort along this line till 1912, when the rate was reduced from a uniform 3-cent rate to a sliding scale on which the price for kw-hr. according to the load factor runs from 2¼ cents (where the load factor is 10) to 0.35 cents (where the load factor is 100). And these rates are reduced by one-third where the customer agrees to take the power at certain hours and to cut off all or a large percentage of his power during the low-water period. Since 1912 there has been a marked increase in the use of electric power. Forty-two different types of industry appear upon the list of small users of power; they include machine shops, rubber factories, shipbuilding plants, meat packers, smelters, lumber manufacturers, etc. No one who reads the list can doubt that the Tacoma motor-rental system is serving effectively to diversify the city's industries, and to make it easy for an ambitious young workman to start an enterprise of his own.

A most timely document is the Report on Electric Power Supply in Great Britain (made public in December, 1917) by the Coal Conservation Sub-Committee of the British Ministry of Reconstruction. What lends especial interest to this report is the fact that, by way of enforcing the necessity for a most serious consideration of the recommendations which they present, they repeatedly refer to the disadvantages which the British manufacturer is sure to encounter in after-the-war competition with better-equipped American enterprises. For example:

> In the United States the amount of power per worker is 56 per cent more than in the United Kingdom—if we eliminate workers in trades where the use of power is limited, or even impossible, we shall probably find that in the U. S. A. the use of power, where it *can* be used, is nearly double what it is here. On the other hand, not only are the standard rates of wages higher in the U. S. A. but living conditions are better. There is little doubt that in the U. S. A. the average purchasing power of the individual is above what it is in this country, and that this is largely due to the more extensive use of power, which increases the individual's earning capacity. The best cure for low wages is more motive power. Or, from the manufacturer's point of view, the only offset against the increasing cost of labor is the more extensive use of motive power. Thus, the solution of the workman's problem, and also that of his employer, is the same, viz., the greatest possible use of power. Hence the growing importance of having available an adequate and cheap supply of power produced with the greatest economy of fuel. (p. 7.) The present coal consumption would, if used economically, produce at least three times the present amount of power.

The Committee makes the following recommendations: (pp. 1 and 17)

> The present inefficient system of over 600 districts should be superseded by a comprehensive system, in which Great Britain is divided into some sixteen districts, in each of which there should be one authority dealing with all the generation and *main* distribution.
>
> Sites suitable for electric generating purposes should at once be chosen where water is plentiful and transport facilities good or fuel close at hand.
>
> Each district of electrical supply under a single authority should be a large area, with the greatest possible variety of electrical requirements and including populous centers of industrial activity.
>
> Power available from surplus gas or waste heat should be turned into electrical energy on the spot in local plants which would feed into the main distribution system.

At a time when for many months it has been necessary to subject this country's fuel supply to rigid control, on a day when many of the gas and electric light companies in New England have but a week's supply ahead, when Worcester manufacturers are facing the prospect of having to close their shops or curtail production for months, and when the bins of probably half the householders of this city are empty of coal and when no assurance can be had of more than two-thirds of a winter's supply, I have ventured to refer to this radical proposal, put forth by an eminent and responsible group of investigators, for the conservation of England's coal supply, and for the most efficient development of power therefrom, in the interest of all her people.

II Capital

How shall a starting industry secure capital? In the days of Worcester's early industrial growth, the necessary capital units were small, and might be drawn from modest savings, or secured in considerable measure from personal acquaintances. But now the situation is vastly changed. The new industry is likely to need a greater amount of capital at the start, and its founder's acquaintances are less likely than three generations ago to have the requisite funds.

At the present time, some New England banks are paying considerable salaries to their representatives who go about in the community helping farmers decide how to invest borrowed capital most successfully in the development of their home farms, with the result that three parties gain: the bank, in securing a safe investment for its funds; the farmer, in getting capital, together with expert advice as to its intelligent use in his own farm problem; and the community, in securing a greatly increased production of food crops. Similar interest and coöperation may be shown by banks in the case of the starters of other small industries. Some modification of coöperative banking, as worked out in Germany and Switzerland, may enable men of character and enterprise to borrow upon their pooled credit, for the starting of a promising industry.

IV Labor

At the present time the "help" question is one of the most disheartening elements in the manufacturer's problem. Trade schools and vocational guidance are some of democracy's newer devices for affording the boy some training in fundamentals and for discovering to him and to his parents what his real aptitudes are. Public employment agencies may serve to bring employer and employee together and help distribute the labor force to the points where it is most needed. But the fundamental evil of the present situation lies far deeper. Ex-President Tucker, of Dartmouth College, declares that "the social curse of industrialism as it now exists lies in its effect upon the disposition and temper of industrial workers." He points out that by putting the worker under the dominance of the machine, by subjecting him to various conditions not of his own choosing, and by depriving him of the stimulus and incentive to private ownership, industrialism has alienated the man from his job; it has taken from him "the zest for work, than which nothing is more necessary to social progress."

One of America's most eminent engineers, Mr. Charles P. Steinmetz, has said that in every industrial enterprise there are three principal elements that need attention,—the financial, the technical and the human. He added that the I. W. W. put in their appearance where the human factor is neglected and to the employer who disregards that human factor his admonition is: "The I. W. W. will get you, if you don't watch out!"

Right here is one of the great advantages of the small industry and a prime element of its importance to a democracy. In the small shop, relations between employer and workmen still remain personal, human. The great corporations of the present day are striving earnestly to solve this problem of the human element. They are calling to their aid the psychologist and the sociologist; they engage trained experts as employment managers, and organize elaborate welfare departments. But no scientific organization for "hiring and firing" and no wholesale welfare work can duplicate the results in efficiency and *esprit de corps* of the working team which can be achieved by the employer in the small industry.

In a paper recently presented before this Society, Mr. Richard B. Gregg has discussed "What it costs to hire and fire." He intimated that an annual labor turnover of 20 per cent was not exceptional, and cited cases where for several successive years it had run as high as 45 per cent, while in one department of a certain cotton mill it had last year gone over 500 per cent. The losses which such incessant shifting involve to the employer, to the workman and his family and to the community are appalling. Yet every person here knows employers in small industries who through years have kept a loyal working force, relatively permanent and having an interest and a keen pride in "their" shop, and the quantity and quality of "their" product. It was such employers and such workmen as these who gave to this Worcester community its immensely strong and diversified industrial development, so hard to maintain under the changed conditions of today.

V Research

In one respect the small industry has been at an unnecessarily great disadvantage. The day of hit-or-miss or rule-of-thumb methods is clearly past. Yet the small industry cannot conduct scientific investigations in elaborately equipped and expensively manned research laboratories of its own. Here is a field where government, federal or state, may provide coöperation along lines similar to those of the U. S. Department of Agriculture and of the state experiment stations. The Bureau of Standards is already doing something in the way of research work for private concerns. The laboratories of this Institute, as of scores of engineering schools and universities, have facilities which may help solve the technical problems of many a small industry, at a fraction of the cost which would be involved if the manufacturer should attempt to have this work done in his own plant.

VI Publicity and Marketing

One of the greatest disadvantages under which the small industry labors is the difficulty in getting its product continuously and effectively before the public. Private enterprise has not failed to note this need and to provide well-designed facilities to meet it. For example, the Bush Terminal Company, not content with providing the splendid buildings in connection with which manufacturing space, power, light, heat, railway and shipping facilities are furnished to its tenants, has spent \$2,000,000 to erect an "International Exhibit Building" at the very heart of the day-and-night activity of New York City, on West Forty-second Street. It is where every dealer would wish to have his show room, but could not afford to do so alone. This is genuine, scientific coöperative service on the part of a far-sighted corporation, and some small industries may find great advantage in availing themselves of this opportunity.

Considerable saving and enhanced efficiency could be secured if manufacturers in related lines would coöperate in their sales work. The automobile shows offer a spasmodic and spectacular example of what may be worked out in more simple and modest fashion in many lines of industry. The coöperative fruit-selling agencies of the Pacific Coast states and the produce-marketing organizations in other parts of the country present familiar illustrations of coöperative selling. Nor is this a matter unworthy of governmental interest and aid. The medieval fairs brought business and prosperity to the towns which held them. Even in war-stricken France, the past year, certain expositions have been maintained. Our own country affords illustrations of municipal industrial museums suggestive of a development which might be greatly extended, the

ers providing ample and suitable halls and facilities for the display of the high-grade products distinctive of its industry,—doing this not as a matter of favoritism and patronage, but taking it upon itself to advance thereby the interests of the whole city as an industrial unit, in the spirit frequently shown by a progressive chamber of commerce.

An attempt has here been made to analyze some of democracy's implications in the industrial field, and to emphasize some aspects of the American industrial system which bid fair to subject our form of government to severe strain. Emphasis has been laid upon the small industry's consistency with the spirit of democracy, and its tendency to strengthen democratic institutions, and some ways have been suggested whereby through public or private coöperation the small industry, in the interest of democracy, may be given a better chance of success.

At any time these matters might have been considered of some academic interest; but right now they seem to me of a new and vital significance. I believe that it is an accurate forecast that in the future the historian will find the chief significance of this World War not in the dynastic and territorial changes which at present seem to us to be of such prodigious moment, but rather in the world-wide social and economic upheaval and revolution, for which the war is now preparing the way, and of which Russia affords a portentous example. Even before the outbreak of the war, in America as well as in Europe there were abundant signs that convulsion was impending.

The coming of peace will bring a period of tremendous readjustment. Back from the front will come scores of thousands of young officers, and millions of young soldiers, to be reassimilated into our economic and political life. That process will be vastly different from the readjustment which followed the Civil War. Back to our industrial centers these young men are to come, with a changed outlook upon life. Men who before the war had been plodding wage earners, hardly stepping outside their deep-worn rut from one year's end to another, and with no suspicion that life had anything else in store for them, have now seen other lands, other customs. They have had a great illumination. They have taken part in the greatest enterprise in the history of the human race. They have learned team play, and the immense effectiveness of disciplined coöperation. They have found within themselves unsuspected power to dare and to do and to lead. Let no one fancy that the return to the ranks of industry of these hosts of young crusaders, who have gone through hell to make the world a decent place to live in, will not add a tremendous ferment to the social and economic unrest. They are going to demand that democracy in government find its counterpart in democracy in industry; that life yield them something more than the day's wage,—that it give them something of the zest of adventure, of opportunity for advancement, of chance for independent leadership. Where shall these ambitions and restless energies find an outlet?

In the strain to which our institutions are sure to be subjected in the years that lie immediately before us, the small industry may render service of incalculable importance to American democracy. It offers scope for ambitious young men to rise from the ranks to positions of leadership. It keeps relations human between employer and workmen. It gives the lie to the class-conscious radical's assertion that America is divided into two hostile camps, the bourgeois and the proletariat. When the Allies shall have succeeded in making the world safe for democracy, the small industry may have no small part in making democracy safe for the world.

THE TEXTILE INDUSTRY IN RELATION TO THE WAR

BY J. E. ROUSMANIERE, NEW YORK, N. Y.

I AM concerned with the selling of cotton goods. Before the war the firm with which I am connected sold to the Government a large amount of goods for the Army and Navy. We have, of course, sold them a much larger amount since the war has been on, and since I first went to Washington at the request of one of the representatives of the Government, to serve on a committee, I have given a rather large part of my time to helping the Government, so far as I could, to obtain the textiles of which they were in need, particularly cotton textiles, with which I am most familiar.

Those who have not looked into the matter carefully will be surprised at the need there is of textiles in all departments of the war-making machinery of the Government. In fact, it has been a theory of mine—which has not worked out in practice—that by reason of the lack of cotton and wool and rubber Germany's war-making ability would be restricted. But she is making war now probably better than she has in the past, and yet with the enormous use that is made of those three articles here, and on the theory that Germany has not received any for the past two years, it would seem as if she must get to the end of her rope.

Among the textiles used in war are cotton woven goods, woolen woven goods, cotton knit goods, woolen knit goods and same silk goods. There are four grades of woolen goods: overcoating, 32-oz.; suiting, 20-oz.; blanket, and woolen shirt. There are also various weights of cotton duck used for tentage and for wagon covers and the like. The cloth is used by the Government usually in the dyed state, but owing to the great need of haste they have been using large quantities in the gray state until the dyeing capacity of the country could be adjusted. There are also uniform cloths, fiber-dyed—that is, dyed in the cotton and then spun and woven, as used by the marine corps, or spun and then dyed, as used by the Army. There is also a silk material used in making cartridge bags, which, unlike cotton, does not leave any residue in the gun.

When the war began the Government did not have any stock of goods. There had been trouble with Mexico the summer before and practically all the stock of goods in the country had been taken by the Army and had been made up and used. The first time we went to Washington the Assistant Quartermaster General told us that he wanted 47,000,000 yd. of 12-oz. duck for tentage within nine months. There were three or four manufacturers present who made such goods, and we all agreed that 20,000,000 yd. could not be made in a year, much less 47,000,000 yd. in nine months. But the industry bestirred itself and is now supposed to be making 90,000,000 yd. per year, and has bettered the production which the Assistant Quartermaster General asked for a year ago last March. We all had commercial orders at that time to keep our looms busy, but in every case the man whose commercial business was interfered with has accepted the decision of the Government, and so far as my personal experience goes, the whole textile industry, both in the manufacturing and in the consuming end, has acknowledged the fact that the Government must be taken care of before anything else is done.

The same question has arisen within the last two months. When the drive across the water began and it was seen that the Army must be increased very rapidly, the buying that

[1] J. Spencer Turner Company.

had been done on the established program at that time was found to be insufficient, and about the middle of April instructions came to us from the Government that we must deliver no more goods on our commercial orders of the class that is used in uniforms or for linings until the first of June, and for five or six weeks there were no goods delivered on commercial orders—the Government took them all.

In order that you may understand some of the needs of the Government for textiles, let me repeat a few of them, taken somewhat at random: The amount of woolen cloth needed for uniforms, for blankets and for overcoats for 3,000,000 men is enormous. A part of the wool used comes from Australia. Our Government went to the British Government, who had bought the entire clip in Australia, and obtained from them some of the wool, which in turn was doled out to the manufacturers who are to make woolen uniform cloth. One contract placed with one firm on woolen cloth at one time amounted to $57,000,000.

Then there are the cotton uniforms that are worn in summer; and the cotton uniform cloth required for 3,000,000 men is an enormous amount. Let me suggest some new demands which had not arisen before. One new use for wool that came up suddenly was occasioned by the demand for woolen puttees. United States soldiers had never worn puttees before and they do not wear them much now in this country, but it was found that the weather in the trenches, particularly in the winter, made the use of leggings impossible—that the men's legs became so cold that they could not stand it and they needed something warm to wrap around them.

Immediately on war being declared the gas-mask question came up and the Government had to supply them for all the troops going across the water. It requires a very closely woven piece of fabric for the face cloth that contains the bull's-eyes, and heavy canvas for the pouch holding the aluminium container in which the chemical is placed and through which the air is sucked in through the rubber tube. These goods had to be gotten together quickly and mills had to go on to fabrics which they had never made before, but on the whole it has been done remarkably well. Now they also provide gas masks for horses.

One question that came before the committee early in the war grew out of the fact that the hospital corps required 500,000 suits of pajamas, necessitating about 3,000,000 yd. of goods. The Army hospital corps had always used pajamas, but in amounts requiring not over 100,000 yd. a year; and it so happened that they had adopted a standard which was a practical manufacturing proposition for only one mill. But the mill could not make 3,000,000 yd. as quickly as the Army needed it, and therefore a new pajama cloth had to be arranged for—a sort of chambray weave.

The Government has just purchased in the market 70,000,000 yd. of denim for overalls and jumpers and other purposes for the men in order to save their uniforms while they are working. The men who went abroad first were equipped with blue denims, but Pershing cabled back that blue denims were too conspicuous for the hostile aviators and therefore the Government had to change to the less conspicuous brown goods.

All of these problems have been solved by the industry and I think it is entitled to a very great deal of credit for the way in which it has adjusted its methods to the making of new cloths at short notice.

The amount of sheets and pillow cases needed for the hospitals was also large. The Government has lately placed an order for 240,000,000 yd. of bandage cloth for the Navy, for the Army, and for the Red Cross, consolidating the purchase.

The Navy also buys a very large amount of bleached twills for white uniforms. This is much the same cloth as the Army uniform cloth, but made a little wider and then bleached.

The use of heavy ducks by the Government is very large. I remember last fall at one time the General Staff in Washington received a requisition for 13,000,000 yd. of No. 4 duck, a very heavy material weighing almost a pound to a yard, and 22 in. wide, for use in tarpaulins. Another need of duck has lately arisen in the Emergency Fleet Corporation, which has just placed a large order which is needed promptly in order to complete the boats now being built at various shipyards.

Probably the greatest change was in the aeroplanes. Aeroplane wings had hitherto been made of linen, and while the practice was different in Italy, it had been the theory both in France and England that cotton cloth would not do for wings. Cotton has a tendency to expand and contract with the dryness and the dampness of the atmosphere, and it was also felt that cotton wings when shot by a shell would tear, whereas linen has very great tenacity and does not tear. But they experimented in many ways and developed a cloth made from specially treated cotton yarns. It is now said by the aeroplane service in Washington that that cotton cloth is standing up quite as well as the former linen. But it took a good deal of experimenting to convince the personnel that it would do as well as linen. However, so far as I know the battle planes are still equipped with linen cloth, a little of which we get through the British Government, but the practice planes and the slower planes are equipped with the cotton fabric.

Beyond these very large needs are those for covers for the 3-in. and the 6-in. and larger guns, which require a good deal of duck, taking it as a whole. And in addition a new belt had to be manufactured—a new apparatus to carry hand grenades—something that had not been used much by the Army before. Then there is the matter of truck covers; for one of the first orders of trucks over a million yards of goods was needed.

A large part of all these goods have been made in New England. The heavy ducks have been made in the South, but as many of the heavy duck mills in the South are owned and controlled in New England, they may be considered New England enterprises. Various of the mills in New Bedford are making the aeroplane and the balloon cloth. Fall River and other places are making the bandage cloth. The army duck is being made largely in Lowell and Manchester. The uniform cloth is being made very largely in Manchester, one concern turning out 500,000 yd. each week. The woolen cloths are made all over New England. And New England, taking into account its munition factories and its textile enterprises and others, seems to be doing its fair share and possibly more than territorially would be allotted to it in supplying the needs of the Government for carrying on the war.

As I said before, I feel that the textile industry as a whole has responded splendidly to the demands made by the Government. And I have no doubt but that these very industries have called on you for advice as to how they can make over their plants to manufacture the fabrics which the Government most needs, and increase their production—which is attempted in every plant in the country so far as labor conditions will permit. And I know that when such requests are made of you by the textile industry you will do everything that you can to help them meet what appears to be at first sight the overwhelming needs of the Government to supply its armed forces in all its branches. [Applause.]

CONVERTING A FACTORY FOR MUNITIONS MANUFACTURE

BY JOHN S. HOLBROOK,[1] PROVIDENCE, R. I.

THE Gorham Manufacturing Company, probably the largest silversmiths in the country, if not in the world, has been identified particularly with the sterling-silver trade. It has also made a considerable amount of silver-plated ware and of late years has produced a large quantity of bronze statuary, structural and ornamental bronze, besides various ecclesiastical wares such as pulpits, altar rails, chalices, etc., at its Elmwood plant in Providence, R. I. The step from this sort of work to the manufacture of metal goods for war munitions is consequently not as great as at first it might appear when we speak of silversmiths as munitions makers, for our men are trained in the handling of metals and in the use of machinery adapted to their manufacture whether drafting, spinning, stamping, or casting, and we therefore were not handicapped as a strange concern might have been in the knowledge of metal handling.

Very shortly after the war broke out the Allied governments came to this country for munitions and we began to receive inquiries. Our superintendent at that time was Capt. O. V. Kean, a graduate of West Point and thoroughly familiar with ordnance work and the ordnance schools, and he naturally became interested in these inquiries.

The first negotiations entered into were with the British Government for 50,000,000 brass cups for small arms and the same number of cupro-nickel cups for Serbia, these being made in knuckle-joint presses which we already had on hand in our machine shop. The cupro-nickel cups were contracted for on April 14, 1915, and were delivered on time.

On May 11, 1915, we contracted for 50,000,000 brass cups to go with the cupro-nickel, but found our presses were too light to handle the heavier gage, which necessitated the purchase of new presses.

At the same time the French Government appeared in the market for cartridge cases for the 75-mm. gun, considered by many the most efficient weapon of the war. This was an entirely new proposition and involved a large expenditure both for new buildings and equipment, but after careful consideration the directors of the company felt that the contract was profitable and that as a matter of patriotic assistance to the Allied governments, with whom our sympathies even then were very strong, we should take the contract. They therefore authorized the building and equipment of a new one-story brick brass-case shop, 360 ft. 6 in. by 122 ft. 8 in., which has cost approximately $500,000.

The first contract with the French Government was for 500,000 of these 75-mm. cartridge cases, which upon completion was followed immediately by an order for 975,000 more. These orders were filled so satisfactorily that when we entered the war the French Government went out of their way to compliment our work to the United States Government.

The French Government contracts were followed by one from the Russian Government for 1,000,000 brass cases for 75-mm. high-explosive ammunition, and another from the Swiss Government for 200,000 75-mm. brass cartridge cases of a still different type. Later the Netherlands appeared in the market and gave us a contract for 1,000,000 lb. of brass disks for their small-arms cartridges, as well as for 340,000 lb. of cupro-nickel cups. Also the Danish and British Governments each placed orders for about 225,000 lb. of the latter, and smaller orders were filled for the Norwegian and Portuguese Governments. It should be stated that each of these contracts required a different cup, slightly different in gage, height, thickness of bottom, etc., and that special metal had to be carried for each contract.

These various contracts had fitted us with a broader experience and we had built up a reputation and were ready to begin serious work for the United States Government when we entered the war. At the same time we have been able to do some work for the Allied governments in addition to our United States Government work.

The first U. S. Army contract came March 30, 1917, even before war was declared, and was for small cups, 6,600,000 each of the brass and of the gilding metal, the latter being for the U. S. Army bullet jackets. In May, 1917, a contract was closed with the Maxims Munitions Corporation for 275,000,000 each of brass and cupro-nickel cups for Italy. The first order for cases was placed May 1, 1917, for the U. S. Navy 3-in. landing gun—again a different case from anything we had made before and requiring an entirely new outfit of tools but not machinery.

Immediately on the outbreak of the war our plant was placed at the command of the Government both as to its special war machinery and as to the silver plant. The Navy contract was followed by one in August for a large number of 3-in. cases for the U. S. Army—again a different case from that for the Navy landing gun, and French 75-mm. cases, the Army having decided to adopt that gun.

The Government then began to inquire what we could do on grenades, and after some negotiations we took no less than four separate orders for grenades, and at the request of the Government built an assembling and loading plant at a cost of considerably over $250,000, at East Providence. This plant is designed for an output of 100,000 loaded grenades per day. Ground was broken in December, 1917, and work started in the plant six weeks later.

Our contract for the Navy landing-gun case was so successfully filled that the Government asked us to make a large number of the large 4-in. 50-caliber cases. Another plant was required for this work, as it is done almost entirely by hydraulic presses, and after some negotiations the old plant of the Providence Machine Company on Eddy Street and Allen's Avenue was purchased, new buildings erected, the old buildings repaired, and the machinery installed, and they are just beginning production. The plant's ultimate capacity will be 2500 per day.

In December, 1917, the Army placed an additional order for the 75-mm. cases with the proviso that if we finished them by August 1, 1918, we should continue and make an additional million. More than one million have been delivered and we expect to complete the balance well in advance of the date specified.

Early in 1918 the Government took up with us the question of our assembling and machining the Stokes trench bomb. This involved a further outlay for machinery, but there was space enough in the Allen's Avenue plant and we accepted an order for these, deliveries of which have already begun. We anticipate turning out 1500 per day on our automatic machines and may considerably exceed this.

The machinery directly engaged on our munitions work and bought for that purpose has a capacity of between 25 and 30 millions of dollars' worth of output per year on the basis on which we now work, which is that the Government furnishes

[1] Vice-president, Gorham Manufacturing Company.

For presentation at the Spring Meeting, Worcester, Mass., June 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 West 39th Street, New York. The paper is here printed in abstract form. All papers are subject to revision.

the raw material and we the labor and assembling. Contracts actually in hand total something over a third of this amount—between 8 and 10 millions of dollars. This, however, does not take into consideration any machinery in the silver plant, and finding that we had capacity over and above our usual business, we have taken a considerable number of orders for miscellaneous equipment of various kinds. The disposition of the directors of the company is to place the plant as largely as possible on work which is directly useful to the Government and assist in every way in the successful prosecution of the war.

Special Equipment

With regard to the tools which the Gorham Manufacturing Company has found necessary in order to arrive at the stage of production which it has reached in this work, the following particulars may be of interest: The machinery and tools of the silver plant have in the main been totally inadequate and impractical for the munitions work. Certain knuckle-joint presses which we had been using in the machine shop of the silver plant were used for bullet cups, as mentioned in an earlier paragraph, but the brass small-arms cartridge cups came from stock so heavy that it broke down our presses and we had to order special presses from the E. W. Bliss Company.

The equipment for the brass-case shop consists approximately of 4 cupping presses, 2 indenting presses, 15 rack-and-pinion presses, 4 heading presses, 4 tapering presses and 33 Bullard lathes. There are also marking presses for stamping the heads of the cases with their identifying marks and lot numbers. The cupping presses (E. W. Bliss Co., No. $77\frac{1}{2}$) are large presses for making the first cupping from the disk and are very powerful. The indenting presses were originally put in for work on the Russian and Swiss cases. As these are no longer made the presses are now used for cupping. The rack-and-pinion presses (E. W. Bliss Co., No. $66\frac{1}{2}$) are presses which make the second, third and fourth draws of the French cases.

The annealing ovens consist of three large annealing furnaces and a number of mouth and body annealers. Most of the latter have been built by us and are so arranged that the case is turned around in a frame and at the end of a certain number of minutes is presented at the opening, where it is withdrawn by a man with a pair of pincers.

For the grenade plant we purchased 14 acres of land in East Providence from the Rumford Chemical Company and erected one-story frame buildings covered with asbestos shingles, all of a temporary character. These buildings consist of two assembly rooms connected with the loading plant by a covered passage, power house, loading plant, detonator assembly room, shipping and storage sheds, office building, and of course the usual accessory buildings such as toilets, rest room, etc., together with two magazines. We have also arranged with the New Haven road for a spur track into the property.

The plant at Eddy Street and Allen's Avenue is built on land having an area of about 100,000 sq. ft. Here it was found necessary to erect one new building as there was none with sufficient height to take the huge hydraulic presses, some of which require 40 ft. of headroom. These presses were obtained in various places and are of the following capacities:

2—250-ton, 1st draw	3— 150-ton, 5th draw
2—250-ton, 2d draw	4— 210-ton, 6th draw
2—250-ton, 3d draw	1— 90-ton, taper
3—200-ton, 4th draw	2— 100-ton, header

There are also such small presses for stamping, etc., as may be necessary, and ten lathes. All the presses mentioned above, with the exception of one, which was used in the Russian indenting and which was moved from the Elmwood plant, are hydraulic.

To manufacture the trench bombs we were also forced to buy new equipment, consisting mainly of automatic machinery. This included three large automatic lathes for the machining of the head of the bomb, and automatic machinery for making the boosters and other parts.

The Question of Employees

In connection with the East Providence plant it may be stated that we have large storage magazines buried in the woods two or three miles away from the plants, where a large part of the nitrated starch is carried. This material is transferred as required to smaller magazines at the plants and only a few hours' supply is carried on the premises. From the smaller magazines it is brought underground by a pneumatic conveyor.

As to employees, we have 25 to 30 trades represented in the silver shop and some of these employees are at work on war materials, a few having been transferred as the opportunity presented itself through the slowing down of the silver shop. Most of them, however, are at work in the silver shop in their regular rooms, working on such war materials as bomb sights, powder cans, ramrods, etc. Our highly skilled men, such as die sinkers, designers, etc., we have not been able to transfer to this war work. The chasers have been kept busy on their regular silver work as have also the designers. The die sinkers have been of help in making tools, but most of the tools are made in the machine shop.

At the present time there are over 3200 employees on the payroll, which means about \$60,000 per week. The employees as a rule have stayed with the company and those transferred to the munitions work have been successfully trained under expert foremen acquainted with that kind of work. We found it necessary to add to the organization a number of expert men who had had previous experience in munitions manufacture and they are responsible for the training and upbuilding of the force.

The force of women employed has considerably more than doubled and it will be more than trebled by the time this paper is presented. The women employed in the Elmwood and Eddy Street plants are largely inspectors on brass cases and on parts of trench bombs and do not aggregate 100 altogether, whereas the number of women in the silver plant normally is in excess of 150. In the East Providence plant, or grenade plant, the women are in the majority, there being over 300 at present, which number will be increased to 500 to 600 when the plant is running at its full capacity. These girls are taken from the surrounding towns and are entirely untrained in the sort of work they are required to do. They assemble and load hand grenades, except as to certain processes which are entrusted to men. They are carefully selected and each one entering our employ has to be vouched for by at least two reputable citizens. We cannot afford to take any chances in a plant of this kind. The help is carefully picked and the inefficient ones rejected, this being shown by the large labor turnover—100 to 150 per week at the present time.

From the foregoing statements it will be seen that the problem of the Gorham Manufacturing Company has not been so much the transferring of present plant capacity and man power as it has been the building up of the new organization

to handle the work. The organization has been efficiently built up and its importance may be gaged by the fact that while the number of employees before the war was normally 1600 to 1800 at the Providence plant, it is at present about double that number, and all these new people have had to be brought in and trained. We have secured the help of able men, most of them acquainted with the production in their particular lines, some of them merely good machinists and mechanics. Of course this applies to the munitions only. We have found in the silver plant and bronze shop that our own foundrymen are able to handle any casting job which comes to us, and the munitions jobs which we have taken are far less complicated than the elaborate statuary moldings with which our molders are acquainted. The bronze-shop force, under the supervision of their foreman, has proved capable of handling such work as has come to them—ramrods, powder cans, thumb nuts, etc. An interesting part of this work is the work that is being done for the Government by means of our special process for depositing—on range finders and the like. We have had one or two contracts where very fine graduations were required and where the Government has found this process of great value for the reason that it might be depended upon to reproduce important parts absolutely without shrinkage.

FIRST GENERAL SESSION

THE first general session was held on Wednesday afternoon, June 5, in the Mechanical Engineering Building of the Worcester Polytechnic Institute. Vice-President Greene presided. The session was particularly well attended, and the discussion was keen, the first paper, entitled The Public Interest as the Bed Rock of Professional Practice, by Morris L. Cooke, ex-Manager of the Society, exciting so much interest that its discussion extended to half the proceedings of the session. This was to be anticipated from the nature of Mr. Cooke's paper, which, as the author frankly stated, was written for the purpose of determining what has been, and apparently continues to be, the attitude of engineering organizations toward society as expressed in their rules of conduct. Mr. Cooke's paper was one of the most important "policy" papers ever presented to the Society, and one which every member should take the time to read and discuss.

Mr. Cooke called attention to the inconsistency between the attitude of the engineers of the country toward the war—an attitude of spontaneous sacrifice—and their canons of professional practice as enunciated in the codes of ethics of their organizations. He thought this was a time to take stock and examine critically the orders under which society and its constituent elements are operated. Hence there can be no better time for a review of the regulations governing the professional practice of engineers. In this paper he sought to develop the engineer's concept of his public relationships and responsibilities as contrasted with such relatively minor obligations as those to the profession of engineering, to a client, to fellow-engineers, and to himself.

It seemed to him that the successful prosecution of the war was largely a question of our ability to keep it where President Wilson had placed it, on high moral ground. In a democracy this is not the work of one man, but of all the people. It is not our work purely as individuals, but it is our work in all our relationships, whether they be those of town life, church life, professional life, or what not. In these days of real peril, can we do less than write into our code that whatever our thought and practice may have been in the past, from this day forth it is unprofessional for an engineer to safeguard any private interest at the sacrifice of public welfare?

The chairman opened the paper for discussion, and Secretary Rice read a number of written contributions. In the first of these, by Charles M. Horton, the writer advocated rewriting our code by all means, but writing it in the spirit of what we shall do, and not what we shall not do. He thought the Society should "go big" at this thing and the members stand behind it to a man.

All the discussions which followed were in favor of Mr. Cooke's suggestion. All felt that engineers as useful and highly respected citizens should rewrite their codes in the spirit of the times, except one, Mr. Robert J. Hearne, who thought that if the present code were read as a whole, there was nothing in it that was directly antagonistic to the consideration of the public welfare by an engineer.

Secretary Rice opened the oral discussion by stating that he had been making the subject of this paper a religion in his administration of his office in the Society. He wanted to claim for engineers that they as individuals and idealists had contributed to the state of opinion in this country as to the object of this war, and the President has sensed these ideals of the nation and has phrased them.

He pleaded for a reconsecration of ourselves to the newer ideals, which he could express by no better phraseology at the moment than that recently expressed at the dedication of the Dayton Engineers' Club: "For the dissemination of truth and the promotion of civic righteousness."

L. P. Alford thought that a reframing of our code of ethics ought to be associated with a reframing of the statement of the aims and objects of the Society as expressed in the Constitution, and he presented a suitable resolution, which was carried.

Prof. W. W. Bird presented the second paper, on A Foundry Cost and Accounting System. This paper was developed as the result of experiments carried on in the commercial foundry at the Worcester Polytechnic Institute.

Professor Bird explained that the system was not a cost system, but was simply a signal system which could be kept up by the regular clerical force and which would give fairly accurate results of the profits from the foundry.

The system was based on the principle that the three most important items of cost are Core Labor, Molding Labor and Pounds of Castings Produced, and that each of the other items of cost was a function of one of these. Ledger accounts were opened for the three items, and by careful inventories at the beginning and end of each year the exact annual cost for each item was carried out.

Most of the criticisms of the system were to the effect that while it had been shown to apply to work of a very varied character, still the operations were fairly continuous. The discussers doubted whether the system would work so well for a foundry operated on different kinds of products.

Irving H. Cowdrey then presented a paper entitled Moisture Reabsorption of Air-Dried Douglas Fir and Hard Pine and the Effect on the Compressive Strengths. Though the interest in this paper was not so general, it was recognized that it embodied the results of an important research, which the

author presented in a remarkably clear and able manner. No discussion ensued.

The next paper was by Lieut. John L. Alden, entitled A High-Speed Air and Gas Washer. On account of the absence of the author, the paper was presented by title only. Three contributed discussions were read, by F. R. Still, W. H. Carrier and Henry P. Gale, respectively.

Briefly, the paper described a new type of washer, in which the entering dust-laden air is thoroughly wetted by the mist of the spray chamber, which removes much of the coarser dirt, and then is conducted through a helical conduit, where a large proportion of the remaining dust is thrown against the wet curved side of the washer, flowing off to the drain with the spent wash water. Due to high washing efficiency, only from 1 to 2 gal. of water are required per 1000 cu. ft. of air. Moreover, the apparatus is small, compact and of light weight, a 10,000-cu. ft. washer being but 5 ft. long and 5 ft. in diameter and weighing less than 400 lb.

That devices designed along the lines of the paper cannot be used in public buildings because of the noise they make was the criticism of Mr. Still, while Mr. Carrier considered that the principle described was not new, and varied hardly at all from the cyclone type of separator, provided with spray nozzles, which has long been used. Mr. Carrier considered the type as especially adapted for relatively small air quantities handled at high-fan pressures and where the air contains a great deal of coarse foreign material.

The last paper of the morning was presented to a small audience, but it nevertheless brought out interesting discussion and commanded attention. It was entitled An Investigation of the Uses of Steam in the Canning Factory, and was presented by Julian C. Smallwood. The paper was a unique one, in that it indicated the new types of mechanical-engineering problems confronting the special industries in war time. Heretofore there was not much mechanical engineering in canning—the essential consideration was the raw material, and no attention was paid to economy of operation in the process used. Now every attention was necessary. Members of the Society might take a lesson from this paper of Mr. Smallwood as illustrating new fields of application of their professional knowledge.

The paper described the various steam-using units in the canning factory, and suggested methods of increasing their efficiency, eliminating all avoidable wastes and utilizing all other wastes of heat as by-products.

Mr. W. D. Bigelow, of the National Canners' Association, supplemented the paper with a most interesting picture of some of the canners' problems, and pointed out the need for a publication which will give canners in general terms the essential facts of steam engineering as applied to the canning industry.

A. L. Webber spoke at length on his experiences in the sugar industry, especially with foaming materials. He gave some useful information on the velocity of circulation through evaporators.

L. B. McMillan called attention to simple ways in which the losses in canning apparatus could be reduced. B. H. Foster suggested the use of superheated steam to increase economy, and the author thought this was a possibility. Mr. Foster also thought that any attention which could be given to the conservation of fuel in canning plants at this time was commendable and worth the cost.

SAFETY EDUCATION SESSION

On Wednesday afternoon the session on Safety Education was held in the Salisbury Laboratories of the Polytechnic Institute, Vice-President C. H. Benjamin presiding. In opening the session, the chairman reviewed briefly the activities of the committees having charge of this educational work.

As a result of the interest of the officers of the National Safety Council and of the Workmen's Compensation Bureau, two committees were formed, the Committee of Eastern Universities, of which Prof. D. S. Kimball of Cornell University is chairman, and the Committee of Western Universities, of which Prof. Benjamin himself is chairman. He stated that the object of the committees was to stimulate educational work along safety lines and to interest the colleges and universities in it so that certain courses of instruction might be given in those institutions, and that the purpose of the present meeting was to contribute to that end. It was proposed further to furnish material, first in the form of lectures to be given by men eminent in the profession; second, in the nature of printed matter and of motion pictures, lantern slides, models, etc., for illustrative purposes, and thirdly, and most important, to formulate a brief system of education appropriate for this work.

Two papers were prepared for this session, one by L. A. De Blois on the Safety Engineer and one by George H. Follows on Safety and Welfare Work in the Engineer's Education.

Mr. De Blois' paper defines the field of the safety engineer and sets forth his goal as the reduction or elimination of accidents; it deals also with safety in construction, equipment and through supervision and education. Mr. Follows' paper takes up the question of safety as related to the engineer's education and outlines the commercial engineering course in the Carnegie Institute of Technology.

THE SAFETY ENGINEER

By L. A. De Blois,[1] Wilmington, Del.

Seven years ago I visited the Gary Plant of the Illinois Steel Company, in the interests of reducing the number and severity of the industrial accidents occurring in the plants of the Du Pont Company. The United States Steel Corporation, of which the Gary Plant was a subsidiary, had even then established an enviable reputation for its work in accident prevention. The report of this visit, which is now a very painful one for me to read, briefly disposed of the subject by stating that accomplishments at Gary could be roughly divided into two classes: mechanical safeguarding, which was excellent, and safety advertising, which the writer believed was undertaken to convince the general public that the steel industry, with a reputation for innumerable serious accidents, was not so black as it had been painted.

As I reflect on these earlier impressions and realize that over a year passed before I fully appreciated the injustice I had done the work at Gary, I wonder how many engineers and executives think today as I thought then—that safety engineering is merely a matter of safeguarding and advertisement. Yet, if I were asked for an opinion, I would say without hesitation that the foreman and skilled laborer in our modern

[1] Safety Engineer, E. I. du Pont de Nemours and Company.

industries have a somewhat clearer conception of and entertain a more cordial feeling toward the safety movement than many engineers and executives. It is partly for this reason that I am anxious today to persuade those who have heretofore considered the "safety first" movement as a fad or a frill that safety engineering is true engineering, that freedom from accident hazards should be a fundamental requisite in the design of structures and machines and a rigid necessity in plant operation, and that the greatest obstacle in the path of such attainment exists in a certain apathy to the safety movement among engineers in general and in a very definite and lamentable scarcity of trained safety engineers technically fitted to carry forward the work.

Field of Safety Engineer Defined

Let us attempt to define the field of the safety engineer's activities. His goal is, of course, the reduction or elimination of accidents. Analysis of industrial accidents shows that from 15 to 25 per cent are unavoidable. In the Du Pont Company, which I am happy to represent, these are the cases which we attribute to "Risk of Employment," "Unknown Physical Deficiency," and "Act of God," and they may be passed by with the brief statement that the number is gradually decreasing as the general knowledge of accident prevention broadens. Of the remainder, or avoidable accidents, between 10 and 20 per cent are caused by unsafe mechanical or structural conditions and are therefore possible of correction. This leaves 80 to 90 per cent attributable to human defects, that is, to the shortcomings of the individual—ignorance, carelessness, irresponsibility, indifference, disobedience, recklessness, horseplay and inexperience of the injured or fellow-employee—and to defects of system such as lack of proper supervision, discipline, etc., in the organization.

Obviously, the safety engineer may not confine his attentions solely to the elimination of those accidents for which his employer or company could be judged responsible under the common law of master and servant; he seeks to eliminate all accidents regardless of responsibility. In 1916 there were approximately 22,000 persons killed in industrial accidents in this country alone and 500,000 injured to the extent of losing over four weeks from work. Such wastage of man-power and production is in the aggregate enormous and constitutes a monetary loss of serious proportions. Unfortunately, its dollars-and-cents equivalent cannot be readily estimated. Workmen's compensation acts, which have largely rendered unnecessary recourse to suits at common law, practically ignore the question of relative responsibility and place approximately one-half the burden of accident compensation for all accidents on the shoulders of the employer. In establishing a rate of compensation, however, these acts make no attempt to evaluate life and limb but, based somewhat on the average net judgments for damages in suits at common law, aim rather to fix on the industries a fair proportion of the financial burden. It is not reasonable, therefore, to assume that the cost of accidents to the people of any state is represented by the total annual payments for compensation. Losses incident to injury or death are in one sense no more compensable than losses by fire are "covered" by insurance. In both cases there has been withdrawn from the nation's reservoir man power, or property representing man power, which can never be replaced.

A remarkable thing about the preceding analysis of industrial accidents is that it seems to apply equally well to any industry. The Du Pont Company, for instance, engaged in the manufacture of the most dangerous materials used in both industry and war, discovers about the same assignment of responsibility for accidents as does the cement industry. Mining, railroads, and other industries have the same experience. Moreover, the non-fatal and fatal accident rates on the Du Pont Company's plants do not themselves differ greatly from the rates of other and so-called "non-hazardous" industries. Both premises lead us directly to the logical, though somewhat surprising, conclusion that neither the nature of the industry nor the character of the materials produced or handled has as much effect on the cause, frequency and severity of accidents as the safe design and equipment of plants, the provision of a proper organization and constant supervision and the education of the working force into habits of caution and careful practices.

Have we not in this way defined the field of the safety engineer's activities and accredited him to all the provinces of design, equipment, organization, supervision and education? His influence must surely spread into each of them if consistent accident prevention is to be attained. But in reality they cover practically the whole vast territory of industrial projection, construction and operation.

Safety in Construction

There may be some who would at first object radically to the intrusion of the safety engineer's ideas in all these matters, especially since, as the exponent of "safety first," he is sometimes accused of interference with production. Let us examine this from the practical side. In the design of structures no engineer neglects the safety factor—which has become one of the tools of his trade—but who has not encountered stairs poorly designed, or probably not designed at all but left to the experience of the carpenter, the handrails of which, put there for emergency, must be used continually if an accident is to be avoided? We are all acquainted with new plants where aisles are dangerously narrow, where there is insufficient headroom, where machinery is inaccessible for repairs and valves are difficult to get at for manipulation or repacking. The safety engineer who sees these conditions and recognizes that accidents will inevitably occur may be met with the objection that they have not yet caused accidents and that expensive alterations are not justified and would hold up operations. These matters could have been corrected at less expense in the original design, and probably would have been if any one with experience had considered them from this angle.

Safety in Equipment

As for equipment, there are types of machine tools that are dangerous and others that are less so and equally efficient—the cylindrical-head jointer, for instance; and there is machinery that could have been better safeguarded by the manufacturer if complete guarding had been specified or if the pressure of demand by the trade had forced him to recognize that he must supply adequate guards or suffer through unequal competition.

In the field of general mechanical safeguarding there has been marked progress in recent years and some excellent standards have been formulated, among them those of the A.S.M.E. But the more difficult problems encountered are those arising from local application and arrangement of machinery, often peculiar to the industry in question, and others due to conditions abnormal to regular operation. As a fundamental we may as well admit that no machinery can be made foolproof in

its regular operation, and we must furthermore admit that conditions occur during adjustment, oiling, cleaning, repairs, replacement, etc., under which standard safeguards may be useless or may even introduce hazard. Evidently the solution of the problem of how to make the equipment as safe as possible under all conditions cannot be reached through mere general acquaintance with machinery of the class in question, nor by a casual inspection of the plant in normal operation. The problem will yield only to analysis after a painstaking study of all phases of operation and of conditions such as poor lighting, inaccessibility and congestion which are contributory to accident.

Safety Through Supervising and Educating the Workers

I have already stated that the majority of accidents are due to the shortcomings of human nature, to personal tendencies and traits in the individuals liable to injury, and to deficiencies in the organization which employs, instructs, holds in restraint and disciplines them. Here the safety engineer is upon different ground and must employ his knowledge of psychology and the principles of industrial organization. His greatest aids will be diplomacy, perseverance, tact and patience with the slow response to his insistent efforts to change the mental viewpoint. But there is in this branch of the work a principle so important that its neglect will bring failure in place of success; it is a clear recognition of the fact that the safety engineer can no more effect general accident reduction by his own direct efforts alone than the doctor can make a healthy community by curing the sick.

Through general education we may awaken a sense of personal responsibility in the man and emphasize the fact that it is necessary to "be careful," but this injunction is of little value if the actual presence of danger is not realized. Failing these, we must rely on the detection of dangerous practices among the men. The safety inspector or safety engineer should be able to tell whether a certain practice is dangerous when he sees it, but he cannot watch all the practices of a thousand workingmen, or even a hundred. The one class of men who can perform this function most efficiently are the foremen, but some one must instruct the foremen as to what is dangerous. This is the function of the safety engineer or inspector. However, an executive authority immediately above the foreman must first convince him, and continue to convince him, that he is required to properly supervise for safety. The plant manager must place himself clearly on record to the effect that safety is as important in the day's work as production or quality, for it is from him that the organization takes its tone. From the directing officials of the company must come moral and financial support. Thus the whole organization is involved.

I trust that in the foregoing I have shown that safety engineering with its interests in design, equipment, organization, supervision and education should have a place in every field of industrial enterprise and that it bears as well a very definite and important relation to all other branches of engineering. This relation is so close and its need so urgent that I am convinced that some instruction in the fundamentals of safety engineering should be given a place in the training of every young engineer.

Value of the Safety Inspector

I do not wish to be understood as underrating the safety inspector. There are many among them who are successfully filling worthy and responsible positions. There are many more who bear about the same relation to the safety engineer as the stationary engineer does to the mechanical engineer. Many are capable of making thorough inspections and recommending standard safeguards but are debarred by personal limitations from going very much farther. Yet in many plants nothing further is demanded. "We have a safety inspector and a safety committee"—the safety inspector of the "practical" type and the safety committee recruited from men in the shop who by some strange metamorphosis are expected to become suddenly expert in detecting hazards previously unrecognized. The real truth of the matter is that the safety committee proves very useful in detecting obvious conditions that the foremen and management ought to have observed and remedied long ago and the experience gained by the committeemen is good for them and opens their eyes to many common hazards.

Real Work for Real Engineers

The National Safety Council is the representative organization of the country dealing with safety. Since its foundation in 1912, its activities have extended until its membership now represents the employers of over 6,000,000 men. The safety of this vast army of workers should be in the hands of trained men, but there are few to fill the vacancies that exist today and the new positions that will be created tomorrow. It is not right that the onward march of the safety movement should be halted to permit its officers to be recruited and trained.

If there was ever need for a national campaign to reduce death and disablement from industrial accidents, that need is today. They tell us that at least three workers are necessary at home to supply one man at the front. By workers is meant producers—not hospital patients—and the war will bring us enough reconstruction problems in the employment of war cripples and returned soldiers without the problem of employing the many men crippled in our industries. Let us realize, then, that "safety" is not child's play, not a matter for "practical" men, not a passing fad, but real work for real engineers, and that the sooner we accept this viewpoint and shed our coats to the undertaking the less cause shall we have, when light comes, to regret the days of complacent inaction.

As Mr. Follows was not present at the meeting, Professor Benjamin called on Prof. J. A. Polson to read the paper in his absence, of which the following is an abstract:

SAFETY AND WELFARE WORK IN THE ENGINEER'S EDUCATION

By GEORGE H. FOLLOWS[1]

On March 2 of this year, at the American Museum of Safety, New York, under the auspices of the Committee on Safety Education of the National Safety Council, there was held a conference on safety education in technical schools and universities, with Mr. Albert W. Whitney, general manager of the National Workmen's Compensation Service Bureau, presiding. On March 20 a similar meeting was held in Chicago, with Mr. Whitney again the chair. At each of the meetings, a special committee was appointed to suggest ways and means of introducing definite courses of instruction in safety and welfare work in our engineering schools.

At the meeting in New York it was suggested that a corps

[1] Carnegie Institute of Technology, Pittsburgh.

Presented at the Spring Meeting, Worcester, Mass., June 4 to 7, 1918, of The American Society of Mechanical Engineers. The paper is here printed in abstract form. All papers are subject to revision.

of lecturer be chosen from among engineers of prominence in this field to visit the schools and give a series of safety talks to faculties, students and others. This suggestion was unanimously approved, but it was at the same time realized that although such a series, limited perhaps to three or four lectures at any one school, would undoubtedly arouse interest in the subject, it would not in itself constitute a definite course of instruction. To preach safety is one thing; to give efficient training in safety and welfare engineering is another. While keen interest was shown in the safety movement, the fear was rather generally expressed that it might be difficult to "find room" in any of the regular engineering courses for adequate treatment of the subject.

I was much impressed by what Mr. C. P. Tolman, chairman of the Manufacturing Committee of the National Lead Co., said at the New York meeting. In a most interesting and inspiring address he prophesied that within a very few years engineering schools would find it necessary to grant a special degree in safety and welfare engineering. He spoke of the wide field of usefulness of the safety engineer, of his value alike to employer and employee.

Practically every day since that meeting, I have been at work on a problem that the Carnegie Institute of Technology has been interested in for the past 11 years, the solution of which seems to provide the natural place for safety and welfare work in the engineering school. Our problem has been the course in commercial engineering.

I believe that in this course in commercial engineering there has been found the logical place for safety and welfare work; and this in my opinion is the crux of the problem, the realization that there is today a positive and increasing demand for a new type of engineer, and that the course of training which he must have naturally includes safety and welfare work.

The Carnegie Institute of Technology has chosen the name "Commercial" for this new type of engineer. At the outset let me say that his training must not be confused with that given in business colleges and schools of commerce; this in spite of the fact that some of the subjects handled will be found in these courses in business and commerce. The training of the commercial engineer must be based upon engineering science, economics, and psychology. Since 1907 Carnegie Tech has been giving definite courses of instruction and student work in economic production and works management, and a large proportion of the senior class in the several engineering fields has been scheduled for parts of these studies, which, however, have been specifically developed for the benefit of those graduating in commercial engineering.

If it is permissible to divide the entire range of engineering work into two main parts, the one technical, the other commercial, then the commercial engineer is the man who is trained to use or apply in a variety of ways but always efficiently what the technical engineer provides. And he is a distinct species, not a mechanical, electrical or any other kind of engineer who has in addition some other kind of general training, superficial in character, but a distinct species, whose entire college education and training are based upon the fundamentals of commercial engineering itself.

The field is broadly that of conservation, not only of materials and equipment, but of the time, the effort, the life, health and happiness of the men and women employed. There is a large and rapidly growing need for men who have been definitely trained in the direct solving of problems in this field.

Below is given the four-year schedule in commercial engineering as recently adopted by the faculty of Carnegie Tech. There was some opposition to the introduction of this as a schedule of studies leading to a bachelor of science degree in engineering, but it was finally adopted. As Mr. Whitney puts it: "Problems of industrial management are coming to be recognized as the great problems of the day." Who shall say that they may not be called engineering problems? If the designing of a milling machine is an engineering problem, surely the problems that confront, say, the efficiency man, or the safety and welfare man, are worthy of the same name! We must not forget what the word engineering means. We have no right to limit the use of it to material devices, no matter how ingenious they may be.

SCHEDULE OF COURSE IN COMMERCIAL ENGINEERING AT CARNEGIE INSTITUTE OF TECHNOLOGY

FRESHMEN

	F.	W.	S.
Mathematics	5-0	5-0	5-0
Chemistry	2-4	1-4	2-2

Buying and Selling	2-3	2-3	2-0
Industrial Corporations			3-2
Applied Psychology		2-0	1-2

In this schedule, F., W. and S. mean fall, winter and spring. The school year is divided into four quarters, with the three terms of regular scheduled work. The two-part figures, as 2-3, mean two hours of lecture or recitation and three hours of laboratory work per week.

During the past three months I have had repeated interviews with several well-known captains of industry in large engineering corporations, and they have been unanimous in

saying that today the field in commercial engineering offers greater opportunities to the young college graduate than any other single field of engineering work. One of these men put it in this way: "At present we have to take a mechanical or some other kind of engineer and instruct and train him along entirely new lines, lines of work of which he does not possess even the rudimentary fundamentals. It is a different kind of training altogether from that of the designer or strictly technical man. Men trained in the way you have outlined will be of immediate and great value to us." It is a significant fact that several of the large industrial corporations have already offered to employ our entire output of graduates in this new course.

A few years ago we experimented with what we called commercial options; and so we had electrical, civil, chemical, and mechanical commercials. We discovered that this hyphenating was inefficient. The idea itself was not unattractive to the orthodox engineering faculty, namely: that a man must be some kind of orthodox engineer first, and then if he chose he could be converted into a commercial engineer of sorts. In other words, he was to be a real engineer with the addition of commercial training.

It would be unreasonable at this time to go further into the details of the general course in commercial engineering. What I set out to show was that the course provides the logical place for safety and welfare work, and so it was necessary to give this Society a definite idea of the nature of the place that the Carnegie Institute of Technology has arranged to provide.

The commercial engineer will have to do with the solving of a great variety of problems, but there is one factor that is common to all, and that is the human factor, as dealt with through a study of psychology and its definite application in the scientific study of men, their work and their welfare.

The accompanying schedule shows that safety and welfare work has its allotted time for specific treatment, but many phases will be discussed in connection with other scheduled subjects, as psychology, economics, statistics, machinery analyses, production processes, works management, insurance, and commercial law and contracts.

It is impossible as yet to give even a synopsis of the specific course in safety and welfare work that will be given at Carnegie Tech. This will be developed during the next twelve months. There is an abundance of literature to draw upon, but the administering of specific instruction can only be developed in connection with classroom and laboratory work.

Before opening the general discussion, Professor Benjamin called on Mr. Albert W. Whitney [1] as the man largely responsible for the organization of the committees and the arrangements for the meeting.

A pamphlet had been distributed at the meeting, entitled The Teaching of Safety in Technical Schools and Universities, containing suggestions as to the incorporation of safety education in engineering curricula; subjects and speakers for safety lectures; safety exhibits, and bibliography of safety and accident prevention, etc. Mr. Whitney explained the purpose and contents of the pamphlet, saying that coincidentally with the entrance of this country into the war the arsenals and navy yards (through the assistance of the National Safety Council and the American Museum of Safety), and later the United States Shipping Board, were put upon a safety basis with well-developed safety organizations. This was not done primarily for humanitarian reasons; it was done for efficiency. It meant a saving in money, greater production, fewer wasted lives.

[1] General Manager, National Workmen's Compensation Service Bureau, New York.

The safety problem is fundamentally psychological. What needs most to be done is to make men think in terms of safety. Just as the war is introducing the idea of thrift into the nation, so the idea of thrift in the saving of lives and limbs must be learned. Safety must take its place in the consciousness of people as part of the program of conservation, and conservation as part of the program of efficiency. In no way can this result be produced in industry more effectively than by education of the coming generation of engineers.

DISCUSSION

Prof. E. F. Miller said that he had served for the State of Massachusetts in the draft of safety rules under the direction of the Board of Labor and Industry. The rules were general in nature and outlined the general methods of safeguarding —ladders, shafting, toe guards around pits, keyways, set screws, etc. There were representatives on the advisory committee of practically all of the large industries of Massachusetts, besides two insurance men. The manufacturers were inclined to feel that the insurance men were asking for so much protection that the output of the machines would be reduced, due to safeguarding. This led to an investigation in the woolen industry by the committee, and in one of the best-guarded mills of the country dangerous conditions were found, particularly in respect to belting. This disclosure brought about a more favorable attitude on the part of the manufacturer.

He said that the enforcement of these rules was left generally to the option of the Board of Labor and Industry, who would give a firm reasonable time to make the changes; but if not made, they had the power to shut down the plant. Professor Miller had served the state in an advisory capacity in cases of occupational diseases, etc., where it had been beyond the ordinary state inspector's ability to tell what to do to remedy the troubles. Some of the conditions which he found were so bad as to be almost unbelievable.

At the Massachusetts Institute of Technology instruction in safety subjects was given in connection with the course in factory construction. The protection of gears and pieces which were likely to catch a man's clothing were considered in the course in design. He felt that the reason why there had been opposition against the safety engineer was that many of the insurance inspectors who looked over risks had been so extreme in their recommendations that the manufacturers would not meet them halfway.

E. E. Clock emphasized the importance of safety devices for steam engines. To use an analogy, he said that a boiler has a safety valve and a damper regulator. The latter acts in the capacity of a governor, but it would not be safe to depend on this alone. The safety valve is essential. In the same way a steam engine is controlled by its governor, but people do not seem to realize that an automatic stop for ultimate safety is also essential.

Prof. James A. Moyer spoke on a course of study prepared for the Department of University Extension of the Board of Education in Massachusetts by experts selected by the New England Council of Industrial Safety. This course, which is adapted to correspondence methods also, is to be revised during the summer months and printed in September of this year, when it will be available for use in the state.

G. W. COON, explained that the course consisted of twelve lectures and was given to a class in Springfield, under the auspices of the New England Council of Industrial Safety, consisting of about forty-three members, drawn from the ranks of mechanics, millwrights and university graduates. There had been time for but eight of the lectures to be given, but the remaining four were to be given in the fall. The course was very successful.

CHARLES F. OAKES[1] believed that the trend of the whole discussion was toward standardization. The remarks on safety in mechanical construction were in line with a subject on which the Bureau of Standards had been working for the past four years, the standardization of safety practices. The Bureau's work in the past had been in a somewhat specialized field, electrical safety, but the success which had attended this work had moved them to broaden their scope to include industrial safety practices. This work had been initiated in the recent safety movement in Federal industrial establishments, and the movement, inaugurated in Federal arsenals and Navy Yards, had its inception at the instance of the Council of National Defense, with the assistance of the National Safety Council and the American Museum of Safety; the main idea of this was to check the number of accidents occurring in Federal plants by formulating a set of safety standards for equipment and construction. These had been submitted to the Bureau of Standards, who, working in conjunction with a committee of the Safety Engineers, had revised them, and it was expected that they would soon be adopted by the War and Navy Departments. There was little doubt, said Mr. Oakes, that a standardization of industrial safety along mechanical lines should be effected in much the same manner that the electrical industry was being safeguarded through the agency of the National Electrical Safety Code. This movement had been started in a number of states with little thought of nation-wide standardization, however, by the State Industrial Commissions. In order to coördinate the work of the states, the Bureau of Standards had been suggested as the best medium of accomplishment. In the preparation of the electrical code about two thousand conferees had been consulted and the services of over thirty technical organizations had been called upon. It had had a wide distribution, and was now incorporated in thirty two colleges in the United States. It was the intention of the Bureau of Standards, after the work had progressed to a degree sufficient to warrant it, to offer the services of its staff for lecture work among the universities as was now being done from time to time in the case of the National Electrical Safety Code.

MR. M. W. FRANKLIN[2] said that the time was not yet ripe for turning out specialists in safety engineering at the universities. A large percentage of our industries, aside from our highly-organized, large industries, had had no safety engineers. He believed, however, that the work which Mr. Whitney's committee had been carrying on in the development of specific courses in safety engineering was the most important thing yet attempted in the training of safety engineers, and would produce very concrete and immediate results. Mr. Whitney had had the forethought and the very sound judgment to choose people to assist in the work who had actual, concrete, definite experience. A course in safety engineering was necessarily so varied, so widely spread out and of such a broad nature that no one person was in a position to outline such a course. It had required the coöperation of very different persons with very different experiences to successfully formulate such a system.

Mr. De Blois, in closing, said that the Du Pont Powder Company, with between 60,000 and 75,000 employees, and whose numbers were constantly growing, would not consider the erection of a plant without first having an experienced safety engineer engaged on the work. Five years ago it was a difficult task to get a manager to realize that he needed a safety engineer. If he did get one, he didn't know what to do with him except to turn down his recommendations, but today the situation was entirely different. The company had found that it was easier to take a perfectly green engineer from the field, who had had no safety engineering whatsoever, and make a safety engineer out of him, than it was to take a man who had had five or six, or maybe ten, years' safety experience in general industries. They had secured candidates through advertising in the daily press, and from 300 applicants ten were selected for a six months' course of training. He believed that if there were available men from universities and technical schools, with the fundamentals of safety engineering and the ability to handle men, the problems which the industries were now having to face would be materially lessened.

WEDNESDAY EVENING SESSION

ADDRESSES were planned for this evening on The Procurement Program of the Government in order to present to the Society ways in which its members could best cooperate. Owing to conditions incident to the war, however, three of the speakers who had accepted were unable to attend, two of them sending their regrets on the day of the meeting. In spite of the sudden change in program, the session was entirely successful and of interest to the large audience in attendance.

PROCUREMENT OF SUPPLIES FOR THE NAVY

PAYMASTER C. E. PARSONS, U. S. N., who was one of the speakers originally invited, said that his principal reason for coming was to indicate to the members of the Society, and to the industries which they represent, the friendly feeling that the Navy entertains toward them. The big, paramount question now is that of getting material. While it has not been necessary to go outside of the Navy's own organization to provide for its increase in size, it has been necessary for both the Army and Navy to call to their aid the brains of the country in connection with material and the procurement of supplies.

Discussing some of the aspects of the procurement program, he said in part: There has been manifested the greatest interest on the part of the industries in this country toward supplying the Navy's needs. However, it is felt that even yet a greater interest can be taken, and that the Navy's business is sufficiently interesting to warrant all manufacturers attempting to get some of its contracts. Its dealings are conducted fairly and squarely, and one of its principal policies has been not only to do things right, but to do them in a way to indicate to every one that they are right.

[1] Bureau of Standards, Washington, D. C.

[2] Consulting Engineer, E. F. Fulton Co., Philadelphia, Pa.

There is no fairer basis for awarding contracts than that of competitive bidding. The Navy has held to that from the very beginning, except, of course, in those industries where the supply is not great enough to meet the demand and where it has been necessary to allocate supplies among the manufacturers, and necessary also for the Government to fix prices.

Standard specifications have been adopted, of which there are now about 1400, as a basis for equal opportunity for everyone. These are used by the railroads and by big corporations throughout the country, and even throughout the world. At the beginning of the war, owing to the changed conditions and the necessity for making prompt, immediate purchase of supplies, classified mailing lists were started. Before the war it was only necessary to advertise the Navy's requirements in order to enlist the interest of contractors and manufacturers; but now it is necessary to get into closer personal touch with them and bring to their immediate attention those things that they are in a position to supply. In order to bid on the business, therefore, it is essential that manufacturers should be on its mailing lists. It is desired that reliable firms should ask to have their names placed on these lists, and in turn it is attempted to make the lists of such a character that it is worth while for any manufacturer to have his name upon them. Brokers have been eliminated—the Navy has maintained a fight under great odds against the brokers, and has done everything possible to eliminate them in their dealings.

There have been reports among the industries relative to Government red tape, the very binding contracts, and the inspections which are so exacting, but in all cases it is believed that if any one will investigate the question fair-mindedly, he will find that these conditions are absolutely required, and particularly so for the protection of the legitimate and the honest dealer. The specifications are drawn up by the technical bureaus of the Navy Department, and these bureaus are entirely open-minded about changes in specifications. If any manufacturer thinks the material that is purchased or the specifications that we used are not proper and could be improved upon, he has only to advise the department of the fact and an investigation will be made, and in nearly every case the specifications are changed if a change is warranted. Under the present stress it may not always be possible to do this, but this is the policy of the department.

The contracts are big and the specifications voluminous, and carry provisions which often appear to the average individual when he looks them over as excessively in detail. As a matter of fact, nearly all the provisions have been brought about by efforts on the part of unfair contractors to take advantage of technicalities, which have made it necessary to set forth plainly, without a question of doubt, the provisions under which contracts are made.

As to the inspection of supplies, if an exacting inspection were not maintained and some one was permitted to furnish supplies below the standard, it would be unjust to the man who was bidding and expected to furnish just exactly what was called for, and fairly and squarely carry out his contract. Rigid inspection is essential for the protection of the honest dealer.

Very much has been said relative to Government red tape as the reason why industry has not interested itself more in the Government's requirements for supplies. As a matter of fact, red tape is simply organization and system, which must exist in an organization of the size of the Navy. But he said, "I will warrant that any chief of bureau in the Navy Department, or any official in the Navy Department, can be seen and consulted with less loss of time and with less difficulty than almost any president of a big corporation or firm. As a matter of fact, the doors are wide open, and we welcome people to come down and look us over.

"Particularly do we maintain that publicity is essential in connection with the handling of contracts. Bids are opened publicly, and people interested can be present when bids are opened and see the bids of any of their competitors. They can be assured that the awards are made fairly and squarely and that nothing is concealed."

The speaker referred to the growing tendency for Government regulation of matters connected with industry through the Fuel Administration, the War Industries Board and other agencies, and said that it was desirable for firms to have contracts either for the Army or Navy.

"We have found," he said, "even up to the present time, and it is going to be more and more so in the future, that we can be of great assistance to contractors if they have Navy contracts. We can procure fuel for them which otherwise they possibly could not get. We can arrange for transportation for the supplies which probably otherwise they could not get. We also attempt to pay promptly, and during the month of May we found that our average time for payment was only seven days after the supplies had been furnished and accepted."

In conclusion, the speaker stated that business had been placed on the east coast to such an extent, in the region north of the Potomac and east of the Alleghanies, that it would be almost impossible for more to be handled except where it was a continuation of that which contractors already had. The railroad facilities are inadequate to handle further business, and the Fuel Administration is unable to furnish the fuel for any further activities. All we can hope to do now, if we take their judgment as correct, is to maintain the present rate of production. It is necessary, therefore, to develop our great facilities in the West or in the South, in order that we may get supplies and carry on the war to a successful end.

INTERIM REMARKS

THE address by Paymaster Parsons ended the procurement part of the program, so far as Government supplies were concerned, but in respect to the procurement of speakers for the evening the work was only well begun. When word had been received that the other Government representatives could not attend, Dr. Irving G. Clark of Worcester, who had recently returned from service at the front, very generously accepted an invitation to address the meeting on his impressions and experiences abroad. Dr. Clark could not come until later in the evening and the President therefore called on some of the Society's able members to assist.

Professor Breckinridge enlivened the audience with some stories on the lighter side of university life. One of these related to a dinner which he attended, of the alumni and alumnae of a large western university, held in honor of a newly elected president of the university. Everyone was attired in evening dress except one man who sat at his right—but we will let the professor tell it:

"I didn't know who this fellow was—nice fellow, just as nice as any fellow with evening clothes on. Laughter. When the newly chosen president was called upon, to my surprise this fellow got up, and the first thing he said was: 'I perhaps ought to apologize to the ladies for appearing in these clothes, but it was this or nothing.' [Laughter.] Now, that was entirely accidental. They laughed over in this corner, and in this corner, then this corner. He tried to explain, but they

couldn't let him explain. After he got all through he sat down. 'Well,' he said, 'I did put my foot in it, didn't I? The fact was, I expected to get home and get into those other clothes, but I lost my train.' I said to him, 'I have four jokes. I bet they won't laugh at any of them as much as they did at yours.'" [Laughter.]

At the meeting on Wednesday evening Professor Breckinridge told the other four jokes, but space requires that we refer instead to a more serious note which he sounded in concluding—a clear call to the young, prospective engineers of the country. He said: "We have heard what the Navy wants in material and about certain priority of shipment and priority of fuel which may be arranged for those who are making the things that the Navy needs. But I want to call attention to one thing that needs the attention of every industry. My experience is no different from that of many professors of engineering in all of our universities. It is that we need raw material for our universities and technical schools. Never was there a time when the teacher of engineering and the teacher of science was asked day after day, in telegram after telegram, 'Where can we get a man to do this and to do that?' to say nothing of the industries that are pleading with the technical schools to send them men. There are no men. There will be no men. There ought to be some priority scheme that will put raw material into the universities, otherwise we shall have troublesome times ahead."

Past-President Worcester R. Warner followed—his remarks are reported in full. He said: "When Professor Breckinridge mentioned universities, and the study of engineering subjects, it occurred to me how important it is to start from the right standpoint. This is illustrated by a happening at a certain university, which, being a western institution, was coeducational. It was in the class of mathematics and astronomy. The class had 'Time' for its subject that morning and the professor explained the reasons for the different kinds of time—mean solar time, sidereal time and the equation of time and all the problems incident to the study of time, in astronomy. It seemed that the entire subject was covered, and, in closing, he turned to one of his students in the class and said, 'Miss Brown, what time are you most familiar with?'—thinking that she would say, as you all would, 'mean solar time,' such as we keep in our clocks and watches; but a young man right behind Miss Brown whispered loudly, so that all could hear, 'Dinner time.' [Laughter.] Of course, all the students laughed. The professor laughed, too. He didn't correct them in the slightest degree, but he said, 'Ladies and gentlemen, that all depends on the standpoint from which you look at a subject. To Newton the fall of an apple meant the great law of universal gravitation, but it meant a very different thing to the pig that came along and picked it up. [Laughter and applause.]"

Chairman George I. Rockwood, of the local committee, then made a few announcements, when Dr. Clark arrived and gave a most interesting talk, a synopsis of which is printed below:

TALK BY DR. IRVING G. CLARK

DR. CLARK spoke on conditions that he saw in France during his three years' work there with the Red Cross. Life in France, where one experiences all the realities of a country at war, presents many changes which are hard for the pre-war traveler to reconcile. Women handle the train service—which is excellent—baggage transfer, the industries, farming, hospitals, etc. The large number of soldiers in Paris and great variety of uniforms make the streets most interesting. Few people understand the significance of the many different colors and insignia, for there are Belgian, English, Canadian, French and American, and all the subdivisions and colonials of these nations are represented. The life of the city is brilliant when it is quiet on the battle fronts, but much changed. The cafés that were open formerly up to two and three o'clock in the morning, now begin to close at 9.20 and are absolutely vacated by 9.30. The theatres still run until eleven, but after that Paris is a very quiet city.

There are fewer shops and prices are very high. Food is so expensive that an ordinary meal ranges from \$1.20 to \$6 in price.

Air raids are announced by sirens like the warning New York City recently planned. Every light is instantly darkened, indoors and out, except the blue light over the *alerte* signs which show cellar refuges to which all the people in the streets immediately run. These blue lights are less visible from above than the lights of usual color. Then starts the noise of the anti-aircraft guns putting up their barrage fire. The little flashes of light from the shrapnel appear, and the lights from French planes rising in defense. Soon the roar of the falling torpedoes is heard, and all interest centers in the speculation as to whether the next one will be nearer or farther away than the last.

Dr. Clark admitted that his feelings were always uncomfortable during an air raid, for he always had to be out at this time in order to reach Red Cross headquarters. Every one seems to feel easier when under cover, even though the cover is entirely inadequate.

The concussion from a torpedo which exploded about a mile away was sufficient to spin around three times a heavy plate-glass door and to knock people out of their chairs. The weight of the bomb generally carries it through two floors, where it explodes, completely demolishing those two floors. The building below that usually stands. All windows for blocks around are blown out, and the decorated paper pasted in to replace the glass presents an extraordinary sight.

The French are unable to joke about the air raids as they do about the "Big Bertha." The defense from aeroplanes is now much more effective than at first so that the enemy planes do not reach the city very often. Some new method of protection seems to have been used which apparently is a military secret, and very successful.

Air raids last from 40 minutes to 3½ hours, and at the close a welcome bugle announces that the danger is over.

The French make a little party of the periods spent in the cellar refuges, where they play cards, have music and enjoy meeting the new people who are obliged to seek shelter in that locality.

Dr. Clark spoke enthusiastically of the methodical way in which an immense amount of hospital work is turned off. The team work is splendid, no hurrying, but brisk, steady work. He found the morale of the men in the hospitals wonderful, and referred particularly to the work of two American physicians as an example of the loyalty and devotion which everywhere exists. They were operating in a French hospital, but under the direction of the American Red Cross. When the Germans were advancing the French were ordered to evacuate, but some of the patients were so badly wounded they could not be moved. The Americans, not being subject to French orders, decided to remain. Refugees and wounded came pouring in and the two American surgeons operated all day and all night and part of the next day until it was established that the French line was holding and the French were ordered back.

EMERGENCY TECHNICAL WAR TRAINING

The War a Matter of Matériel and Technically Trained Specialists. The Problem is That of "Re-educating an Entire Nation for a New Kind of War"

THE session devoted to Emergency Technical War Training, held on Thursday morning, June 6, in the lecture room of the Electrical Engineering Laboratories of Worcester Polytechnic Institute, was one of far-reaching importance. Inasmuch as the great need for technically trained men is constantly becoming more and more acute, it is vital that a comprehensive scheme for such training be speedily put into practice. The fact that considerable has already been done in this direction merely tends to emphasize how much has to be accomplished. For this reason Major James E. Cassidy, of the 301st Engineers, and an official observer at the French front in 1916, was invited to open the program by outlining the enormous scope of military activities dependent upon technically trained men. Professor Arthur L. Williston then spoke on the problem from the point of view of a director of vocational training. Lieutenant André Morize, detailed to the Department of Military Science at Harvard University, summed up the remarks made by the previous speakers in an inspiring address.

Following, Mrs. Frank B. Gilbreth, in the absence of her husband, Major Gilbreth, made a plea for an increased enrollment in technical schools and colleges. Motion pictures were then shown descriptive of the Browning machine gun, its operation and method of clearing, etc.

Mr. John R. Freeman, Past-President of the Society, took advantage of the presence of the motion-picture apparatus to show by this means a method he had employed in demolishing a smokestack, and the accuracy with which the stack was made to fall was demonstrated in a most interesting manner.

Vice-President Charles H. Benjamin presided, and a very attentive and enthusiastic group of members and guests profited by the remarks of the speakers. The following report is an abstract of the proceedings.

CONDITIONS AND REQUIREMENTS OF WARFARE

By MAJOR JAMES E. CASSIDY[1]

THE complexity of modern warfare has brought the engineer into a position that was never before occupied in the course of war. At the outbreak of the present struggle neither the Allied nor the Teutonic armies really realized what the war was coming to as regards the methods of fighting. Practically all previous methods of fighting have been relegated to the scrap heap to a certain extent. We saw for the first few weeks of the war a war of movement, where bodies of troops were engaged in maneuvering for positions and fighting in the open. Following the battle of the Marne, however, where the Germans were thrown back to the Aisne River, the war lapsed into a war of positions.

When the war of movement ceased and the war of positions began, then it became a matter of *matériel*, a term that the French coined to cover all the equipment and the appurtenances of war. The development of the war of position rapidly made the artillery—the mechanics of war—a very prominent feature, and also started the use of the airplane. Up to this time the airplane was considered nearly as dangerous to our own men as to the opposing forces. As an example of the trend of warfare, the grewsome works at Namur, Liège, Antwerp, Maubeuge, etc., were built to withstand a 6-in. artillery fire, which was considered the heaviest artillery that an army in the field could carry to any advantage. However, when the infantry failed to take Liège by storm they brought up Austrian 9- and 11-in. howitzers. There has been a great deal of newspaper comment on the work that the "Busy Bertha" and the 42-cm. howitzer were supposed to have done. As a matter of fact, it was not those guns that were used, but a size between those and the 6-in. guns, and the 9 and 11-in. howitzers that are believed to have destroyed the forts mentioned.

The War a Matter of Matériel

One of the best axioms or most emphatic axioms of this war is that men cannot combat matériel. You must destroy matériel with matériel before men can advance, before positions can be taken. The side that produces the greatest destruction of matériel is the side that is going to win the war.

To a certain extent up to the present time there has been more or less of a deadlock. The airplane situation is practically in that condition. For certain short periods one side has been able to overcome the matériel of the other, but on the whole there has been almost a stand-off. For this reason the war of movement has entirely ceased; the war of positions is on.

In former wars, if one combatant could maneuver around and capture the capital city of the other and get a good slice of his territory, peace was declared. In this war territory means practically nothing. The function of the army of today that wins consists of three things: the destruction of men, matériel and morale. The destruction of matériel is the prime factor in the destruction of men, and the destruction of men means the destruction of morale. We have seen it in various fightings; for instance, where the Germans hurled their masses on the French positions and were simply slaughtered. The same thing occurred in the first and second battles of Ypres in 1914. The same thing has been occurring in France and Belgium in the last few weeks of fighting. The price the Germans have paid for a few square miles of territory has been entirely out of proportion to the advantage gained. Their reserves and the disposition of their forces are necessarily limited, and when their reserves are wasted they have nothing further to draw upon. Their only hope, as a wild gambler's chance, was to do something big, but the British, French, Portuguese, Americans, and other men that have taken part in this fight have tended to destroy that one gambler's chance, and as time progresses it will be completely destroyed. The slaughter of men—the Germans fighting *en masse*—the slaughter of men who are forced to move forward under the murderous fire of machine guns and rapid-fire artillery, undoubtedly has its effect on the morale of the soldiers and is bound to tell in time.

The part that we can play in this war and will play is a very great one. By superhuman efforts on each side there is now a certain amount of deadlock in the situation. In the air the Allies have maintained a small supremacy. They have the speed and the maneuvering ability and, on the average,

[1] 301st Engineers, Camp Devens, Ayer, Mass.

they have the better class of fighters—they are airplane fighters. But on the whole it has been to a certain extent a stand-off. We are coming in with fresh forces and unlimited reserves, and while we were laggards for three or four years we have made great strides the last fourteen months.

In a lecture yesterday morning, Colonel Paul Azan, chief French military attaché in this country, mentioned the need for a lighter mobile field gun than is at present in use. We have the 75, which is practically the 3-in. gun; then the next step down the line is the 37-mm. gun, which is a very effective gun but only fires a 1-lb. shell. If the mechanical engineers in this country can produce a gun somewhere between those two, say, one of $2\frac{3}{4}$-in. caliber and much lighter in weight, they will be doing an enormous service toward ending the war. Colonel Azan has gone all over this country in connection with military work and says that he never fails to speak of this when he is addressing any body of men, whether soldiers or whether civilian societies, in the hope that some one will take the idea and work on it.

THE PART PLAYED BY ENGINEERS IN THE WAR

The question, then, outside of the production of matériel for the armies, comes down to the part the engineer is playing in this war. Well, it is no small one. The corps of engineers in this country at the outbreak of the war consisted of 200 officers and 2100 enlisted men. Our organization today consists of 252 regiments and about 108,000 men and 7000 officers. For fourteen months that is not bad, and our proportion is increasing all along. In the time at my disposal I can merely mention the different activities in our Army that have been turned over to the engineers.

For instance, we have the work of mining and sapping; the various classes of bridge work—pontoon and other classes used in the field; and the mining of deep gallery shelters, a very important feature on the fighting fronts of today in the war of positions. For several miles from the front lines all the soldiers live in deep gallery shelters. With the modern high-angle artillery fire one is not perfectly safe in a deep gallery shelter unless he has from 25 to 30 ft. of roof over his head. Major Rousseau of the French engineers, in commenting on that point, stated that often a mistake was made in constructing a machine-gun shelter with only 4 or 5 ft. of earth overhead, and said that a piece of sheet iron would serve equally as well, because neither would turn even the smallest shells.

The work of demolition and the defense against the poisonous gas used by the Germans has been turned over to our engineer service. Then we have the searchlight service and camouflage paint service. We have not progressed so very far in tanks yet, but have a tank corps organized and tanks under construction or under contract. We have a railway transportation regiment which has been turned into a corps, and the gas and flame offensive service. Then we have the map section of the engineers and quarry regiments to quarry and crush stone for road work. One of the primary things of the war today is getting up supplies; and the building of railroads and ordinary highways has involved figures that are staggering to the ordinary individual. Then there are tunnel companies for various kinds of tunnel work, mostly back in the zone of the interior.

CANTONMENT CONSTRUCTION ABROAD

With reference to cantonment construction abroad, I would say that most of our troops are billeted in France. For instance, a certain village will have every house and every barn marked with the number of men it will accommodate and the town major has a complete list of every house, knows exactly where he can have his headquarters and knows how many a certain building will shelter. I believe the usual basis of figuring that billeting is about seven soldiers to one civilian inhabitant. In our training areas back behind the lines, however, we build cantonments differently from what we do in this country. Here we have simply let contracts for the erection of buildings; for use abroad we have furnished portable, or rather, sectional, houses. The original design was for houses 20 ft. wide and 237 ft. long. The doors were put on a panel, the windows were put in and the roof was in sections. The only thing not built up here was the floors. The work was parceled out to 15 mills and enough of these buildings were completed in 60 days to house 500,000 troops. So far as I know, that system has been continued.

The large army of today not only needs plenty of food supplies and ammunition but it needs water as well. So we find the Germans poisoning wells and dropping in bodies of animals and men or anything to destroy the value of the water for immediate use, making it necessary for the engineers to plan for a water supply to follow the armies, run pipe lines up, dig wells, and take steps for purifying water. Then we have our general construction units which do all sorts of general construction work back in the zone of the interior. We have the general repair shops and supplies. We have railway-construction regiments. There is one particular regiment—the 23d Engineers—that is organized for highway work and will ultimately have under its direction an immense force of German prisoners.

I happened to have one of the battalions of this regiment under my charge for tactical instruction at Washington barracks last December, and an amusing incident occurred in connection with the Second Liberty Loan. One of the enlisted men went around to men in his regiment asking for subscriptions to the Liberty Loan, and he came to one man, a private, and asked him if he didn't want to subscribe. He said he believed he did. "How much shall I put you down for?" said the solicitor. "I will take $100,000 worth," said the private. The soldier thought that was a great joke and rather laughed, but the private told him, "If you don't think that that is all right you can wire ——," naming a certain bank in Pittsburgh. The soldier reported the conversation to his superior officer, and the officer said, "All right, just wire this bank for curiosity." The answer came back, saying that if this man wanted to take $5,000,000 worth of Liberty Bonds he was perfectly good for them. [Laughter.] That is a little illustration of the cosmopolitan composition of this regiment. In it there are men serving as privates who have had 10 or 15 years' engineering experience, consulting engineers, some of them. You will find there almost every class.

Then our railway engineering corps is very elaborate. We have the standard-gage construction and operation men. We have the 60-cm. units and the 40-cm. The 40-cm. are light railways that are built up in the trench lines, leading up to the front lines, and the 60-cm. are back of them. The 40-cm. lines are entirely for small cars moved by hand. The 60-cm. cars are partly horse-drawn and partly drawn by small locomotives, either gas or steam. We have sent over a great number of cars and engines. Our equipment in this country is very much heavier than the standard equipment in Europe, and where we can use our engines and cars without going

through tunnels, we send our equipment. Then to keep up this railway work we have our railway shop regiments, of which there are quite a number. Then of course we have field fortification and fortification in general, and recently aerial photography has been turned over to the engineers. It seems that when they run into anything that nobody else wants particularly they immediately put it on the engineers!

Taking of Messines Ridge by Engineers

Any one of these different items is a story within itself. In regard to some of them I probably could spend an hour talking on one particular feature, but I want to mention a few things that have come under the scope of the engineers, for instance, in taking Messines Ridge. There has not been a great deal published on the actual details of taking Messines Ridge, but for 16 months previous to the taking of this ridge by the British and Canadians they were very busy tunneling this hill. It was a point the French and British had fought over in the early days of the war; in fact it had been retaken once or twice for short periods as the tide of battle swung back and forth. It was a ridge that overlooked the British lines and was rather a thorn in the side. For 14 months before this attack was made the British were busily engaged tunneling this hill, running mine galleries. There were 24 of these mine galleries and their average length was over two miles. These galleries were about 4 ft. by 6 ft. and as the earth had to be carried out and disposed of so that the Germans would not know any more about what was being done than possible, it was quite a tedious task. The Germans knew that the British were mining this hill, although they could not tell where. Owing to the geological conditions of this particular terrain there was a stratum of clay above the British tunnels acting as a muffler, and while the Germans could tell by the sounds that there was mining going on, they were not successful in doing any countermining. The idea is that when any one is running a mine gallery up to your trenches, you should countermine and blow him out with what is known as a counterflame, that is, a small shaft that runs into his mine. The British played a little joke on the Germans. The Germans were holding Messines Ridge as lightly as possible, knowing that tunneling was going on, but not being able to locate the mine galleries. These mine galleries were eventually finished and branched out in different directions under the German lines, and a million pounds of aminol was placed in them. This aminol, which is very much of the same nature as our TNT, was put into rubber bags and these bags were placed about four months before they were detonated. The British played their little trick by placing their mines and then waiting for an opportune time, because the Germans, after the British stopped digging, got over their scare. It is rather trying on the nerves to know that some one is mining under you and you are unable to find him—it shakes the morale of the best troops. So there was a period of about four months that they waited after the mines were laid and the Germans had gotten over their nervousness and Messines Ridge was held very strongly. Then one morning, at exactly four o'clock—and I might say in this connection that very great care is always taken in any sort of movement to see that all watches are absolutely synchronous; every watch must be exactly with the others, there must not be thirty seconds' difference—the million pounds of aminol was exploded and every gun on the British side started firing. The whole top of Messines Ridge was practically blown off, and the country seemed to rock for about ten minutes. The British troops moved forward without very many casualties. The Germans were simply stunned by the artillery fire and the explosion of those mines. Following the explosion of the mines a novelty was introduced in the way of machine-gun barrage, the Royal Engineers having placed machine guns about 1800 yd. behind the British positions.

The Italians performed a similar feat in the Col di Luna in the Dolomite Alps. Those peaks are very jagged and the Austrians held a post on a small peak that the Italians could not get at. On January 16, 1916, they had prepared to go after this peak and they moved in compressed-air and other necessary machinery under the shelter of a ledge, some 4000 ft. below the Austrians who were up on the top of this peak. They started their tunnel, ran it up at an angle of 45 deg. for about 4000 ft. to get under the Austrian position and spread out in a sort of fan shape and placed 95 tons of aminol under this position. On July 16 they exploded the charge and there was nothing left of the Austrian position, not even the top of the peak. The whole top of the mountain was removed.

These are but isolated incidents out of thousands. I am sorry I have not the time to describe the engineer's progress from the time he arrives at a port in France and show what he does up through the lines and up through the entire country. This it was my original idea to do, but I have just mentioned these few little instances.

SPECIALIZED TRAINING OF TECHNICIANS

By ARTHUR L. WILLISTON

I APPEAR here on this program this morning in a dual capacity: First, as the chairman of a committee of our own Society which was appointed shortly after the January meeting to see if through the agencies of the Society work might be stimulated to increase the number of men in the United States who had some kind of specialized ability of one sort or another that might be useful in connection with this gigantic task in dealing with the matériel which Major Cassidy has just told you about; and, secondly, I am here as representative of the Committee on Education and Special Training created within the War Department by special order of the President through Secretary Baker on February 10, which created within the War Department this special organization charged with very wide responsibility and duties in connection with the development of specialized technical skill in the shortest possible length of time—intensive war training of technical or artisan character.

The War's Demand on the Engineer

Major Cassidy has pointed out with emphasis and clearness the remarkable way in which this war differs from all other wars and the supreme way in which matériel of extraordinarily varied and complicated character enters into it from start to finish—absolutely through every part of the work. We on this side of the water are more or less thrilled by the wonderful exploits of airplane, of submarine, of wireless and one and another of the very recent and startling advances in applied science. We often fail to realize, I think, the extent to which gigantic engineering problems calling for exactly the same kind of intelligence and accurate planning and skilful application and unusual skill or technical abilities enter into the handling of all the mass of matériel. The question is not one of dealing necessarily with these unusual

factors so much as it is the kinds of big engineering propositions that this country used to think of in connection with our great industries. It is a problem of transferring, transplanting a certain number of thousands of tons of iron and thousands of tons of steel or gas or inflammable material or some other necessary factor in the situation from one place to another with precision, on time, with the least possible effort and with the maximum effectiveness—the same kind of problem that the United States Steel Company has to meet in Pittsburgh. And it calls in an extraordinary degree not only for the engineer who plans at the top but for the whole personnel, all the way down the line from commanding general to rear-rank private, for the same kind of organization, the same kind of ability to do the particular job at the right time in the right way that great industries in America or great engineering enterprises of one sort and another call for.

Urgent Need of Additional Shipping

The difficulty in transporting troops on account of lack of ships from this side of the Atlantic to France increases tremendously the need for giving every possible particle of training that can be given on this side of the water so that the men may be prepared to be effective at the earliest hour after they arrive on French soil. We fail to realize some of these things, I think, to understand that the preparations for increasing the Hog Island plant last winter were going on at the rate of approximately four times the maximum rate of construction of the Panama Canal at any time, and that similar increases in shipbuilding plants throughout the country totaled possibly thirty times the Panama Canal so far as one can contrast one method of construction with another.

The Special Obligation of the Society

I am saying this simply because I wish to get The American Society of Mechanical Engineers and its entire membership to appreciate that we need not engineers alone but we need a supply of technicians, of new kinds of artisans all along the line. And there is not in existence the supply. President Wilson might have said when he described this war, "It was a problem of reëducating an entire nation for a new kind of war." No body of men in America can understand the nature of the problem so well as the members of The American Society of Mechanical Engineers, I think. And on them, because of that ability to appreciate, is a special obligation to come forward and exert in every possible way a public sentiment which will help this work forward as nothing else can.

THE NEED FOR SPECIALISTS IN THE PRESENT WAR

By LIEUTENANT ANDRÉ MORIZE[1]

As Major Cassidy, a few moments ago pointed out, the warfare of today presents a new character, being a war of fortified positions. This means that we have to abandon completely the words and the idea of field warfare or open warfare. These words have not meant anything since the battle of the Marne, since September 1914, when the two armies began to dig themselves in and to organize the long lines of fortified positions which run from the North Sea down to the Swiss border. It does not mean that the fighting will be confined to the trenches, but it means that after all the battles the armies will find themselves again in fortified positions, organized lines of trenches, defensive organizations, and that the fighting on the open ground will be limited always to the pursuit of the hostile forces from one fortified position to the next fortified position. And when it shall happen that the army which is attacking does not find the hostile army fixed on an organized position, after a few days, the war will be over in less than a week.

The Need for Technical Training

What does that mean now? After the first blow the Germans were able to get through the first line, through the second line, possibly through the third line of Allied positions, but now they find again the French and British and American troops established on fortified positions hastily dug during the first day but improved day after day, hour after hour. And now they have to start again in the same manner, march to the new position—the attack of a fortified position, and it is absolutely wrong to oppose the two terms of trench warfare and open warfare. It is very important for the right direction of training to realize the new characteristics of the war of positions. And the point I wish now to emphasize is that, given the new character of the war of today, the men—more than the men, the officers—are perfectly useless if they have not had a complete technical training. Why? First, because the war now is a war of specialists. And all the men engaged in the present war must be specialists because the old conditions of the fighting are all gone, and to reach the enemy sheltered in fortified positions, using heavy artillery and new weapons such as gases and flames—as well for the attack as for the defense, it is necessary to have men with special training and technical training.

The rifle and the bayonet, the weapons of the old-time fighter, are still useful, and it is wrong to believe that the French and the British are going to abandon them more or less—not at all. Our men are trained in the use of the rifle and the bayonet, but the rifle is useful only in special cases when we can fight on open ground between two positions, and the rifle and the bayonet are absolutely powerless against men sheltered in deep trenches and in dugouts. So our men, the plain infantrymen, must be trained in the use of all the new weapons—grenades, bombs, smoke bombs, incendiary bombs—and in the use of the trench mortars. Besides the infantrymen we have the men trained for gas warfare, for liquid-flame warfare, and finally we have all the new kinds of weapons which under the name of "tanks" are nothing but assault artillery, artillery used in close coöperation with infantry, advancing with the attacking lines and sometimes preceding them.

The War One of Specialists

I cannot give more details about these different lines, but it will be seen that the war is now fought entirely by specialists and that these specialists must get a technical training. It is impossible to improvise in a few days a man for a gas attack. It is impossible to improvise in a few days the man to use bombs and hand grenades in a satisfactory way. We need men and officers with technical training.

A second reason which makes technical training more and more necessary is the fact that the present war is a war of close coöperation between the different arms of the service. If we think of all former wars it is easy to realize that

[1] French Military Mission, Northern District; detailed to Department of Military Science and Tactics, Harvard University

infantry had to play the most important part—and sometimes alone—helped by artillery, but it was possible to think of infantry fighting, pure infantry fighting. Aviation was unknown. Engineers had to play but a small part. The supply service, the railroad service, were useful, but not as necessary as they are now. If we now think of the conditions of a large battle—one in which all the resources of the two armies are engaged—it is easy to see that the battle is the common task of all the branches of the service, as any one of the different branches, infantry, artillery, aviation, working alone is helpless. Even for an operation like the capture of a few miles of hostile positions all the arms of the service must work at the same time, and now all the branches of the service need men with technical and complete training.

Training in Use of New Weapons Necessary

In the infantry all the men must be more or less specialized in one of the new weapons now used—grenades, trench mortars, machine rifles, machine guns, etc. In the artillery the conditions of the work are now quite different from what they once were. The old idea of the artilleryman was a man with a technical knowledge of the gun and its different parts, and familiar with its tactical use. But now artillery work means, first, the technical knowledge of the science of adjusting fire with the long-range guns and with the difficult task of adjusting fire at small targets, sometimes very well camouflaged; second, technical knowledge of the science of locating, of spotting the hostile battery. That is a complete organization now. We have two such large organizations that started in the French army under the names of *sections de repérage par le son* and *sections de repérage par les lueurs*. These mean spotting the hostile batteries, first, by observing the sound, and, second, spotting them by the flash of the battle. They are complete scientific organizations with special officers, and they play a very important part in all the operations now. When it is realized that it is impossible to launch an offensive today without first silencing and neutralizing all the hostile batteries, it is easy to realize the importance of the rôle played by the men who have to locate the hostile batteries by their technical knowledge.

Third, technical knowledge of topography. The topographic work is a part of the artillery work because, given the long range of the guns, the use of the ground to conceal the batteries behind the hills and the contour of the ground, most of the adjusting work is done entirely with the map; and so the necessity of making, drawing and reading maps—technical knowledge for artillery work.

Fourth, the batteries are exposed to hostile fire, so the first condition to be able to destroy the hostile position is to have a good protection for our own batteries, and the technical knowledge necessary to build the batteries and emplacements—to know exactly the conditions of resistance of materials, to know how to use the ground, and the different kinds of supplies to protect the batteries as much as possible—technical knowledge necessary for such a job.

Question of Artillery Transportation Most Important

Very probably the most important point now is the question of transportation of artillery. If the Germans, as Major Cassidy pointed out, have been able to advance so fast in the last few weeks it is because they have been able to find new methods of transportation for artillery. All the preceding drives have been more or less limited to the range of the long guns—six, seven or eight miles. The depth of the German advance is now much greater and wider only because they have been able, thanks to their technical ability, to find more efficient means of transportation for artillery. The question of the transportation of artillery material, and especially of heavy guns and heavy ammunition, is one of the most important problems of today. So you see that relating to artillery alone at least five points require technical knowledge.

I will not speak about aviation; aviation is nothing but a technical branch of the service. But just one word about the connection between all the different branches of the service. Each of them needs a technical training. But to connect them, to have them work together, to realize what we call the *liaison* between the different arms of the service, we need more than ever men with technical knowledge. Liaison between the different arms, between infantry, artillery and aviation—the liaison between the different units and the high command—means organization of telegraphs, of telephones, of wireless, of ground telephone, ground telegraph and visual signaling, searchlights, etc. For all these different means of liaison we need men with technical ability and technical training.

And finally, Major Cassidy emphasized the point that the present war is a war of matériel and of supply. It means the question of production in this country, the question of transportation of troops, men, food, supplies, equipment and everything; and the question of distribution of the supply of the ammunition at the front. It means, as he said, the organization of an extensive network of railroads, regular and field, depots, stations, etc. So you see a war of positions, a war of specialists, a war of coöperation between the different arms of the service, a war of matériel and of supply. From all these different points of view the war is now of such kind that all the men engaged must have a complete technical education and training. And not only the men engaged in the special technical lines, but even the most modest infantry officer; a second lieutenant now, leading the platoon, must be able to know about liaison of the telegraph, telephone, about the digging of a dugout, about the organization of a drainage, etc. Technical education is accordingly of first importance and it is the duty of all to help those directly engaged in military training to make the country realize these new characteristics of the war. The war will not be won by men with rifles and bayonets. It will be won by the effort the whole country will make in order to meet the requirements of the new kind of warfare we have—the war of matériel, the war of supply, and the war of technical knowledge.

JOHN R. FREEMAN, during the session, had projected on the screen a short film showing a method he had used in demolishing an abandoned factory chimney. The chimney was a radial brick stack 160 ft. in height. The work was accomplished in the short space of four hours' time. The method shown consisted in digging a hole in one side of the chimney, in which a cobhouse blocking of hard pine was then loosely built. The weight at first was all taken at the point where digging was started, and the question of having the chimney fall in the direction desired was one of tearing bricks out from each side of the starting point an equal distance at a time. The wood blocking was then saturated with oil and set on fire, and when sufficiently consumed, the chimney fell on the side from which the bricks had been removed.

In falling, the chimney came within two feet of centering on the spot selected in advance, demonstrating the precision with which the method can be worked.

SECOND GENERAL SESSION

THE second General Session was held on Thursday morning, June 6, in the Mechanical Engineering Building of the Worcester Polytechnic Institute, and, considering that the session was held simultaneously with two other attractive sessions, it was well attended and a lively interest was manifested in the five papers presented for discussion.' President Main presided for the first half of the session, when he turned the meeting over to Vice-President Greene, who concluded it.

The six papers, in the order of presentation, were: Efficiency of Gear Drives, by C. M. Allen and F. W. Roys; A Self-Adjusting Spring Thrust Bearing, by H. G. Reist; Air Propulsion, by Morgan Brooks; Electric Heating in Molds, by Harold E. White; The Elastic Indentation of Steel Balls Under Pressure, by C. A. Briggs, W. C. Chapin and H. G. Heil; and Stresses in Machines When Starting and Stopping, by F. Hymans (by title only).

Although the subjects of the papers were so varied, participation in the oral discussion was general, and the proceedings of the session, with the large number of written discussions contributed, were somewhat voluminous.

Professor Allen presented the first paper, which described an apparatus, set up in the laboratory of the Institute and on view before the session, for measuring the efficiency of gear drives by measuring directly the power loss through them. An electric motor is so hung in a cradle that both its armature and field are free to turn. The armature shaft is connected directly to the pinion gear shaft and the driven shaft directly to an Alden absorption dynamometer. The reaction of the motor field is balanced by the action of the absorption dynamometer through a simple lever. The arms of the lever are accurately proportioned to the ratio of the gears.

The paper illustrated methods of calculation and gave data of efficiency tests of both worm- and bevel-gear drives.

President Main, H. G. Reist, Prof. W. H. Kenerson, Prof. A. A. Adler, R. G. Nye and Prof. W. W. Bird discussed the paper. The trend of the discussion was that the results given should be somewhat discounted, to which Professor Allen replied that the paper had been written simply for the purpose of presenting a method by which any one could test gears and get results without much trouble; he thought that some other agency than the Institute should be prevailed upon to carry out reliable experiments, having the method provided.

Mr. Reist's paper, presented by the author, illustrated spring-thrust bearings for vertical water-wheel driven generators, to carry a load of 300,000 lb. at 100 r.p.m., cited allowable unit pressures, and described the construction of the bearings. In these bearings one of the surfaces is made to yield at any point by using a comparatively thin plate supported by a large number of springs. The pressure usually allowed is 300 to 400 lb. per sq. in., the design permitting a very thin oil film without metallic contact.

Professor Adler opened up a discussion by calling attention to some of the steps in the history of bearing theory, which he promised to write up in mathematical shape later. He then asked the author some questions regarding film lubrication and also alignment.

C. A. Briggs said he had seen the bearing under test at Schenectady and it had impressed him favorably.

Professor Adler continued with questions, mostly for information, and Mr. Reist answered them in turn.

Professor Brooks then presented his paper, describing experiments to show that the screw theory for propellers should be replaced by the theory of reflection or batting action. By means of two electric fans and an anemometer he demonstrated how air can be driven by a propeller at a velocity nearly twice as great as the product of the pitch and the revolutions. He said he knew the idea would be received with skepticism, but he would welcome suggestions regarding its explanation and proof.

As was anticipated, both the written and oral discussions were lively, some discussers receiving the paper with enthusiasm and some contradicting the author's conclusions entirely. The terms "sustentation," "superspeed," "vortex," "stream line," etc., were frequently cited; and, in fact, before the discussion was over all the nine theories of propeller action had been brought up.

Those contributing to the discussion were N. W. Akimoff, H. G. Reist, W. C. Durfee, C. W. Howell, G. D. Bothezat, H. F. Hagen and C. A. Briggs, and justice can only be done to their remarks by printing them in full later.

Mr. Briggs then read his paper on indentation, which described experiments carried out at the Bureau of Standards showing that the indentation of balls pressing against flat surfaces was not directly proportional to the pressure but to the two-thirds power of the pressure. These experiments were developed in connection with the adjustment and standardization of precision apparatus incidental to the manufacture of munitions gages.

The discussion of this paper was light, questioning the author on the materials, shapes of surfaces and pressures which he used and those which his results could be extended to apply to.

Mr. Harold E. White presented the next paper, which he said was a practical paper, illustrating a mechanical engineer's method of utilizing induced electric currents and hysteresis losses in solid iron to heat molds, the method being one which electrical engineers instinctively turn away from, as they usually laminate every magnetic circuit they possibly can.

Though the interest in the topic was not large, the paper was well received, and the author was asked a number of questions by Mr. W. H. Marshall which excited the interest of those present.

Mr. Marshall's main requests were in regard to the practicability of melting glass in molds heated as the author described. Mr. White thought this, on the whole, impracticable.

The last paper scheduled was a mathematical paper by Mr. F. Hymans, giving a new method for the correct evaluation of the forces acting on machine parts during start or stop. The method was illustrated by application to a vertical geared hydraulic hoisting machine.

There were no oral discussions of this paper, but written discussions were sent in by N. W. Akimoff and Prof. S. E. Slocum. These will be printed in full later.

Mr. Akimoff eulogized the paper, saying that no true engineer could help feeling a better man for having studied it. It was not difficult and was very clearly written. He entered a plea for more members of the Society to interest themselves in the finer points of this character.

Professor Slocum was of the opinion that the author's application would apparently afford a considerable refinement in the calculation of stresses of machine parts. He thought the author's use of the unfamiliar normal coördinates, while it served to show the generality of the method, complicated the solution somewhat, but he did not offer this as a criticism.

There being no further discussion, the meeting adjourned.

EMPLOYEES SERVICE SESSION

Thursday Afternoon Meeting at the Norton Company's Plant for the Discussion of Industrial Housing and Other Requirements for the Welfare of Employees

A PROFESSIONAL session of exceeding interest, at which employment methods, labor turnover, and welfare measures for promoting and conserving the health of employees were among the subjects considered, was held in the administration building of the Norton Companies' plants at 2.15 p. m., Thursday, June 6, Past-President James Hartness acting as chairman. Four papers were presented at this session, the first two dealing with the important subject of housing conditions.

The Workman's Home and Its Influence upon Production in the Factory and Labor Turnover, Leslie H. Allen.

Indian Hill: An Industrial Village Created by the Norton Company, Clifford S. Anderson.

Employment Methods as Followed by the Norton Companies, E. H. Fish.

Vestibule Schools, J. C. Spence.

Mr. Allen's paper was published in the June issue of The Journal; the texts of the others immediately follow in slightly condensed form.

INDIAN HILL: A MODEL INDUSTRIAL VILLAGE

By CLIFFORD S. ANDERSON,[1] WORCESTER, MASS.

UP to the present, the Norton Company has not been called upon to meet and solve the industrial housing problem as it is generally understood. Many concerns which have been located in the smaller towns, in order to provide homes for their workmen have had to practically create a local village. Other industrial plants situated in large cities have felt it imperative to bring about an improvement of home conditions for employees previously living in slums. We have fortunately been situated on the outskirts of an industrial city to which laborers are constantly attracted. It is a city which up to the present time has no slums. As a matter of fact, our lower-paid employees are able to secure living accommodations that are safe and light and well ventilated, and as clean as the occupants are inclined to maintain them, at a price commensurate with their income, more readily than any group of our workmen. Accordingly, we have not set out to approach the problem from the bottom but rather from the top. Our aim has been to make it easy for our foremen and more progressive workmen to obtain for themselves homes of taste and convenience, likely to make the employee happy and contented with his personal work, to improve his taste, stimulate his ambition, lead him to assume without terror some of the responsibilities which fall upon men of all stations in life, and to furnish for the other employees tangible evidence of the thoroughly satisfactory and worth-while things of life which may be secured by diligence and industry, and so stimulate in them a desire to make themselves more useful, to improve their conditions of living, and to so win for themselves and for their families a bigger share of the truly good things of life.

The Norton Company has embarked on this work, not solely with the idea of indulging in philanthropy, but from the point of view of enlightened self-interest, considering the return in loyalty and intelligent labor, and the probably increasing values which are likely to result from the development of the Indian Hill community. We have given our workmen nothing but an opportunity. The land cost them all that it cost us. The houses erected thereon cost them all that they cost us. We have simply furnished them the opportunity to buy a home not only on easy payments but at cost, an opportunity which is not elsewhere extended to them. The Indian Hill community is a corporation, the stock of which is held by the Norton Company, and was brought into being merely to handle more easily the work of creating an industrial village. The policy of its board of directors, which is identical with the directorate of the Norton Company, is to administer its affairs without profit and without loss; all of its activities are purely business, its purpose, to insure to our workmen the opportunity of an attractive home at cost, without exacting a penny for the profit of others, and to insure to the stockholders, in other words, the Norton Company, the business-like execution of this mission without a penny of loss.

When the village was originally opened in 1915, there were, of course, many who rushed in to avail themselves of the new opportunity, but there are residents on the hill who have been invited to come there by the company, families whom we felt would be leaders in the community, and contribute to the success of the village life. We have not hesitated to suggest to certain employees that they undertake a considerable financial responsibility in securing a home in this way, for we have found from experience that the appreciation of these opportunities up to a certain point is in direct proportion to the sacrifices that are required in order to enjoy them. Yet I do not think that in any case periodical payments are being made upon a house in excess of 25 per cent of the income of the residents.

In starting out upon our program we were fortunate in having right at the very doors of our works an ideal site—a beautiful hillside overlooking the waters of Indian Lake, with an opportunity for gentle grades and slopes for the roads which have been availed of to the greatest extent by the architect, Mr. Grosvenor Atterbury, of New York, whose services we sought because of his similar work in connection with the Russell Sage Foundation and their housing problem. The idea was to establish here homes which should be substantial, resistant to fire, would not require a large cost of maintenance and which would combine taste with efficient relation to the need of the class of workmen who were likely to reside therein.

In the very first instance the company decided that the relation of employer and employee was sufficiently intricate so that we did not want to assume also that rather difficult relation of landlord and tenant. Consequently none of our houses are rented; all are sold. We were fortunate in securing the land at a low price and offered it to our workmen at the actual cost per foot, including the improvements, and built the houses for them through our own hired contractor. There are five or six different styles of houses so that that unwholesome uniformity that used to dominate an industrial village is presently lacking.

The question came at once, how should we finance our scheme? We decided that we would sell direct, giving a full

[1] The Norton Company.

title to the buyer, taking back a mortgage. We require of the purchaser an initial payment of 10 per cent of the cost of the house. He gives us in addition a time note for 12 years and a demand note. These are secured by a mortgage to the company. We require of him also that he take out a certain number of shares in a coöperative bank, and the local banks, at the rate of interest which has been adopted, have brought about the following state of affairs: that a payment of a dollar a month results in a return of $200 in 12 years. Consequently at the end of 12 years he has, without making any direct payment to us, saved a sum sufficient to pay off the time note, and that sum, with the initial payment, brings him to a point where he may then look to a bank in the city and have a first-class bank mortgage and own his house under the same conditions that prevail among those in more fortunate circumstances. In many instances the owners of these houses are occupying them and virtually securing the ownership thereof at monthly payments which do not exceed the amount which they were previously paying as rent for tenements in which they never had any lasting interest.

We built first in 1915 twenty-seven of these houses and thirty more in 1916. The prices in 1915 ranged from $2850 to $4000; in 1916, from $3600 to $5200.

The cost of these houses was 16 cents per cu. ft. in 1915, and 19 cents in 1916. Mr. Atterbury informs us, however, that the same house we have been constructing was constructed in 1916 in Tennessee for 10 cents per cu. ft.

It is too soon for us to tell what we find registered in increased loyalty and increased work in the factory due to this one project alone. We feel sure that the effect will be to attach the workmen to our company. On the other hand, we have been careful not to chain them to the soil. The possessor of an Indian Hill house may leave our employ and still retain his home. The purchasers of our houses are also free to sell, this provision only being made, that having a bona fide offer in writing from another they shall be prepared to offer the house to us at the same price, so that if we do not approve of the new village occupant we may take the house over and seek new residents for ourselves.

The increasing village life has been interesting. The owners of these houses have formed their own improvement society and have recently made appropriations for the beautification of their village. We feel sure that the work has been started successfully and we look forward to greater influence in the future.

EMPLOYMENT METHODS AS FOLLOWED BY THE NORTON COMPANIES

By E. H. FISH,[1] WORCESTER, MASS.

WITH the growth of any business there comes inevitably a time when the management feels its separation from the men who are actually engaged in production. Such a time is apt to come soon after the number employed pass the thousand mark; then it becomes necessary to find some organized means of keeping the management and the workmen in touch with each other and in harmonious relations.

It has been customary in the last few years to use the labor turnover as an index of the degree to which the management is successful in keeping in close touch with its employees. At present the labor turnover of manufacturing establishments throughout the country will average in the vicinity of 400 per cent. This, however, takes in all kinds of shops under all varieties of management. The shops which have made conscious efforts to establish better relations are able almost invariably to show a much lower rate of turnover. It has sometimes been said that the only thing our employees want is money. If this were so then the lowest rate of turnover would be in the shipyards and munition plants where the highest wages ever known are being paid. The contrary is true, however, as they are running up to or over the average rate for the country in almost all cases. No one factor can be depended on to diminish this percentage, but all of them working together will surely, as in our own case, cut the labor turnover in quarters if not even more.

One of our activities along this line comes under the head of Employment. This means not merely the selection of the best men from a rather discouraging supply, their physical examination, the placing of them in positions best suited for their physical and mental power, but following them up while they are with us and especially as to the reasons for which they leave us when they do go.

The study of the reasons why men leave is one which almost every concern will find very productive of results, as it often indicates that there is quite a variance between the reasons which are advanced by the foremen and those given by the workmen themselves. If there were only one thing which could be done to better relations between the management and its employees, probably this one of keeping track of the reasons why the men leave would be productive of greater results than anything else. Possibly one of the things which this study is most likely to show is that hours of labor have much less interest to workmen than is sometimes thought: for example, in spite of the fact that on one side of the street we have 200 machinists working on 8-hour shifts, there has been no evidence of a desire on the part of nearly a thousand men on the other side working 10 hours, to secure transfers. In fact the total number of men leaving the Norton Grinding Company to secure shorter hours in the past year is only two.

The second department dealing with employees is the Hospital, and we find it very important that the Employment Department and other employee relations shall keep in the very closest touch with it and its records and advice so that all of these departments practically become one in their purpose and results.

The third department, that of Safety Engineering, has followed out the usual custom of providing mechanical safeguards until now the plant is so well covered that accidents seldom occur which can be traced to lack of mechanical guards. The large problem before the Safety Engineering Department today is that of the education of men in safe practices, by means of bulletins, lectures, moving pictures and other educational means.

Another department quite essential to better relations is that of training. This will be discussed by another speaker so that I need only refer to the fact that we find the labor turnover among men who have been given intensive training much lower than among those who have been thrown into their jobs without preparation for them. No one type of training can be prescribed offhand for all shops and all conditions. In many instances, especially such processes as can be taught in a short time and where increased value comes from dexterity, it is probably better to do the training on the job through foremen especially fitted for that work but without special equipment or separation from the usual work of the shop. On the other hand, where work requires thought,

[1] Employment Manager, Norton Grinding Co.

care and skill as differentiated from dexterity, the vestibule school has been found most acceptable. For work which can be taught on the job but where there is a body of related knowledge which can best be given in the classroom, the continuation school so strongly advocated by the National Association of Coöperation Schools has its value. All of these activities are going on here in this Company and all doing good work.

Other problems which must be faced for the benefit of the employees as well as the profit of the company, include transportation, especially for shops situated as so many are at a distance from centers of population so that means have to be provided for the workmen to get back and forth at a time when the transportation companies are rushed and least desirous of adding to their burdens. This problem has met a partial solution here by the running of two workmen's trains from the center of the city into our yards and by means of a trolley terminal nearby.

The problem of feeding is always with us and is one of the most unsatisfactory of solution of all problems. The line of least resistance is to secure some outside contractor to whom a concession can be given allowing him to feed and profit from the feeding of our employees. Where only one meal per day is served it is difficult to find a contractor who will agree to give real food such as we would wish our employees to eat and expect to make a profit from its sale. We have found it desirable to maintain a lunch room for our office employees which serves a luncheon, and also to maintain various dining rooms for workmen where ordinarily soup, pie, coffee and in warm weather ice cream are sold to the men with which they can supplement the cold food which they bring from home.

In addition to this we have found a great demand for the sale of milk and ginger ale which we have met by the establishment of milk stations in some buildings and milk wagons in others. There is no doubt but that the milk has a greater nutritive value and is the best from the employer's point of view. On the other hand, there are many workmen, especially those working in hot and dusty places, who feel the need of something like ginger ale to clear their throats and send them back to work refreshed.

Wash rooms are another thing which appeal to the men very strongly, and we have accordingly installed an arrangement making it possible for every man to use running water which has not come into contact with any other person. Our lockers are all of full height, which allows a man to wear as good clothes as he chooses and hang them in a way that makes them look acceptable when he takes them out.

You will also be interested in our gardens which are not exclusively a war measure as they have been conducted for several years, always with an increasing number of farmers. These gardens are each about 50 ft. by 75 ft., and are rented at the nominal charge of $1.50 per year to partially cover the cost of plowing and harrowing. This has had a large effect on our labor turnover. Last year, for example, when we had 600 gardens only three gardeners left our employ between the time of planting and harvesting. Under ordinary conditions we have a labor turnover of about 80 per cent. and during practically six months' time it can be seen that out of any given number of men a great many more would normally have left than did actually leave.

All these factors, together with our athletic association, minstrel shows, etc., help to build up a social interest which has a large holding power but which is not the result of any one activity.

VESTIBULE SCHOOLS

J. C. SPENCE, WORCESTER, MASS.

The munition firms of the United States failed to deliver British, French and Russian contracts on time in 1915 and 1916 simply because there were not enough tool makers in this country to make the jigs and gages for the manufacture of rifles and munitions alone, to say nothing of the increased demand for every other product of our factories, such as machine tools, engines, automobiles, rolling mills and so on, almost without end.

One of the consequences of this sudden demand for men was a ruthless attempt on the part of most of the war-order plants to obtain tool makers and machinists at any cost, and regardless of which going industries were hurt.

The ensuing confusion was augmented by the fact that the American Federation of Labor seized upon this time to send its labor agitators broadcast, with the result that practically no manufacturing center of any consequence, on the eastern seaboard, at least, escaped having very bitter strikes.

The manufacturers of the country were almost wholly unprepared to handle the situation, in so far as shortage of skilled labor was concerned. They had never before been faced by exactly this same problem. They had had keen competition for help several years previous during the very rapid expansion of the automobile business, but nothing that approached this new state of affairs.

Practically the only remedy used by the majority of the struck plants, or plants whose help had left for the "Promised Land" of Bridgeport and New Jersey, was to send out representatives to steal skilled help from towns not yet affected by the fever. All, without exception, followed this practice. The manager who says he did not either failed or else he was not aware of the proselyting carried on by his organization.

The Norton Grinding Company realized in 1915 the uselessness of attempting to hire skilled men in a community crowded with business, and started a Training Department. We have not a true Vestibule School, as such a school is an adjunct of the Employment Department, and is used principally as an examination room for applicants. What we have done is very simple and can be duplicated by any factory practically without cost.

To start a Training Department only two things are necessary:

1 A manager who really wants to help the United States to win this war to the extent that he will do his share of the breaking in of the "rookies" of industry.

2 A workman or foreman who has the knowledge, and especially the patience, to keep everlastingly teaching green help.

The first objection raised by most managers is that they have neither the necessary equipment nor the floor space. This is a natural first thought, but is wrong for this reason: In every department, say, in a machine-tool shop there is a certain amount of simple work to be done. This applies even to the tool room. It is the custom to give this simple work to the less skilled men, and to use the older machine tools, thus allowing the more valuable men to do the better work.

This being so, then why not simply take a lot of these machines, some of every variety, and concentrate them in one department? Some rearrangement of the shop may be necessary, but, on the other hand, this is usually a blessing, as most shops profit by frequent well-studied movings.

Start in a small way, and enlarge as you get experience.

[1] Superintendent, Norton Grinding Co.

Sometimes you will find that you have to overcome a deep-rooted resentment on the part of those foremen and workmen who served a long-term apprenticeship against any "presto, change!" method of producing help. Avoid this by starting small and letting it be thoroughly understood that the school is not intended to produce real machinists, but simply to take from the shoulders of the foreman the hard preliminary work of breaking in inexperienced help.

We do not attempt to make specialists in our Training Department. The student is taught a little of all of the common machine-shop operations, for we do not know in which department he will probably work. We simply wait for the opening to occur, and then the head instructor furnishes the student whom he thinks is best fitted for the job, regardless of the length of time served in the Training Department.

The Training Department runs along as a department of the shop, having its own schedule to meet in the production of simple parts and assembled mechanisms. This schedule calls for about one-half of the available labor of the department, the remainder being picked up throughout the plant in the form of odd jobs. It is really surprising, in times like these, how the foremen of a plant welcome an odd-job department. Here they get rid of all of the one-piece bothersome things that make fine jobs for the beginners, as this kind of work usually calls for the use of several different kinds of machines.

The toolroom also turns over much of its roughing work, as, for instance, the making of milling cutters, taps, reamers, arbors, etc., up to the very final operations that require experienced men.

If, by chance, the Training Department runs low in the right kind of work, that is, work that gives training in many branches of the trade, the head instructor has the right to commandeer any job in the main shop, no matter whether or not his department is equipped to do that job in an economical manner. For instance, if it becomes necessary to get some work to train men in the cutting of threads in an engine lathe, we go so far as to take work away from a turret lathe, even though the resulting threads show on our cost sheets to have cost us ten times what they ought to.

We pay an adult who has had previous experience at some kind of work the prevailing wage for common labor. Just now, in this section, this is 35 cents per hour. With our 55-hour week this amounts to $19.25, which is an inducement for many men, especially as there is the additional advantage of being able to make a good start toward learning the machinist's trade.

About a year ago France made it a law that each factory employing 300 people or more should maintain a separate Training Department.

Great Britain at the outbreak of the war tried to supply help through putting new workers on the machines, as we have always been accustomed to do, but soon found that the great numbers of newcomers swamped the old. The technical schools were resorted to, but they were abstract, academic and unacquainted with production requirements. Then school directors were replaced by factory managers, with foremen in charge of departments under these directors.

Finally British and French manufacturers came to see, as we must now see, that the obligation to produce war products in quantities implies another and equal obligation, i. e., the production by systematic training of mechanics who will produce the war requirements.

The manufacturer who would produce war materials must produce the machinists who will operate his plant. We must prepare to give up thousands of skilled men and make the semi-skilled and the inexperienced replace those we lose. There are not enough skilled workers in the country today to produce anywhere near the war products that we will need.

It is the immediate duty of every essential industry to take hold of the problem of remedying this condition. For the sake of helping our Government, we should have the foresight to do voluntarily what we will probably be finally forced to do by law or necessity. This war is going to last plenty long enough for every essential industry to get back a hundredfold any investment made in such an enterprise.

CORRESPONDENCE

Contributions to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

More Research Papers Desirable for A.S.M.E. Transactions

To the Editor:

The writer heartily concurs in the plea of Mr. Sanford A. Moss for more "high-brow" papers for record in our Transactions.

Although a decided improvement in the character of American research papers is noticeable of late years, apparently but few of our engineering publications care to consider papers treating technical problems on a mathematical basis.

In Europe the more important research papers attract considerable attention on part of the engineering profession, and the discussions which accompany them are not only of benefit to the author but also serve ultimately to establish a school of engineers highly proficient in some particular field of endeavor. A similar atmosphere in this country would no doubt lead to greater technical interest on the part of our engineers, and at the same time be decidedly helpful in advancing our research technique and bringing it fully abreast of the standard prevailing in Europe.

Meritorious research papers often represent the results of years of investigation and contain an abundance of interesting material that is invaluable to the engineering specialist. Such papers are well worth careful study, as they form a storehouse of original information to which recourse may be had repeatedly as various practical engineering problems present themselves for solution.

The lack of more intense interest in research papers appears to be due to the apprehension with which many of our engineers approach the more intricate mathematical papers, in which concentrated quantitative form one paragraph will often

require page upon page of descriptive matter to be as explicit.

While a few of our larger commercial establishments have fostered research work for their own benefit, the resulting material is generally not accessible to the public. Our public institutions, both state and national, have also made substantial contributions to engineering research work, but these efforts in themselves are hardly numerous enough to effect the rapid advance in scientific progress desired.

It is therefore up to the profession generally to offer greater encouragement to the trained individual investigator who from sheer love of science is ready to devote himself painstakingly to advance the particular phase of research work in which he is especially proficient. The integration of effort on the part of many such workers will surely lead to a far more rapid advancement in the art of scientific research. To bring this work fully abreast of the times, by all means foster the congenial atmosphere that is conducive to the further development of the research abilities of those so inclined.

Louis Illmer.

Boston, Mass.

Conservation of Coal

To the Editor:

More knowledge regarding the perfect combustion of coal should be acquired by all those who have to shovel it into the mouths of power or heating boilers or furnaces in large institutions and blocks of buildings using many tons each day.

Evening classes should accordingly be maintained by city councils in the schoolhouses, with expert instructors to lecture and demonstrate regarding proper methods of firing to get the best results out of the fuel and produce perfect combustion. Students at such classes should be shown samples of the various grades of coal, the heat value of each being explained, as well as the quantity of air it requires for perfect combustion, etc.

We require men to have an engineer's certificate before we allow them to take charge of a steam boiler, but I have yet to learn that an examination for such embraces the principles of obtaining the best results out of the coal burned to generate the steam. Often men are seen laying a heavy charge of fuel on a bed of incandescent coal too thick to allow the gases from such to be thoroughly mixed with the amount of oxygen supplied. A surplus of air is also frequently noticed with some firemen, who leave the feed doors open longer than they should. It is obvious that this air passing over new fuel is cold and cannot be mixed with the combustible gases; consequently the volatile portions of the hydrocarbons do no useful work. This lowering of the temperature of gases in the combustion chamber and flues is bad enough from the smoke-nuisance and coal-saving point of view, but to my mind a greater evil exists, and that is the unequal expansion and contraction of the boiler shell by such sudden changes of temperature. For a fireman who carries a thicker fire than necessary and then keeps his feed door open to reduce steam pressure is shortening the life of his boiler. A further waste of coal results when the boilers and steam-pipe surfaces are not insulated with asbestos.

If evening classes were established, the men should be informed of the percentage of waste of coal caused through various thicknesses of boiler scale and of flue scale, and, in fact, of all matters relating to getting the best results out of the coal.

The idea prevails that so long as a man is strong and can handle a shovel or firing tools, further knowledge is not required. If an applicant can show that he has fired a steam boiler before, it is taken for granted that he knows his business, regardless of the fact that he may not be acquainted with the rudimentary principles of combustion. If after attending the classes spoken of these men could answer the necessary questions they should be given a fireman's certificate, and as an inducement for them to practise what has been explained to them, they should receive a bonus or percentage on the amount of coal saved. Indeed, I would go further and suggest that all such men should be licensed by the Boards of Trade or similar responsible bodies of our cities if coal is to be conserved in the interests of ourselves and those who come after us.

James S. Kingston.[1]

Ottawa, Ont.

[1] Heating and Ventilating Engineer, Chief Architect's Branch, Public Works Department.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 190-193, inclusive, as formulated at the meeting of May 16, and approved by the Council on June 4, 1918. In this report, as previously, the names of inquirers have been omitted.

Case No. 190

Inquiry: Can the vertical joint of the inside furnace plate of a Manning boiler be welded by the autogenous process, under the proposed revision of Par. 186 of the Boiler Code as published in the March issue of The Journal? In the Manning boiler the collapsing pressure on the inside furnace sheet is fully supported by staybolts and this joint is under compression instead of tension.

Reply: It is the opinion of the Committee that if the vertical joint of an internal furnace which is fully supported by staybolts is welded by the autogenous process, it will meet the requirements of the proposed revision of Par. 186.

Case No. 191

Inquiry: Does or does not Par. 190 of the Boiler Code indirectly indicate that, unless definitely specified, and the specification distinctly stating, tension test sample shall be taken from the plate transverse to the direction of rolling, butt straps shall be cut so that their shorter or transverse dimension shall represent the longitudinal direction of the plate as rolled, in order that the greatest tension stress, the circumferential stress, sustained by the metal, shall be in the direction of the fiber produced by rolling?

Reply: It is the opinion of the Committee that the word "plates" in the fourth line of Par. 190 of the Edition of 1914 with Index refers to shell plates only and not to butt straps. It is proposed to insert the word "shell" before "plates" in the revision of Par. 190 in order to clearly indicate the intent of this rule.

Case No. 192

Inquiry: Is it the intention of the Boiler Code Committee to remove the limitation on the length of headers which may be made of malleable iron for use in connection with boilers under Par. 245? The present edition of the Code appears to limit the length of the header, whereas the proposed revision as published in the March issue of The Journal would remove this limit.

Reply: It is the opinion of the Boiler Code Committee that Par. 245 of the present edition of the Boiler Code does not restrict the length of cast iron or malleable iron headers, but that the limitation as to cross sections applies only to the form and size of the internal cross section, perpendicular to the longer axis of the header.

Case No. 193

Inquiry: Does the word "riveted" which is used in the proposed revision to Par. 273 of the Boiler Code to indicate a method of attachment of a "plate or plates" to the body of a safety valve as an alternate to stamping or casting the markings on the body, prevent the use of screws for the attachment of such plates?

Reply: It is the opinion of the Committee that the requirement for riveting is covered provided the plate is attached to the safety valve by screws with the outer ends riveted over so that the plate cannot be removed.

REVISION OF THE BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code, and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in The Journal with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes befo e the Rules are brought to the final form and presented to the Council for approval. This has been done, and the revisions were presented in the March issue of The Journal, pp. 234-247, in the April issue, p. 316, in the May issue, pp. 398-400, and in the June issue, pp. 468-470, in the form proposed for submission to the Council, except as they may be modified by editing without change of sense.

The revisions finally agreed on are those that have been published in the March, April, May and June issues of The Journal, with the modifications which follow. Although these modifications are in a sense final, the Committee would like any one who has an important criticism or suggestion to offer to submit the same immediately to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y.

May Journal, p. 398

Letter to the Council:

Add the following to the third paragraph relative to the Conference Committee:

The members of the Conference Committee are notified of and invited to attend all meetings of the Boiler Code Committee, and have rendered most useful assistance in preparing the interpretations as well as in coöperating with the Boiler Code Committee in revising the Code.

March Journal, p. 234

Letter to the Council:

Add to the list of names of those constituting the Boiler Code Committee, which follows the letter to the Council, the following:

Conference Committee

(Names to be inserted here)

March Journal, p. 241
and
June Journal, p. 470

Par. 292:

Cancel the entire revision proposed for Par. 292 and replace by the following:

292 No form of device shall be used for controlling the water supply, or the indications of the height of water in a steam boiler, unless it is approved by the state or municipal authorities enforcing these rules.

March Journal, p. 243
May Journal, p. 400
and
June Journal, p. 470

Par. 354:

Cancel revision proposed for Par. 354 in the March and June Journals, so that this paragraph will read as it originally appeared in the Boiler Code.

March Journal, p. 243

Par. 359:

Modify proposed revision of Par. 359 to read as follows:

359 *Double Grate Down Draft Boilers:* In boilers of this type the grate area shall be taken as the area of the lower grate plus one-quarter of the area of the upper grate.

March Journal, p. 243

Par. 363:

Modify the proposed addition to Par. 363 so that it reads as follows:

Temperature Regulator. A temperature regulator which will prevent the water from rising above 210 deg. fahr., shall be applied to all hot water supply boilers irrespective of the working pressure, and to hot water heating boilers in which the working pressure exceeds 30 lb. per sq. in.

March Journal, p. 244
and
June Journal, p. 470

Par. 374:

Cancel revision proposed for Par. 374 in the March Journal and revise it from the form in which it appears in the present edition of the Code by inserting the following after "in." in second line:

"but not to exceed 160 lb. per sq. in."

Add at the end of Par. 374 the following:

The separate sections when tested to destruction shall withstand a hydrostatic pressure of at least 1200 lb. per sq. in.

PAGE 109—APPENDIX

Insert in the Appendix the following:

Where state or municipal authorities allow the use of automatic water gages, they shall conform to the following requirements:

(Insert here rules 1 to 7 as proposed for Par. 292 on page 241 of the March Journal, and revised on p. 470 of the June Journal.)

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

PREPARE to Win! was the essential note struck at the Spring Meeting. No longer is it satisfactory to prepare for war—we must prepare to win.

Among the most helpful sessions to the undertaking of the United States in the present war was that on the Conservation of Fuel, under the auspices of the Committee of the Society of which Prof. L. P. Breckenridge is chairman, and attended by the representative men of the nation.

Another feature essential to winning the war is Emergency Technical War Training. The session on this subject was opened by an address by Prof. Arthur L. Williston, chairman of the Society's committee for this important activity. Others who addressed the meeting were Lieutenant André Morize, of the French Military Commission, and Major James E. Cassidy, of the 301st Engineers, an official observer at the front in 1916.

Notwithstanding the intensive war period and the fact that a year ago our Society met in Cincinnati, a central city, and jointly with another large organization, the Machine Tool Builders' Association, the attendance at the Worcester convention was larger than at any previous Spring Meeting, namely 986, of which 472 were members and 514 guests. Whereas the effort was concentrated on Win the War activities, and nothing was allowed to distract our main attention from these features, nevertheless the moments of relaxation were occupied by the wonderful program arranged by the Worcester Convention, permitting the members of the Society to enjoy the delightful friendships they have with our members and friends in Worcester, and to develop new acquaintanceships.

The beautiful scenery in and around Worcester, and the automobile ride to Concord, Lexington and the Wayside Inn, further added to the pleasures of the Spring Meeting.

In the general meeting before the whole Society Mr. Warner and Prof. Kent gave eloquent tributes to Prof. F. R. Hutton, who passed away just previous to the meeting. Prof. Hutton as Secretary for nearly a quarter of a century through its formative period had developed the personal as well as the professional side of the Society's work. In regarding, therefore, the splendid arrangements provided by the Worcester Committee, the ideal as expressed by Prof. Hutton in his Presidential Address for a convention of the Society was fully attained.

The spirit of rendering service which is now uppermost in the minds of all the people had birth quite as early in the engineering societies as in any other group of America's citizens. This is evidenced by the words used last February in the dedication of the new Engineers' Club in Dayton, Ohio, to the "dissemination of truth and the creation of civic righteousness."

One of the secrets of the complete success of the Worcester convention was the fact that it was our members who in their capacity as most active citizens in the drives of the Red Cross, Liberty Loan and Y. M. C. A. in Worcester, were naturally those that were grouped together on the Local Committee for our Spring Meeting, and, having worked out all the activities of these campaigns to a wonderful degree of success, it was to be expected that our convention should attain the same standard.

At the Council Meeting the report of the Special Committee on Readjustment of the Industries for War Work was approved, and a committee authorized to be appointed by the President. It is expected shortly that not only will there be a committee but that there will be regional representatives coöperating with the other instrumentalities of the nation. Dr. Hollis has with especial happiness expressed the idea that this is not an engineers' war any more than it is a financial war; but it is a war in which engineering is greatly employed, and the opportunity for service by our profession and the Society as an instrument of the profession could not be greater.

General March in his remarks to the graduating class at West Point this month stated:

"You are face to face with the most glorious adventure in the history of the world—a modern crusade, where an entire nation, without thought of territorial aggrandizement or of material gain, has planted its standard upon the soil of France in order that freedom shall be guaranteed to posterity. Go in and win!"

CALVIN W. RICE,
Secretary.

Council Notes

A WELL-ATTENDED meeting of the Council was held in the Hotel Bancroft, Worcester Mass., on June 4, 1918, in connection with the Spring Meeting of the Society. There were present:

Charles T. Main, *President;* Charles H. Benjamin, Arthur M. Greene, Jr., James A. Hartness, Ira N. Hollis, D. S. Jacobus, George A. Orrok, Charles T. Plunkett, W. R. Warner, W. H. Wiley, *Treasurer;* D. R. Yarnall L. P. Alford, *Chairman of Meetings Committee;* Jesse M. Smith, *Chairman of the Committee on Constitution and By-Laws;* Calvin W. Rice, *Secretary*, and W. E. Bullock, *Assistant Secretary.*

National Research Council. The President announced that in response to the invitation of the Engineering Committee of the National Research Council he had appointed Past-President John R. Freeman to sit with them in the discussion of their mechanical engineering problems.

Spring Meeting, 1919. It was voted to hold the next Spring Meeting in Detroit, Michigan, on a date to be mutually arranged by the Committee on Meetings and the Detroit Local Committee.

Committee on Readjustment of Industries for War Work. The report of this Committee suggesting ways in which the Society might serve the country in the matter of readjusting industries for war work was accepted, and the President was authorized in his discretion to appoint a committee to carry out the recommendations.

Boiler Code Committee. Interpretations of the Committee in cases 190 to 193 inclusive were approved with slight changes and ordered printed in THE JOURNAL. *Replies of the Committee* to communications from Mr. J. A. Hance and from the State Industrial Commission were approved.

Enemy Alien Members. A recommendation to drop from the membership all those who do not comply with the "Trad-

ing with the Enemy" Act, and all alien enemies was referred to the Engineering Council for advice as to what action this Society should take to be in accord with the other Founder Societies.

Communications. The Secretary read a letter from the family of Prof. F. R. Hutton, acknowledging the wreath of the Society and the sentiments it conveyed.

A communication from Sir John A. F. Aspinall expressed his thanks to the Council for its congratulations upon his election to the presidency of the Institution of Civil Engineers.

Quorum of the Council. The following By-Law was approved to take effect immediately after the constitutional amendments to be voted on at the Business Meeting the following day were made: "The number of persons constituting a quorum of the Council shall be one-third the number of members of the Council then in office."

Adjournment was taken to reconvene September 20, or at the call of the chair.

CALVIN W. RICE,
Secretary.

Readjustment of Industries for War Work

PRESIDENT MAIN TAKES IMPORTANT STEP SECURING COÖPERATION OF OUR SOCIETY WITH WAR INDUSTRIES BOARD

FOR the purpose of developing new industrial resources to meet the war demands of the Government, and quickly to disclose additional means of increasing production, the War Industries Board has just established a Resources and Conversion Section. Mr. Charles A. Otis, of Cleveland, former president of the Cleveland Chamber of Commerce and a member of the Board of Directors of the Chamber of Commerce of the United States, has been appointed Chief of this Section.

To carry out the plans of the War Industries Board, it has been decided to divide the country into twenty regional groups and to organize each region through the commercial organizations within the region.

In each of these regions all types of industry represented in the membership of the business organizations and in addition all industries which may not be a part of such membership will be invited to coöperate.

The purpose of this regional system is immediately to make a careful survey of every section of the country to determine what industries not now doing war work may be utilized for such work, and also to ascertain what industries already engaged on work for the Government are able to take on additional contracts or increase their production of munitions and war supplies.

Utilizing our Local Sections organization, President Main has appointed the following members of the Society to act as its representatives on each of the Regional Committees of the Resources and Conversion Section of the War Industries Board:

Bridgeport, Conn.	Harry E. Harris
New York City	G. K. Parsons

The President has also created a national committee of our Society on Readjustment of Industries for War Work. Mr. George K. Parsons, the chairman of our committee on this same subject, who was appointed as the outcome of the recent successful meeting of the New York Section on Non-Essential Industries, is chairman of the main committee. The other members of the national committee are F. A. Scheffler and Erik V. Oberg.

The action of President Main is in accordance with the action by the Council at its meeting in Worcester, of carrying out the recommendations of the Committee on Readjustment of Industries for War Work, and the President chooses the above method as the best means of rendering effective service by offering our organization to an agency already established for carrying on the work.

Desirable Constitutional Changes

It has been said that an ideal constitution of a society should "embody organization structural principles only and provide for nothing except members, officers and money." Details should be "left to by-laws." These statements are sound; a society that is not moribund is an elastic thing, and its development should not be hampered by the constitution curtailing future desirable activities.

On the other hand, the interests of a society are the interests of its members and should at all times be conserved and safeguarded by a constitution which limits things which should be limited.

The amendments to our Constitution adopted at the Spring Meeting at Worcester adhere to the principle that a simple constitution is best by reducing the number of constitutional standing committees, or Standing Committees of Administration, from ten to six.

The Standing Committees of Administration are now Membership, Finance, Meetings and Program, Publications and Papers, Local Sections, and Constitution and By-Laws. The former standing committees on House, Library, Research, Public Relations, and Standardization are now transferred to the By-Laws, and more may be added to their number at the discretion of the Council.

Analyzing the effect of these changes on the development of the Society, the six committees in charge of the six major activities now have a representative at all Council meetings to take part in all deliberations. Coördination of these six activities is secured through the contact of these representatives, which occurs under the most advantageous circumstances, simultaneously with the meeting of the governing body of the Society. The new arrangement therefore presents attractive possibilities.

That the members desired the Sections Committee included in the new standing committees of administration is a recognition of the potency of this activity. The Local Sections movement presents practically unlimited possibilities, and every step necessary should be taken which tends toward its full

realization. The Sections Committee has recently taken great strides forward; it has recommended autonomy to the Local Sections, and the autonomy has been approved in principle by the Council and new amendments proposed to the Council.

The changing of the names of the Meetings and Publication Committees to Meetings and Program, and Publication and Papers, is the idea, long since conceived, of the late Professor Hutton, who was a student of the Society's policies and the constitutional provision for them. The new names indicate more clearly the functions of these committees, as they have been in force for some time.

The changes in the methods of the Society's organization are but indications of a desire to harmonize the principles of government and to recognize the will of the membership. They are not even new indications, because ever since the Society was formed, and throughout all its successful development, the interest of the members in these things has been as keen as now. The point is that until recently there has been no opportunity for expression.

That this interest is an ever-present thing is illustrated by an example which it is proper to insert here. For some time past the President has been selecting the regular Nominating Committee for officers in consultation with members selected by groups of the Local Sections. By initiative of the Council itself, which recognized the advantages of the new method, a constitutional amendment was proposed at Worcester which takes this power of appointing the Nominating Committee entirely out of the hands of the President and places it, through the Sections, in the hands of the voting membership.

Report of the Nominating Committee

The following is the report of the Nominating Committee of the American Society of Mechanical Engineers:

The Committee held its first formal meeting at the Hotel Bancroft, Worcester, Massachusetts, on Wednesday, June 5, 1918. The meeting was called to order at 9:30 a. m., and adjourned at 1 p. m. Prof. L. P. Breckenridge was elected chairman.

The following members were present: L. P. Breckenridge, *Chairman*, New Haven, Conn.; Major Thomas E. Durban, Erie, Pa.; William P. Caine, Ensley, Ala.; George R. Wadleigh, St. Louis, Mo. Major C. F. Hirshfeld, Detroit, Mich., was absent but submitted a letter with his nominations.

After carefully considering the names submitted, the following nominations were unanimously approved:

For President:

DEAN MORTIMER E. COOLEY, Ann Arbor, Mich.

For Vice-Presidents:

F. R. LOW, New York City.
HENRY B. SARGENT, New Haven, Conn.
JOHN A. STEVENS, Lowell, Mass.

For Managers:

CHARLES L. NEWCOMB, Holyoke, Mass.
F. O. WELLS, Greenfield, Mass.
DEAN C. R. RICHARDS, Urbana, Ill.

For Treasurer:

WILLIAM H. WILEY, New York City.

As required by the By-Laws, we are submitting with this report the written consent of each nominee to serve if elected.

Respectfully submitted,
(Signed) L. P. BRECKENRIDGE,
Chairman of the Nominating Committee.

Society Service

Our Society is constantly supplying information to its members, as well as to other individuals or other organizations, on technical subjects, through the facilities of the Library and the acquaintance of the Secretary and office staff with the individual members and committees throughout the country. It is usually possible to refer such inquiries to specialists, who have always indicated their willingness to supply information to any reasonable extent; and often, indeed, our members put themselves to a great deal of trouble to help other members who may be in need of definite information which they are able to supply.

A case in point is an inquiry which came from India a few months ago with regard to the equipment of a mechanical-engineering laboratory. Through the courtesy of several professors of engineering who had recently equipped laboratories in this country and through helpful suggestions of various firms the desired information was supplied, as indicated in the accompanying letter:

TO THE EDITOR:

I thank you and the several firms and individual professors who at your instance have been kind enough to send me valuable information regarding the equipment of a suitable Mechanical Engineering Laboratory. I have thanked the several firms and professors separately.

I shall soon submit figures and specifications for the approval of the University. If the items be included in the next official budget, I shall be able to place orders with the firms or their agents, if any, in India.

Yours very truly,
(Signed) S. SETTI.

Malleswaram, Bangalore, India, March 11, 1918.

Dues of Members Being Remitted

Under a provision of By-Law, B 16, exempting from dues any member who has paid dues for 35 years, the following members have been granted such exemption:

Name	Date of Election	Name	Date of Election
Alden, Geo. I.	1880	Hunt, R. W.	1880
Allen, F. B.	1880	Kent, Wm.	1880
Baldwin, Wm. J.	1882	Lanza, Gaetano	1882
Bancroft, J. S.	1880	McEwan, J. H.	1882
Betts, A.	1881	Marx, Henry	1880
Bond, Geo. M.	1881	May, De Courcy	1881
Burdsall, E.	1880	Porter, H. F. J.	1880
Byllesby, H. M.	1882	Sellers, C., Jr.	1882
Clarke, Chas. L.	1882	Smith, A. W.	1880
Cloud, John W.	1880	Smith, G. H.	1881
Cogswell, Wm. B.	1880	Smith, Oberlin	1881
Coon, J. S.	1880	Tallman, F. G.	1881
Cox, J. D.	1881	Thomas, E. W.	1880
Emery, A. H.	1880	Townsend, David	1882
Forsyth, R.	1881	Trump, E. N.	1880
Halsey, F. A.	1882	Warner, W. R.	1880
Herrick, J. A.	1880	Weston, E.	1882
Hollerith, H.	1880	White, J. J.	1880
Howard, C. P.	1880	Wiley, W. H.	1880
Hugo, T. W.	1882	Wood, W.	1880
Worthington, C. C.	1882		

A list is now also being compiled of members who have reached the age of 70 years and have paid dues for 30 years. These are also entitled to the same exemption. This list will be published as soon as possible.

Steam Engineering Training School at Stevens Institute

The Navy Department has designated Stevens Institute of Technology, Hoboken, N. J., as headquarters for the new United States Steam Engineering School for the training of the engineering officers for the U. S. Naval Auxiliary Reserve.

This school is the only one devoted to training engineer officers for steam-engine service, and is a branch of the large training school now located at Pelham Bay Park, N. Y. It is contemplated to make a five-month course for the training of an officer; one month to be devoted to military and ship duties training at Pelham; one month at Stevens to receive the preliminary requirements and duties of an engineer; one month in inspection and repair duties at local shipyards, machine shops and boiler shops; one month at sea in the engine rooms of different types of boats; and one month subsequent training and examination at Stevens.

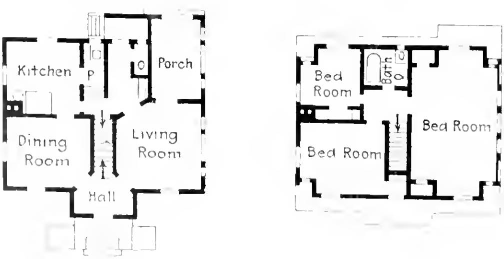
The instructors for the School with the exception of the Civilian Director will be regularly appointed commissioned officers of the United States Naval Auxiliary Reserve and will be selected primarily for their special work.

The school is open to men between twenty-one and thirty, who are physically qualified, of thorough ability and officer-like character, and who have completed the engineering course at any recognized technical school. Any men can enroll with the proper enrolling officer by securing from the draft board a letter of release which in all probability can be obtained for this purpose, provided the men are not included in the current draft quota. A graduate of the School will be commissioned an Ensign in the U. S. Naval Reserve Force.

For additional details application can be made to the Civilian Director, U. S. Navy Engineering School, Stevens Institute, Hoboken, N. J.

Workmen's Model Homes

Those who visited the Indian Hill Community of the Norton Company during the Worcester Meeting were favorably impressed by the architecture of the model houses, designed by Grosvenor Atterbury of New York. For economy of construc-



FIRST FLOOR SECOND FLOOR

Plan of Model Indian Hill House

tion and convenience of arrangement these houses could hardly be surpassed, and it will be of interest to Journal readers to see the floor plans of one of the designs, reproduced herewith.

At the convention of the N ional Association of Purchasing Agents on May 22, 1918, a resolution was passed advocating the standardizing of the 6 x 9 in. size as a primary standard for catalogs, and the $8\frac{1}{2} \times 11$ in. as a secondary standard.

Lessons From Our Medical Friends

In his presidential address before the American Medical Association, Dr. A. D. Bevan cited some striking facts about the Association, which is recognized as the leader in the organized medical profession of this country. Some of these lessons we might take to heart:

"It is now more important than ever that the admirable activities of the Association should be continued and amplified, and that steps should be taken to meet the new problems that will confront the Association after the war . . . But these things can and must wait on the one great problem that confronts us now, *the winning of the war.*"

"At the outbreak of the war, the American Medical Association offered to the United States government its entire organization and machinery to assist in the enormous expansion that became necessary. Through the officers of the county societies, the state societies, and particularly through the columns of The Journal, the needs of the government were placed before the organized profession of the country, and they responded splendidly to the call. So far 25,000 have gone into the Medical Departments of the Army and Navy. No other profession or calling has responded more promptly to the needs of the country than the medical profession. The great bulk of the medical men who have gone into government service were members of the American Medical Association."

"The demands made on the medical profession by the war are so great that it is evident that in order to secure the necessary number of medical men for the government, and at the same time prevent hardships in some communities and institutions, it is necessary to organize the entire profession of the country in a systematic way. It therefore became necessary for the American Medical Association, acting with the Surgeon-General's Office, to take a census of the available medical men in the United States in each state, in each country, in each medical school and in each hospital, and to attempt to secure from each one of these different units at least 20 per cent. of the medical men. This plan will enable the government to secure the necessary number of medical officers for an army of 5,000,000 men or more, and a navy of 1,000,000, without any great hardship to any community or to any institution."

"Profiting by the experience of the great nations that entered the war in 1914, the medical profession of the country, and the government, have very wisely taken steps to prevent the disruption of our medical schools, and I am glad to say that our national government adopted the suggestion made by the Surgeon-General to allow medical students to be commissioned in the enlisted Medical Reserve Corps and have them detailed to complete their medical education and to serve a year in a hospital as interns before they are called into active service."

"The United States is the only great reservoir of medical men in the world. The medical professions of Great Britain and France, of Italy and Belgium, and this is probably more true of enemy countries, have been well-nigh exhausted by this war. They delayed making plans for a continued supply, their medical schools became disrupted, and they are already suffering for medical men in their armies and in their civil life."

The Cincinnati Section Committee on Special Training Courses for Women, which consists of George Langen, J. B. Doan and R. T. Hazelton, has requested the Ohio Mechanics' Institute, Cincinnati, O., to give a course in intensive training in mechanical drawing for women. This course will begin on June 24, and it is entirely probable that other courses for women will follow.

AMONG THE LOCAL SECTIONS

THE Sections' Conference at the Worcester Meeting was attended by the following: D. Robert Yarnall, Alex. D. Bailey, Louis C. Marburg, A. L. Rice, W. Herman Greul, G. W. Galbraith, W. C. Brinton, R. Collamore, C. H. Bierbaum, W. W. Macon, G. K. Parsons, G. R. Woods, R. W. Adams, H. P. Fairfield, H. N. Dawes, J. C. Smallwood, A. C. Ashton, L. P. Breckenridge, J. C. Kingsbury, E. L. Fletcher, H. E. Harris, W. P. Caine, E. H. Lockwood, W. G. Starkweather, E. Smith, C. C. Cariss, E. L. Folsom, Calvin W. Rice and E. Hartford, representing in all thirteen Sections.

Mr. W. Herman Greul, Secretary of the New York Section, told in a very interesting manner of the way in which the meetings of the Section were being developed. Supplementing his statement Mr. W. C. Brinton showed a number of slides which gave graphical statistics as to the growth of the membership over a period of years; as to individual grades and total membership. Data was also given as to the attendance figures at the New York Section meetings, showing those attending according to their respective ages and also as to the period of time they had been members. These figures will be further developed and published in a later edition of The Journal. The activities of each of the Sections represented were described in turn by members of the Section in attendance and much of interest and value was developed.

Mr. D. Robert Yarnall, Chairman of the Committee on Sections, told of the recognition being accorded by the Council to the activities of the Sections, and emphasized the big step forward in making the Society truly democratic, through the presentation at the Business Session of an Amendment to the Constitution whereby the voting membership would elect the Nominating Committee, using the organization of the Sections to carry out the election.

The Secretary of the Society and also the Secretary of the Committee on Sections visited a number of the Sections during the month and reported a keen interest in the affairs of the Society in all sections of the country. The Committee on Sections will give considerable attention during the summer to planning for next year's activities and it will thereby be possible to get a flying start in the fall, with a series of meetings of considerable current interest. Likewise a number of new Sections are contemplated and the members in districts where Sections are not now organized are encouraged to develop interest in a Section in their respective localities. The Committee on Sections will be glad to contribute assistance.

Duluth Engineers at Get-Together Dinner

The engineers of Duluth, Minn., have taken the first steps to form a Duluth Engineers' Club by meeting at a get-together dinner on the evening of May 20th, at the Kitchi Gammi Club, Duluth.

At present Duluth has no club embracing all engineers. About thirty years ago a movement to organize was initiated but was not completed. The city has many other representative clubs and ranks high among other cities of the country for its activities and discussions of public questions. The environment is splendid for the growth of an engineers' organization. There are within reasonable distance of Duluth, over a hundred members of the four large national engineering societies, a number of members of the lesser engineering societies and many non-members. Until the successful formation of the Duluth Association of Civil Engineers about three years ago, these engineers had no common ground of meeting, no means to render their united thought effective on questions concerning the welfare of the profession or to promote the civic activities of their skill.

The Duluth Association of Civil Engineers, however, can and does represent only a small part of the whole body of trained technical men. Something bigger and broader is needed. With this view in the minds of the Civil Engineers, the Duluth Association in March, 1917, appointed a committee of Mr. W. H. Hoyt, Mr. W. B. Patton and Mr. W. H. Woodbury to develop a plan for a Duluth Engineers' Club. This committee has studied the situation carefully and is now ready to help in the development.

Its first important move was the call sent out for the above dinner to all members of the four main national engineering societies who lived within suitable distance of Duluth to attend and take part in the discussion. Some seventy engineers were present and took an active interest in the movement. Favorable responses were received from others who could not be present during the evening. The committee prepared an excellent program of talks and lantern slide pictures.

President F. E. House of the Duluth & Iron Range Railroad and retiring President of the Duluth Association of Members of the American Society of Civil Engineers, acted as toastmaster. In opening the program, he briefly outlined the objects of the meeting, and called on Mr. W. H. Woodbury to outline the plan of the formation of an engineering club. Three objects of the club were given by him; first, professional; second, social; third, civic. Four plans of membership have been considered: first, to have an organization for all professional engineers, junior engineers and associates, with different status for each; second, an organization made up of members of the four big national societies; third, an organization of members and a limited number of associates; and fourth, professional engineers only, all on an equal standing.

Mr. W. H. Hoyt reported preliminary suggestions for arranging a home for the club.

Acting on a resolution offered by Mr. T. W. Hugo, Emeritus Member of the American Society of Mechanical Engineers, that steps should be taken to form an engineers' club in Duluth and that a committee be appointed to develop the plan, Mr. House appointed a committee of eight representative engineers as follows:

American Institute of Electrical Engineers:
W. N. Ryerson, *Chairman*, Walter F. Schwedes.
American Institute of Mining Engineers:
Edwin J. Collins, Walter C. Swart.
The American Society of Mechanical Engineers:
Oscar B. Bjorge, W. H. Gallagher.
American Society of Civil Engineers:
W. H. Hoyt, W. H. Woodbury.

It is hoped that this committee will make such progress that another meeting can be called very shortly to put into effect their decisions.

While it is recognized that engineers are busy with war activities and responsibilities, it is felt that this is the time to unite the whole profession in one effective body promoting the interests and welfare of the profession and rendering service to the community. War has shown the great responsibility and opportunity of engineers to direct and do the work of the nation. The progress made by the national engineering societies in unifying their efforts toward securing the proper recognition and employment of their talents to the fullest degree has been reflected by many cities in the formation of strong, well-conceived engineers' clubs. Duluth has a large list of engineers of high standing as individuals and the leaders of the movement for a club are very optimistic of the strength and success possible.

The program of the night included addresses by men of nationwide reputation in the engineering field: Dean John Allen of the College of Engineering of the University of Minnesota spoke on the heavy call for engineers, the depletion of the numbers of students attending the universities and the thinning of the ranks of their instructors. He urged upon the engineers present, the necessity of encouraging young men to take up engineering studies in order that deficiencies in numbers of engineers may be prevented.

Mr. Calvin W. Rice, National Secretary of The American Society of Mechanical Engineers, brought greetings from his Society to the engineers of Duluth, and also read a telegram from the American Institute of Electrical Engineers expressing good will for the organization of a club and hoping their members would take an active part as well as form a local branch of the Institute. Mr. Rice's talk was full of eloquent appeal to the engineers to take up the work and place on its banner the idea of high service for the general welfare of the commonwealth and profession. He set forth that it is for the engineers of America to render the loftiest expression of its objects in the organizing of any technical society.

Mr. Kirk L. Strickland, erecting manager of the American Bridge Co., Chicago, gave a talk illustrated with lantern slides on the Union Pacific Railway Company's new bridge over the Missouri River at Omaha.

Mr. Richard Khuen, Jr., member of the Board of Direction of the American Society of Civil Engineers, and who had a hand in building the famous Hell Gate Bridge at New York, described the work and with lantern slides illustrated the construction in a very interesting manner. A moving-picture film was used to show further how the job was arranged.

Section Meetings

BALTIMORE

May 22. At the final meeting of the Section the following officers were elected: A. E. Walden, chairman; Wm. L. DeBaufre, vice-chairman and A. G. Christie, secretary-treasurer.

The address of the evening was delivered by W. H. Blood, Jr., of the American International Shipbuilding Corporation, on Hog Island, the greatest shipyard in the world.

The speaker called attention to conditions at the outbreak of the war and showed the steps that led up to the undertaking of the Hog Island enterprise. He explained in detail the relations of the Corporation and the Government and showed clearly that the undertaking had been grossly misrepresented in many statements appearing in print. He then discussed the difficulties in construction last winter and how in spite of all the yard was well ahead of schedule. The speaker next took up a discussion of many of the yard's details and impressed his hearers with the immensity of the undertaking.

The address was illustrated by lantern slides showing all stages of construction. These were very impressive.

Another paper by Charles R. Schmidt on The Coal Problem was handed to the Secretary. On account of the lateness of the hour, it was decided to read this by title only, to be taken up at a meeting next fall.

A. G. Christie,
Section Secretary.

BIRMINGHAM

May 16. The Atlanta Section were the guests at the Annual Meeting of the Birmingham Section. A very enjoyable and instructive inspection trip was made to some of the large plants in the district. Leaving the Tutwiler Hotel at nine o'clock the party proceeded to the plant of the Hardie-Tynes Manufacturing Co., manufacturers of marine engines and the party witnesed the manufacture of what is known as 1-lb. naval shells. A small section of the plant is devoted to the manufacture of these shells, where they turn them out at the rate of about 2,000 per week.

From the Hardie-Tynes Manufacturing Co., the party proceeded to the plant of the Birmingham Machine & Foundry Co., principally engaged at this time in the manufacture of 14-in. semi-steel naval practice shells and also large cotton compresses. Here was seen the largest boring mill in the Birmingham district; a mill of 16-ft.-diameter table, and at the time of inspection this boring mill was working on a large cotton compress platen weighing approximately 60,000 lb.

A trip was then made to the plant of Joubert & Goslin who make large castings for evaporators used in the sugar-refining industries.

After leaving Joubert & Goslin's the party arrived at the plant of the American Cast Iron Pipe Co. A trip through the company's industrial village for negroes known as West Acipco disclosed the fact that they are second to none in welfare work. This village has paved streets, stone and sanitary sewerage and numerous houses with large garden lots for their negro employees. All the houses are of different design, have plastered walls, are equipped with hot and cold water and, in fact, modern in every respect. A picture was taken of the group, numbering approximately 30, at the plant of the American Cast Iron Pipe Co. in front of their modern office building. The entire process of manufacturing pipe was noted at this plant and also the manufacture of large castings for the Air Nitrates Corporation at Sheffield and the experimental 8-in. semi-steel high-explosive shells. A dinner was then served at the Y. M. C. A., which is controlled and operated by the American Cast Iron Pipe Co.

Picture Taken of the Group at the American Cast Iron Pipe Company's Plant

In the afternoon the party proceeded to the Ensley Works of the Tennessee Coal, Iron & Railroad Company, where an inspection was made of the steel mill and furnaces.

At eight o'clock the party assembled at the Tutwiler Hotel for dinner and a business session. Mr. Klinck, Chairman of the Birmingham Section, after giving the Atlanta Section a hearty welcome, delivered a short talk on the achievements of the Section during the past year. Mr. Scott, Chairman of the Atlanta Section, in response, thanked the Section for the hospitalities extended and the very enjoyable inspection trip. He also extended an invitation to the Birmingham Section to visit Atlanta either this fall or next spring, and expressed the hope that the Baltimore, Birmingham, New Orleans and various other sections in close proximity could be induced to meet together in Atlanta at that time.

Vice-chairman W. F. Caine gave a short talk and pledged his best efforts in making the ensuing year count a great deal for the Section. Mr. Caine read a letter from the Detroit Engineering Society enclosing a copy of resolutions recently passed by that Society urging colleges and manufacturers to coöperate in the training of women to take the place of men in our industries. It was brought out in discussion that this was an excellent idea and that a great deal rested upon the patience of heads of departments in the manufacturing plants towards the successful training of women, and that whereas they would get their preliminary training in the college, their special training would naturally be obtained

after taking their place in the ranks of industry. It was voted that the resolutions submitted by the Detroit Engineering Society be adopted by the Birmingham Section and that publicity be given these resolutions and an effort made to bring about coöperation and the establishment of places of training for women.

Major F. H. Wagner, O. O. R. C., of the United States Army, who is engaged in work for the Air Nitrates Corporation, delivered a very interesting address on some of the problems that were being worked out in connection with the fixation of nitrogen. He brought out the fact that while detailed information could not be given at this time, when the war is over the engineers will be supplied with very interesting and helpful data on the various achievements that are now being made.

The Section was honored by having as a guest Secretary Calvin W. Rice, who made a most interesting and helpful address on various timely topics, as Unused Water Power, the Training of Women for Industrial Work, Liberty Motors, Gas Warfare, Coöperation in the Engineering Profession, the work of the Engineering Societies, the Dilution of Labor, etc. The main idea of his talk was to furnish food for thought and stimuate the Section in progressive lines and lofty ideals.

W. L. Roueche,
Section Secretary.

BOSTON

May 29. The Annual Meeting of the Boston Section was held at the Engineers' Club. After brief reports of the Executive Committee, the following were elected for the year 1918-1919 to serve on the Executive Committee: Geo. P. Aborn, Albert C. Ashton, Wm. W. Crosby, Edward M. Jennings, Elmer Smith and Wm. G. Starkweather.

President Charles T. Main and Past-president Ira N. Hollis were present and addressed the meeting, the latter giving some very interesting data on the fuel situation in Massachusetts. Mr. Ashton then told of the work accomplished by the Boston Section during the year, and the successful meetings which had resulted.

An eloquent and forceful address was delivered by Doctor Charles H. Eaton on America at the Gateway of Destiny. An enthusiastic audience of about one hundred persons listened to this address and later enjoyed light refreshments.

W. G. Starkweather,
Section Secretary.

CONNECTICUT SECTION

Meriden Branch

May 17. The annual meeting of the Meriden Branch of the Connecticut State Section was held at the Winthrop Hotel.

The entire list of officers were renominated by the special nominating committee, and were unanimously reëlected, as follows: C. K. Decherd, chairman; C. N. Flagg, secretary-treasurer; F. L. Rowntree, J. A. Hutchinson and Fred L. Wood.

Mr. R. W. Millard was the speaker of the evening and took for his subject "The Need of Systematic Training and Instruction of Workmen in the Factories." It was the sense of the meeting that a special committee should be appointed for this matter.

The experiences of the various members present, with Government work, was next discussed.

C. N. Flagg,
Branch Secretary.

ERIE

May 3. The following officers were elected for the year 1918-1919 on the Executive Committee of the Section: M. W. Sherwood, chairman; C. M. Spalding, vice-chairman; R. Conrader, treasurer and J. St. Lawrence, secretary. Following the business meeting Mr. James Burke, Mem.Am.Soc.M.E., gave an interesting talk on The Conservation of Material.

M. E. Smith,
Section Secretary.

MILWAUKEE

June 12. At a meeting of the Engineers' Society of Milwaukee, Mr. H. M. St. John of the Testing Laboratory of the Commonwealth Edison Co., delivered an illustrated lecture on Products of Electric Furnaces and the Cost of Their Production.

Fred H. Dorner,
Section Secretary.

NEW YORK

May 21. Under the chairmanship of George R. Woods, the subject of the meeting was a timely one on Labor Turnover, and was presented by speakers of prominence representing makers of ships, aeroplanes, ordnance and machine tools.

The first speaker, J. J. Pearson, outlined his work in the British Ministry of Munitions, and his labor-dilution service. Then Orrin W. Sanderson, Director of Labor of the B. F. Goodrich Co., outlined his work in that field, having to do with twenty thousand employees.

Mr. Dudley Kennedy, of the American International Shipbuilding Corporation, and who has charge of the shipbuilding plant at Hog Island, told of the methods employed in that work. Mr. H. F. J. Porter, consulting industrial engineer, outlined the broad principles of the work involved by the operations of the previous speakers. The specialized work that has been done to improve the labor problem was covered by the following speakers: John Calder, of the Aero Marine Plane & Motor Company, at Keyport, N. J., who spoke of the effect of the selective draft; Capt. Boyd Fisher, of the Ordnance Department, U.S.A., who told of the work carried on by the Government in the training of employment managers, and following him L. D. Burlingame, industrial superintendent of the Brown & Sharpe Manufacturing Company, outlined the work of his company in training women for employment. Mr. H. E. Miles, of the Council of National Defense, described the plans and accomplishments of the Council of National Defense to assist manufacturers to train women in their shops.

Major E. N. Sanctuary of the War Service Exchange of the Adjutant General's Office, and other representatives of the Government including the following joined in the discussion: Capt. J. J. Swan of the Committee on Classification of Personnel in the Army, and Mr. J. B. Densmore, Director of the U. S. Employment Service, for the Labor Department.

Mr. G. K. Parsons presented the following resolution which was adopted:

Resolved, That the Chair appoint a Committee to take immediate action to determine how the Society can render the greatest assistance in the solution of the problem of labor turnover.

W. H. Greul,
Section Secretary.

NEW ORLEANS

June 10. At the last meeting of the Louisiana Engineering Society Mr. Howard Egleston, Civil and Industrial Engineer of the New Orleans Association of Commerce, delivered a paper on The Present Situation as Relating to the Introduction and Use of Natural Gas in New Orleans. The speaker described briefly the natural-gas wells which have been successfully operated at Terrebonne Parish about forty miles from New Orleans. One of the wells is said to have the largest flow of any natural-gas well in the world. At present the chief obstacle of piping this gas to New Orleans is the difficulty of securing the steel for the pipe line, but mention was made of the possibility of using other material such as cast iron or reinforced concrete.

H. L. Hutson,
Section Chairman.

ONTARIO

May 27. At the Annual Meeting of the Ontario Section which was held at the Engineers' Club, Secretary Calvin W. Rice gave a very interesting talk on the activities of the Society.

Mr. J. H. Billings, Assoc.-Mem.Am.Soc.M.E., delivered a paper on Strength of Cast Iron in Bending as Affected by Variations in Cross Sections.

The results of the election of new members for the Ontario Section were announced as follows: R. W. Angus, chairman; C. B. Hamilton, secretary; James Milne; J. H. Billings and H. B. Ahara.

Chester B. Hamilton, Jr.,
Section Secretary.

Student Branch Meetings

Members of Student Branches are requested to notify the Secretary of any change in address as promptly as possible, in order to facilitate delivery of The Journal.

BUCKNELL UNIVERSITY

May 8. The following officers were elected for the ensuing year: G. F. Jammer, chairman; H. R. Pars, vice-chairman; H. J. Hann, secretary and B. J. Wilson, treasurer.

Professor Burpee delivered an interesting address on What Is Expected of the Engineering Student at Present.

H. J. HANN,
Branch Secretary.

UNIVERSITY OF CALIFORNIA

April 24. The election of officers for the ensuing year was as follows: J. Mora Moss, Jr., chairman; E. S. Smith, Jr., vice-chairman; G. C. Goldwaithe, secretary, and A. O. Montijo, treasurer.

A paper was presented by Llewellyn Boelter on The Tungar Rectifier.

LLEWELLYN BOELTER,
Branch Secretary.

CARNEGIE INSTITUTE OF TECHNOLOGY

May 4. The annual banquet of the Branch was held in connection with the last meeting of the year. The following officers were elected for the ensuing year: H. D. Krummell, chairman; W. J. Blenko, vice-chairman; D. C. Saylor, secretary and P. D. Wersant, Jr., treasurer.

Mr W. C. Bates, of the Fawcus Machine Co., gave an interesting talk on the automatic control of the torpedo, and showed how the Allies and Germany are striving for superiority, each enjoying brief periods of supremacy, which are soon annulled by a new invention which counteracts this temporary advantage.

Professor Trinks gave a short talk on the early days of the Institute, and several of the alumni present also spoke briefly about their experiences since graduation.

H. D. KRUMMELL,
Branch Secretary.

UNIVERSITY OF CINCINNATI

May 23. The following officers were elected for the ensuing year: L. C. Smith, chairman; H. Dangel, vice-chairman and G. H. Eilers, secretary-treasurer.

Mr. J. F. Pflum of the Heald Grinding Co., delivered an interesting paper on Time Allowances for Internal Grinding. Many samples of work were shown and time studies taken were discussed.

Professors Jenkins, Joerger and Shine briefly discussed accurate working limits.

C. L. KOLHIER,
Branch Secretary.

UNIVERSITY OF COLORADO

May 2. The following officers were elected for the ensuing year: R. F. Hamilton, chairman; W. K. Gray, vice-chairman and H. H. Herman, secretary-treasurer.

HARRY H. HERMAN
Branch Secretary.

UNIVERSITY OF ILLINOIS

During the last semester one meeting each month has been given up to the University War lectures for the College of Engineering. These lectures are intended primarily for engineers, and all of the engineering societies are devoting one meeting a month to the lectures. Subjects of national interest at this time are presented by men well qualified to speak upon the various subjects discussed. The members of the Student Branch feel that it is well worth while to forego one meeting of the Branch by itself in order to hear these lectures.

In addition to talks and lectures by faculty men, and other professional men, the Branch is at this time having a series of talks by student members. Pi Tau Sigma, a professional mechanical engineering fraternity at the University, offers each year a prize to the student member of the Branch giving the best talk on some technical or semi-technical subject before the Branch. A great deal of interest is shown in this contest, and some very good papers have been presented. A prize is offered to each of the four classes, in order to prevent unfair competition. The Branch has voted to send the best paper of the whole set to the parent Society to be entered in competition for the prize offered for the best student paper from all Student Branches.

C. Z. ROSECRANS,
Branch Secretary.

LOUISIANA STATE UNIVERSITY

May 7. A very interesting talk was delivered by Mr. Etheredge on the manufacture of sugar in Louisiana, in which he pointed out the difficulties to be overcome in using cane bagasse as fuel. Many lantern slides of the different kinds of machinery employed by the various refineries were shown.

May 29. The officers elected for the ensuing year are as follows: C. R. Strattman, chairman; C. R. Byrd, vice-chairman; C. Colomb, secretary and J. A. Scheuermann, treasurer.

A brief talk was given by Mr. Taddicken, of the Westinghouse Co., on the apprenticeship work in large shops.

C. R. STRATTMAN,
Branch Secretary.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

The annual election of officers resulted in the election of the following: Charles A. Chayne, chairman; Scott H. Wells, vice-chairman; Everett F. Doren, treasurer and Edward F. Pierce, Jr., secretary.

STUART H. CALDWELL,
Branch Secretary.

UNIVERSITY OF MICHIGAN

April 30. The following officers were elected: D. M. Ferris, chairman; S. T. Huette, vice-chairman; and A. D. Althouse, secretary-treasurer.

A. D. ALTHOUSE,
Branch Secretary.

MICHIGAN AGRICULTURAL COLLEGE

May 16. The following officers were elected for the ensuing year: A. E. Downer, chairman; E. Osborne, vice-chairman and E. C. Hoch, secretary-treasurer.

H. M. SASS,
Branch Secretary.

UNIVERSITY OF MINNESOTA

March 23. The following officers were elected for the ensuing year: G. H. Brennan, chairman; H. A. Abrahamson, vice-chairman; A. Baker, corresponding secretary; R. M. Foltz, recording secretary and M. S. Wunderlich, treasurer.

A very interesting talk was given by Prof. J. J. Flather, on Ancient Shipbuilding in which he discussed the most ancient forms of ships and the methods used in building them.

May 4. An open meeting was given at which Melvin Ovestrud, of the class '14 now in the employ of the Minneapolis Steel Machinery Co., gave an illustrated lecture on Shell Manufacturing.

A. BAKER,
Branch Secretary.

UNIVERSITY OF MISSOURI

April 25. A paper on The Poppet-Valve Engine was presented by R. T. Powers in which he pointed out the utility of the poppet valve in connection with high steam pressures and the application of this type of valve to the unaflow engine, the high pressures permitted and resulting high economies attained.

May 10. The following officers were elected for the ensuing year: Will Copher, chairman; K. K. King, corresponding secretary and Roy H. Jaeger, secretary-treasurer.

Mr. F. C. Hussey presented an interesting paper on The Manufacture of Dynamite in which the various operations of dynamite were fully explained.

J. W. BALDWIN,
Branch Secretary.

UNIVERSITY OF NEBRASKA

May 11. A business meeting was held which resulted in the election of the following officers for the ensuing year: V. E. Kauffman, chairman; W. L. Millar, secretary; Harvey Glebe, treasurer and L. F. Seaton, honorary chairman.

W. L. Millar,
Branch Secretary.

OHIO STATE UNIVERSITY

May 8. This meeting took the form of a banquet which was followed by the election of officers for the ensuing year. The following were elected: F. H. Cover, chairman; H. R. Ansel, secretary and V. Darnell, treasurer.

F. E. Smyser,
Branch Secretary.

UNIVERSITY OF OKLAHOMA

April 11. After a brief business meeting the following short talks were given: Advantages of High Pressure and Superheat by E. H. Reeves; Comparative Economy of Turbines and Engines by L. A. Humphries; Comparison of Different Means of Power Transmission by F. E. Waterfield; Oil versus Coal Under Boilers by R. V. Goodknight; Feedwater Heaters and Economizers by G. L. Barker; Injector, Rotating and Reciprocating Pumps for Boiler Feed by T. J. Bode; Types of Condensers and Their Economy by B. P. Stockwell and Boiler Explosions by C. D. Reasor.

May 7. The following officers were elected for the ensuing year: Geo. L. Barker, chairman; E. K. Warterfield, secretary and Theo. J. Bode, treasurer.

Talks were given on the following: Keokuk Power by B. P. Stockwell, Sioux and Fox Indians by Don Whistler and Emergency Motor-Truck Driving by E. H. Reeves.

B. P. Stockwell,
Branch Secretary.

UNIVERSITY OF PITTSBURGH

John F. Baker, the president for next year, delivered a brief talk on the aims of the Engineering Society for next year. An interesting address was then delivered by S. H. Orr on The Conditions Affecting the Coal Supply for Next Winter. Several valuable suggestions were made on the conservation of the fuel supply and the efficient operation of power stations. After discussion by the various members of the Branch the rest of the meeting took the form of a social.

John H. Allison,
Branch Secretary.

RENSSELAER POLYTECHNIC INSTITUTE

April 11. The following officers were chosen for next year: Robert I. Todd, chairman; James F. Dewey, vice-chairman; Chester G. Bragaw, secretary and Justin L. Smith, treasurer.

Professor Greene gave an illustrated talk on Mechanical Stokers showing the various types of stokers in general use.

Professor Daugherty then delivered a talk on Photography, explaining in detail the development of the camera from the pinhole type to its present form and by means of blackboard diagrams illustrated the different lenses and their defects.

Chester G. Bragaw,
Branch Secretary.

STEVENS INSTITUTE OF TECHNOLOGY

The following officers were elected for the ensuing year: G. H. Spencer, chairman; H. E. Beaven, vice-chairman and L. V. Aquadro, secretary-treasurer.

Lincoln V. Aquadro,
Branch Secretary.

UNIVERSITY OF WASHINGTON

May 14. The election of new officers was held with the following results: Fairman B. Lee, chairman; Corwin P. Rummel, vice-chairman; Ernest E. Bissett, secretary; Thomas R. Gunn, corresponding secretary and Lester R. McLeod, treasurer.

H. B. Sallee,
Branch Secretary.

ROLL OF HONOR

Angell, Harry J., Candidate, Engineer Reserve Officers' Training Camp, Camp Lee, Va.

Bernard, Harold E., Coast Artillery Corps, N. A.

Blake, A. D., Captain, Ordnance Officers' Reserve Corps, Engineering Bureau, Ordnance Dept., U. S. Army.

Boyer, George H., First Lieutenant, Ordnance Officers' Reserve Corps U. S. Army.

Blakeman, S. P., Private, 34th Squadron, 3d Prov. Regiment, Science and Research Division, Aviation Section of the Signal Corps, Waco, Tex.

Bosnian, Luther H., Sergeant, Ordnance Department, U. S. Army, Watervliet Arsenal, N. Y.

Brown, Claude C., Master Engineer, Senior Grade 434th Engineers, Camp Kearny, Cal.

Clarke, Leon L., Captain, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

Corey, Thomas H., Lieutenant, U. S. Naval Reserve Force.

Durban, Thomas E., Major, Ordnance Officers' Reserve Corps, Ordnance Department, U. S. Army.

Durley, Richard J., Captain, British Army, Imperial Ministry of Munitions, Ottawa, Canada.

Fellers, William M., Lieutenant (Junior Grade), U. S. Naval Reserve Force, Aeronautic Aide, Naval Air Station, Hampton Roads, Norfolk, Va.

Flewelling, Milton F., Candidate, Officers' Training School, Naval Auxiliary Reserve, Naval Training Station, Pelham Bay Park, N. Y.

Haines, Philip G., Co. E, 112th Regiment, U. S. Engineers, American Expeditionary Forces, France.

Hathaway, H. K., Lieutenant-Colonel, Ordnance Department, N. A.

Hayward, H. S., Lieutenant (Junior Grade), U. S. Naval Reserve Force.

Hill, Dudley M., Private, Co. 4, Coast Artillery Corps, Fort Howard, Md.

Hoffman, J. Roy, Aviation Section of the Navy, Massachusetts Institute of Technology, Boston.

Hoyt, Frank W., Lieutenant, Co. C, 6th U. S. Engineers, American Expeditionary Forces, France.

Jarrett, Hillard W., Chief Quartermaster, Naval Aviation, Inspection duty, U. S. Navy.

Kemble, Parker H., U. S. Marines.

Lance, C. C., Lieutenant, Engineer Officers' Reserve Corps, Co. 5A, Engineer Reserve Officers' Training Camp, Camp Lee, Va.

Le Valley, John R., Ensign, U. S. Naval Reserve Force, Annapolis, Md.

Malone, George B., Captain, Engineer Officers' Reserve Corps, 1st Regiment Replacement troops, Engineers School, Washington Barracks, Washington, D. C.

Magill, F. R., Sergeant, School of Motor Transportation, Camp Holabird, Baltimore, Md.

Matthew, Robert M., Private, Co. A, 30th Regiment Engineers, American Expeditionary Forces, France.

Moody, Frederick H., Captain, Infantry Depot, 116th Battalion, Canadian Infantry, England.

Morrison, Barrett W., Sergeant, Battery A, 1st Battalion, 1st Brigade, Field Artillery, Camp Jackson, S. C.

Newby, H. L., Private, Aviation Section of Signal Corps, Aviation Camp, Waco, Tex.

Nicoll, William L., First Lieutenant, Quartermaster Officers' Reserve Corps, office of Director of Storage and Traffic, Washington, D. C.

Penrod, E. B., Meteorological Section, Signal Corps, U. S. Army.

Pettis, John G., Chief Machinist's Mate, Aviation Section, U. S. Navy.

Poirier, Austin E., First-class Private, Meteorological Section of the Aviation Section of the Signal Corps, 3d Regiment, 33d Squadron, Waco, Tex.

Porter, Raymond E., Aviation Section of Signal Corps, U. S. Army, assigned to the Aviation Course, Massachusetts Institute of Technology.

Ritter, Ralph B., Second Lieutenant, Field Artillery, National Army, Camp Jackson, S. C.

Rowe, Harold E., Private, Troop B, 303d Cavalry, Camp Stanley, Tex.

Russell, Troy, Private, Co. C, 341st Machine Gun Battalion, 89th Division, American Expeditionary Forces, France.

Semans, F. Wendell, Second Lieutenant, Aviation Section, Signal Officers' Reserve Corps, Ellington Field, Houston, Tex.

Spencer, O. G., Captain, 9th Battalion, 20th Engineers, American Expeditionary Forces, France.

Spice, C. G., Captain, Ordnance Officers' Reserve Corps, Gun Division, Washington, D. C.

Viedt, H. B., Candidate, Officers' Training School for Steam Engineers, Naval Auxiliary Reserve, Naval Training Station, Pelham Bay Park, N. Y.

Voos, Fred W., Cadet, Officers' Artillery Training School, American Expeditionary Forces, France.

Wade, Alfred D., Headquarters Troop, 78th Division, Intelligence Section, American Expeditionary Forces, France.

Wainwright, A. V., Lieutenant, U. S. Naval Reserve Force, Bureau of Steam Engineering, Navy Department.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by July 15 in order to appear in the August issue.

CHANGES OF POSITION

Royce L. Beers has severed his connection with the U. S. Radiator Corporation, of Detroit, Mich., to enter the engineering department of the Bailey Meter Company.

George A. Armes, formerly engineer-in-chief, Union Iron Works Company, San Francisco, Cal., has become associated with the Moore Shipbuilding Company, Oakland, Cal.

Charles D. Cross has entered the employ of the Machinery Utilities Company, Inc., New York. He was until recently connected with the N. Y. C. R. R. Company, New York, in the capacity of assistant night foreman.

Burt C. Wear, formerly identified with the Tube Company, Lorain, Ohio, in the capacity of estimator, has become affiliated with the ordnance department of the U. S. S. Corporation, Ambridge, Pa.

George P. Sonn, until recently engineer with the Bridgeport Brass Company, Bridgeport, Conn., has accepted a similar position with the National Conduit and Cable Company, Hastings, N. Y.

L. K. Sillcox has assumed the position of master car builder of the Milwaukee Shops of the Chicago, Milwaukee and St. Paul Railway Company. He was formerly mechanical engineer with the Illinois Central Railroad, Chicago, Ill.

Norman G. Reinicker is no longer connected with the New York Edison Company, as assistant to chief engineer, having become associated with the power department of the Du Pont Engineering Company at Nashville, Tenn.

K. M. Irwin has resigned his position with the betterment division of the Stone and Webster Engineering Corporation, Boston, Mass., to take a position with Perry Barker, fuel engineer of the same city.

Harry V. Hunt, until recently general superintendent of the Consolidated Press Company, Hastings, Mich., has assumed the duties of general manager of the O'Neil Iron Works, Buffalo, N. Y.

Arthur S. Robinson has left the employ of the Hyatt Roller Bearing Company, Harrison, N. J., and has become affiliated with the Naval Aircraft Factory, League Island, Philadelphia, Pa., in the capacity of engineer.

Maurice F. Richardson, formerly plant manager of the Arlington Company, has assumed the position of manager of the Easton Car and Construction Company, Eason, Pa

Henry Cave has left the employ of the Davis Bournonville Company, Jersey City, N. J., where he held the position of director of technical research, and has become production manager of the S. K. F. Ball Bearing Company, of Hartford, Conn

William A. Drewell, superintendent of the M. T. Davidson Company, Brooklyn, N. Y., has assumed the duties of vice-president and general manager of the Providence Engineering Corporation, Providence, R. I.

Raymond A. Coll, formerly engineer with Robert T. Pollock Company, Boston, Mass., has entered the employ of the Colt's Patent Fire Arms Manufacturing Company, Hartford, Conn., in the capacity of engineer in the machine-gun department.

Sidney C. Singer, formerly superintendent of distribution, Syracuse Lighting Company, Syracuse, N. Y., has become associated with the Omaha Gas Company, Omaha, Neb.

Irwin H. Benny has resigned his position as superintendent with the A. H. Fox Gun Company, of Philadelphia, Pa., to accept a similar position with the Westinghouse Electric and Manufacturing Company, Lester, Pa.

Palmer St. Clair, formerly affiliated with the E. I. du Pont de Nemours and Company, City Point, Va., in the capacity of experimental engineer, has become identified with the Air Nitrates Corporation, of New York.

Philip M. Guba has resigned his position with the Jones and Laughlin Steel Company, Pittsburgh, Pa., to accept the position of New York sales manager for the Donner Steel Company.

George E. Hagemann, until recently instructor of mechanical engineering, University of Pennsylvania, Philadelphia, Pa., has become affiliated with the Warren Foundry and Machine Company, Phillipsburg, N. J., in the capacity of draftsman and engineer.

Robert H. Wallace has become associated with the Savage Arms Corporation, Utica, N. Y. He was formerly connected with the Alignum Products Company, South River, N. J., in the capacity of factory manager.

S. R. Hunter has resigned as superintendent of the gas-engine department of the Fairbanks Morse Manufacturing Company, Beloit, Wis., to become associated with the American Rolling Mill Company, Middletown, Ohio, as supervisor of production.

ANNOUNCEMENTS

D. W. Brunton, of Denver, Colo., has been elected a member of the U. S. Naval Consulting Board.

Major E. S. Lea, Ordnance Reserve Corps, has been relieved from duty at his own request, after having served for the last year as chief inspection officer of artillery ammunition, at the Frankford Arsenal, and will resume practice as a consulting engineer, specializing on artillery-ammunition inspection and production.

Harold B. Viedt has resigned his position as assistant superintendent of the radium extraction plant of the Radium Luminous Materials Corporation, Orange, N. J., and has entered the Officers' Training School for Steam Engineers, in the Naval Auxiliary Reserve, and is at present stationed at Pelham, N. Y.

Walter V. Turner, manager of engineering of the Westinghouse Air Brake Company, Wilmerding, Pa., has had the degree of Doctor of Engineering conferred upon him by the University of Pittsburgh, at their annual commencement, in recognition of his valuable services to the engineering profession and to humanity.

George M. Brill has recently resigned his commission as Major in the Ordnance Reserve Corps to take up the general matter of Requirements for the Emergency Fleet Corporation. He will continue to be located in Washington, since his duties necessitate the maintenance of a number of points of contact with other war activities, such as army, navy, railroad administration, allied purchasing, etc., in the joint study of all requirements for the purpose of avoiding interference and maintaining equilibrium between Supply and Demand.

Louis A. de Cazenove has assumed the duties of chief engineer of the National Tractor Company, and supervising engineer of the French American Constructive Company.

George F. Pettinos has severed his connections with the firm of Pettinos Brothers, Philadelphia, Pa., which he established in 1892, and is now in busines for himself, following the same lines of business, namely, foundry supplies, iron and steel, molding sands and gravel, and graphite, both foreign and domestic.

Harry C. Wootton has become associated with the Nordyke and Marmon Company, of Indianapolis, Ind.

Walter F. Wells, vice-president and general manager of the Edison Electric Illuminating Company of Brooklyn, has been elected president of the National Electric Light Association.

Tufts College has conferred the honorary degree of Doctor of Science upon **Major Ralph D. Mershon**, a member of the Naval Consulting Board and formerly assistant professor at Ohio State University.

Arthur B. Babbitt, who for the past six years has been head of the Department of Drawing and Design at Wentworth Institute, Boston, Mass., has resigned that position to become general manager of the Kent Machine Company, Kent, Ohio.

E. O. Estwing has resigned the position of management engineer with the Remington Typewriter Company, for a position as production manager with the Free Sewing Machine Company, Rockford, Ill.

Milton F. Flewelling, Jr., has resigned as chief draftsman of the Ashton Valve Company, Boston, Mass., and has enlisted in the United States Navy.

APPOINTMENTS

O. R. Randolph has been appointed engineer inspector for the State Corporation Commission of Virginia.

Harry Himelblau has been appointed representative of the Baltimore territory for the American Steam Conveyor Corporation.

E. Logan Hill, of New York, has been appointed secretary of the United States Shipping Board Commission on Port and Harbor Facilities. Mr. Hill was formerly assistant to the general manager of the Erie Railroad and affiliated lines, and was granted leave of absence from June 10 to serve on the above commission, which was appointed for the purpose of improving port and terminal facilities to the end that ships may be unloaded, repaired, bunkered and reloaded with the minimum loss of movement and time.

Prof. D. S. Kimball, of Cornell University, has been appointed acting president of Cornell University during the absence of President Schurman, who will shortly sail for France, where he will address the soldiers in the camps.

NECROLOGY

CAPTAIN OSCAR JOHN MAY

Oscar John May, Captain in the Signal Corps, United States Army, died on May 22, 1918, at the Washington Sanitarium, Takoma Park, Washington, D. C.

Captain May was born on May 15, 1878, in Chicago, Ill., and was educated in that city and graduated from the Lewis Institute. From 1900 to 1911 he worked with E. B. Ellicott, electrical engineer for the Sanitary District of Chicago, in various capacities—as operating engineer, constructing engineer and as superintendent of the Sanitary District Power House, Lockport, Ill. As superintendent he installed two of the 6000-hp. hydraulic turbines and generators with the necessary electrical equipment, having under his direction a large force of lubrication engineers for the development of advanced lubrication practice. He was next associated with the Texas Company, first as operating and testing engineer, and later as chief engineer of the Chicago district, supervising practical testing and research work on lubricants. In 1914 he was made assistant superintendent of the company and given charge of the designing and rearranging of mechanical conditions directly affected by lubrication.

Captain May entered the Service in June 1917 as a captain in the Engineers' Reserve Corps, and was recommissioned as a Captain in the Signal Corps in November 1917 and was assigned to the Lubrication Department. He had full charge of the experimental work necessary in the preparation of specifications covering lubricating oil for aeronautic engines, necessitating very elaborate tests at the Washington Navy Yard, where he had under his direction a corps of army and navy engineers. Very important work was also carried on under his personal supervision at the altitude testing laboratory of the Bureau of Standards, where in the first consecutive tests made Captain May stood continuously a watch of sixty-five hours, indicating his remarkable physical endurance and the tremendous interest and conscientious responsibility he felt in the work. He had full charge of the lubrication engineers and oil-house men recently established in the various aviation fields in this country, and also of the special experimental testing work in connection with lubricants and fuel at Dayton, Ohio, and at the various manufacturing plants.

As an indication of the appreciation of Captain May's ability and service he was recommended by the Chief of the Lubrication Department early in February for promotion to the rank of Major.

He was a member of the National Association of Stationary Engineers. He became a member of our Society in 1914.

MATTHEW ANDEN SYKES

Matthew A. Sykes was born on March 26, 1865, in Wallingford, Pa. His early education he obtained in the schools of Delaware County, Pa.; later he took several courses in the evening schools of Philadelphia. He was graduated from The Franklin Institute, his course there being in mechanical drawing.

Fom 1880 to 1890 Mr. Sykes worked with the Baldwin Locomotive Works, Philadelphia, where he first served his apprenticeship and was advanced to the position of contractor and then of foreman on production. For a short period in 1890 he was connected with the Midvale Steel Co., Philadelphia, as foreman in charge of the production work. He left this firm to take a position with Goodell & Waters Co., manufacturers of woodworking machinery in Philadelphia, where he directed the designing and making of tools and planned the work throughout the shop. In 1892 he became foreman with Bement, Miles Co., Philadelphia, and directed the building of special machinery. His next position was with the Sprague Electric Elevator Co., New York, as superintendent of their New York and Watsessing, N. J., plants and of construction on the installation of electric elevators. In 1896 he became superintendent of construction in the New York office of Morse, Williams & Co., Philadelphia, and installed all kinds of hydraulic, electric and belt-power elevators in the metropolitan district. The year 1897 to 1898 he spent with the Metropolitan Electrical Construction Co., on the installation of electric elevators in New York City. In 1898 he became associated with the Otis Elevator Co., New York, as assistant superintendent of construction, installing hydraulic and electric elevators, and for six months was superintendent of construction at the Pittsburgh office of the company. Mr. Sykes left the Otis Elevator Co. in 1905 to become superintendent of construction with the Standard Plunger Elevator Co., Worcester, Mass., of their New York and Toronto offices on the installation of plunger and electric elevators. After six years with this company he was for two years superintendent of construction of the Gurney Elevator Co., and for about a year with the Westinghouse Co., Schenectady, N. Y., as superintendent of their plant manufacturing agricultural machinery, grain separators, steam tractors, locomotive stokers, etc. In 1915 Mr. Sykes accepted a position with the Remington Arms Co., Eddystone, Pa., as superintendent of the division on production work of British rifles. At the time of his death he was superintendent of the erection shop of the Baldwin Locomotive Works, Eddystone, Pa.

Mr. Sykes became a member of the Society in 1917. He died on March 10, 1918.

GOLDWIN STARRETT

Goldwin Starrett was born on September 29, 1874, in Lawrence, Kan. He was graduated from the University of Michigan in 1894 with the degree of B. S. in mechanical engineering and spent the following four years in the office of D. H. Burnham, Chicago, Ill., architect, as architectural draftsman and assistant mechanical engineer. In 1898 he became superintendent and assistant manager in the New York office of the George A. Fuller Co., where he remained for about two years, leaving to take the position of secretary and assistant general manager of the Thompson-Starrett Co., New York. While with this firm he did a vast amount of mechanical work in the construction of commercial and office buildings. In 1904 Mr. Starrett became vice-president of the E. B. Ellis Granite Co., Northfield, Vt., which position he occupied for four years when he became the senior member of the architecural firm of Starrett & Van Vleck, designers of many large and important buildings in New York.

Mr. Starrett was a member of the American Institute of Architects and also of the Architectural League. He became a member of the Society in 1914. He died on May 9, 1918.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER AUG. 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate Member, those in the next class under Associate or Associate Member, those in the third class under Associate Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 82.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by Aug. 10, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about Aug. 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

NAGEL, THEODORE, Resident Engineer, Chemical Construction Co., Sheffield

Colorado

KNOWLES, RALPH R., Superintendent, Construction and Operation, The Ouray Consolidated & Reduction Co., Ouray

Connecticut

HALPIN, JAMES F., Superintendent, Tube and Rod Mills, Bridgeport Brass Co., Bridgeport

Illinois

GOTTSCHAL, CHRISTIAN M., Chief Designer, The Service Machine Corporation, Chicago

THALEG, OSCAR E., District Sales Manager, P. & M. Dept., Worthington Pump & Mchy. Corp., Chicago

PLAGWIT, ERIC, Treasurer and Secretary, The Heine Chimney Co., Chicago

WILLARD, DONALD E., Vice-President and Secretary, Decatur Malleable Iron Co., Decatur

Indiana

CLINE, BENJAMIN J., General Superintendent, Aeroplane Eng. Division, Nordyke & Marmon Co., Indianapolis

Maryland

DEDMAN, BRYANT, Engineer, Poole Engineering & Machine Co., Baltimore

Massachusetts

DOOLITTLE, FRED E., Superintendent, Knox Motors Company, Springfield

KIRMES, EDWIN W., Engineer with Walworth English Flett Co., Boston

LIVERMORE, JOSEPH P., Giving advice and testifying as mechanical expert in patent litigation, Boston

OSGOOD, HARRY E., Sales Engineer, Sanford Riley Stoker Co., Worcester

PICKELS, ROBERT F., Proprietor, Watts Regulator Co., Lawrence

PRARAY, CHARLES W., Mill Engineer and Architect, New Bedford

SAWTELL, WILLIAM H., Superintendent, Worcester Shock Absorber Co., Worcester

STETSON, GEORGE W., Sales Agent, Power Plant Equipment, Boston

WAITE, LORENZO E., General Superintendent of Becker Milling Mch. Co., Boston

WICKSTROM, HANS, Grinding Machinery Salesman, Norton Grinding Co., Worcester

Missouri

KEY, FRED, Vice-President and General Manager, Key Boiler Equipment Co., St. Louis

SOLOMON, CHARLES R., Chief Draftsman and Designer, United Iron Works Co., Kansas City

WISELOGEL, ROBERT F., Second Vice-President, John Nooter Boiler Works Co., St. Louis

New Hampshire

DOWNTON, CHARLES E., Employment Manager, The Atlantic Corporation, Portsmouth

New Jersey

FINKEN, WALTER S., Resident Engineer, Baker, Smith & Co., Morgan

MACARTHUR, DONALD, Manager, Seaboard By Product Coke Co., Jersey City

SNEDIKER, WALTER J. E., Manager, Ringwalt Linoleum Works, New Brunswick

TAYLOR, KNOX, President, Taylor-Wharton Iron & Steel Co., High Bridge

TRACY, HOMER D., Engineer, Robins Conveying Belt Co., River Edge

New York

CLARKE, VINCENT A., Special Engineer, Niles-Bement-Pond Co., New York

COTTON, HOWARD W., President, H. W. Cotton, Inc., New York

COZENS, ALFRED E., Outside Chief Engineer, Standard Shipbuilding Corp., Shooters Island

FREELAND, WILLARD E., Associate Editor, "The Iron Age," New York

GOBIN, ANDRÉ F., Mechanical Draftsman, U.S. Navy Yard, New York

HATCH, MELLEN C., Assistant to President, Locomotive Pulverized Fuel Co., New York

McCLELLAN, GEORGE F., Inspecting Engineer of public utility properties, Henry L. Doherty & Co., New York

MINER, ROBERT L., Assistant to General Superintendent, The Bossert Corp., Utica

PATTERSON, DUNCAN, Vice-President, Foamite Fire Extinguisher Co., New York

ROBERTS, WILLIAM E., Checker, Wilputte Coke Oven Corp., New York

RODEMEYER, HENRY, Superintendent, Cook Spring Co., New York

TRONELL, EDGAR R., Jr., New York Sales Manager, Spencer Heater Co., New York

VAN FLEET, HERMAN, Engineer in charge, Liquid Air Division, Air Nitrates Corp., New York

North Carolina

WHITE, GILBERT C., Consulting Engineer, Gilbert C. White, Durham

Ohio

SKINNER, ORAMEL H., Engineering Executive, Airplane Engineering Dept., Bureau of Aircraft Production, McCook Field, Dayton

Pennsylvania

BACH, GEORGE W., General Manager, Union Iron Works, Erie

BRAMWELL, JOSEPH W., Manager, Boston Office of American Bronze Corporation, Berwyn

McGINN, Michael J., Superintendent, American Insulation Co., Philadelphia

Washington

ABELL, ASHEL C., Assistant Professor of Mechanical Engineering, Washington State College, Pullman

Cuba

DALE, WILLIAM J., Chief Engineer in charge of Power Installations, Minas de Mathahambre, Pinar del Rio

Holland

VAN DIJK, JAN WILLEM, Dr., Managing Director of J. W. Brouwersplein 2, Amsterdam

India

AYEY, HARRY T., Professor, Ewing Christian College, Allahabad

Italy

DE LACOURT, ALBERTO F., Engineer, Conseil de la Societé Ansaldo, Genoa

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Connecticut

SCHLEIFER, NORMAN H., Secretary, Superintendent and General Manager, Meriden Press & Drop Co., Meriden

New York

SMITH, WILLIAM H. C., Sugar Machinery Engineer, Buyer, W. R. Grace & Co., New York

Pennsylvania

BARKLEY, JOHN F., Assistant Efficiency Engineer, Carnegie Steel Co., E. T. Works, Braddock

EBY, SAMUEL E., Master Mechanic, American Steel Films, care of Thurlow Works, Chester

HEIMPEL, EARL F., Assistant M. M. of Rolling Mill, Bethlehem Steel Corp., Bethlehem

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

California

KITSON, FRANK C., Junior Engineer with the U.S. Shipping Board, Emergency Fleet Corporation, San Francisco

Connecticut
GLEDHILL, THOMAS, Foreman Dept. M.E.T.L., Remington Arms U.M.C. Co., Inc., Bridgeport

Illinois
NEWTON, LEONARD V., Supervision of Equipment, The Texas Co., Chicago
MADISON, RICHARD D., Chief Draftsman, Indianapolis Office, Ordnance Engineering Bureau, Indianapolis

Maryland
BUSTOS, ENRIQUE, Assistant Engineer, Mechanical Engineer, Baltimore Copper Works, Baltimore

Massachusetts
ARMOUR, WILLIAM W., Vice-President and Superintendent of Armour's Pattern Shop Co., Worcester
STEVENS, HAROLD F., School Teacher, Junior Master, Hyde Park High School, Hyde Park

New York
BEWLEY, WILLIAM E., Manager, Inter-Continental Machinery Corporation, New York
CALDWELL, WILLIAM E., Chemist, The United Electric Light & Power Co., New York
FELLOWS, OLIN B., Vice-President, Ideal Wrapping Machine Co., Middletown

Pennsylvania
PRUDDEN, THEODORE M., First Lieutenant, Ordnance Department, R.C., Frankford Arsenal, Philadelphia
SLEEMAN, EARL C., Chief Draftsman, Monessen Plant, Pittsburgh Steel Products Co., Monessen

Wisconsin
KNOCKE, LOUIS T., Testing Engineer, Waukesba Motor Co., Waukesha

FOR CONSIDERATION AS JUNIOR

Alabama
HARTLEY, ALBERT O., Special Engineering work for Capt. C. G. Landes, U.S. Nitrate Plant, No. 1, Sheffield

Colorado
JOHNSON, EDWIN C., Student graduate Colorado Agricultural College, Denver

Connecticut
BISHOP, WILLIAM R., Junior Engineer, Gage Dept., Remington Arms,
McKEON, E. JAMES, Designing Draftsman, Remington Arms Co., Bridgeport
MOORE, HENRY H., Tool designer, Liberty Ordnance Co., Bridgeport

District of Columbia
EICHLER, EDWARD, Aeronautical Designer, Bureau of Construction & Repair, Navy Dept., Washington

Illinois
VONACHEN, FRANK J., 2d Lieutenant, Ordnance Dept., N.A., Rock Island Arsenal, Rock Island

New York

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT POSITIONS

Stamps should be inclosed for transmittal of applications to advertisers; non-members should accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

Members applying in person for Government positions at such places as Navy Yards should invariably make appointments beforehand by letter, telephone or telegraph, and arrange to have passes or the equivalents so that they can gain entrance. In this way they will avoid disappointment.

TECHNICAL WRITERS to visit colleges and technical schools and write up courses to be used by the Government in the training of about 90,000 men during the coming summer months. 2620.

HIGH-GRADE EXECUTIVE for ship-construction plant in the South; capable of assuming responsibility for oversight of new construction both for wood and cement ships and supervision of the operation of the property under the direction of a president or general manager. Company is prepared to pay generous salary to right man and will consider giving him an interest in the property if he demonstrates his ability. 2621-A.

ASSISTANT to the above executive. 2621-B.

STATISTICIAN for Fuel Administration to keep records of events in Washington, to design and organize the Statistics Department for his work, to keep records of State operations and present these facts graphically. Location, Washington. 2622.

FOUR MEN FOR FUEL ADMINISTRATION; technical education not essential; of pronounced executive ability to take charge of a group of five States and report their affairs to Washington. 2623.

SUBMARINE FORCE, U. S. NAVY. It is desired to call the attention of young men who have had technical training and experience to the fact that their abilities can best be put at the service of the country by selecting a branch of service in which their special qualifications will be of the greatest use.

The Submarine Force of the United States Navy requires the services, as officers on board submarines, of young men who have had technical training in mechanical and electrical engineering and who have had experience in these professions. It is intended to enroll a number of such men as provisional ensigns in the Naval Reserve Force, give them a course of instruction in deck duties at Annapolis and a course in submarine work at New London. Those who successfully pass these courses will then be sent on board submarines for regular duty.

It is requested that any men who desire this duty and who are qualified as below outlined send their names and addresses to

c/o Commander Submarine Force, U. S. S. *Chicago*, care of Postmaster, New York.

Qualifications required: Desire to serve in submarines; degree of M.E., E.E., or E.M.; two and a half years of practical experience in profession; not over 35 years old; physically strong and sound.

Candidates should, if practicable, receive the indorsement of one of the following organizations: Naval Consulting Board; National Research Council; American Society of Mechanical Engineers; American Institute of Electrical Engineers; American Institute of Mining Engineers.

Conant Taylor,
Lieutenant-Commander, U. S. Navy,
Senior Member.

By direction Commander Submarine Force, U. S. Atlantic Fleet. 2624.

CIVILIAN POSITIONS

MECHANICAL ENGINEER for large eastern Massachusetts company, as assistant in physical testing laboratory, competent to take entire charge of this work at an early date. Man of good personality and diplomacy, as part of his work will be investigating conditions in outside plants offering recommendations as to the proper adaptation of our product and assisting salesmen with the bigger propositions. Salary commensurate with experience and demonstrated ability. 0358-G.

DRAFTSMEN, general and mechanical with structural experience. Salary, $135. Location, New Jersey. 0359-G.

SALESMAN on sugar machinery. Expert in operation. Location, Tukaman, Argentine, South America. Salary, $5,000. 0360-G.

ONE MECHANICAL AND ONE ELECTRICAL ENGINEER, preferably married men without children, for positions at sulphur refining factories at Marseilles and Cette, France. Men able to transact business in French. No one with German blood or connections need apply. 0361-G.

INSTRUCTOR in mechanical drawing and possibly some mathematics, for a University on Pacific Coast. Work to begin about the first of October. Salary, $1,200. 0362-G.

ASSISTANT TO GENERAL MANAGER. Must have shop and office experience; preference given to applicant experienced in scientific management methods or in manufacture of paper or its products. State experience, references, age, salary, and when available. Location, New England. 0363-G.

SALES ENGINEERS, men familiar with furnace and boiler operation and refractories to handle high-grade furnace specialties; fine opportunity for right man. Location, Eastern or Middle Pennsylvania, New York State, Connecticut or Indiana. Salary and commission. 0364-G.

INSTRUCTOR IN MECHANICAL ENGINEERING in recently established department of well known University. College graduate with some experience in machine design or with internal-combustion engines desired. Salary depends on man engaged. Location, Maryland. 0365-G.

DRAFTSMEN to work out surveyor's maps. Location, New Jersey. Salary depends on man. 0366-G.

YOUNG ENGINEERS FOR OFFICE OF CONSULTING ENGINEER in Pittsburgh; office work, operation and investigation of public utilities. Salary $20 to start. 0367-G.

MATERIAL CHECKERS, young men to check up material for shipment and on receipt at plant, follow distribution to proper departments. Location, Alabama. Salary about $125 a month. 0368-G.

DRAFTSMEN, checkers on industrial plant layouts, elevating and conveying machinery, piping, etc. Headquarters, New York. Salary $30 to $40. 0370-G.

INSPECTORS accustomed to receiving engineering material. Salary $125. Headquarters, Plant at Muscle Shoals, Alabama. 0371-G.

SUPERINTENDENT, man with executive experience capable of handling mechanics. Location, Niagara Falls, N. Y. Salary, $350. 0372-G.

FILE CLERK, to have charge of files, record of blue prints, distribution and filing. Salary $30. Headquarters, New York. 0373-G.

FILE CLERK FOR DRAFTING ROOM RECORDS. Salary $25. Headquarters, New York. 0374-G.

MECHANICAL ENGINEER, technical graduate with chemical laboratory experience, if possible. Salary, $150. Location, New York. 0375-G.

MECHANICAL DRAFTSMAN, preferably one with experience in hydraulic machinery. Salary depends on man. Headquarters, New York. 0376-G.

DRAFTSMEN, experienced in power-house design and equipment, also foundation and structural works. State age, nationality, and salary expected. Location, New York. 0377-G.

TESTERS AND INVESTIGATORS for large New York company. Work on gas-fired boilers, gas engines, gas heaters, etc. Salary, $20 to $25. 0378-G.

INSTRUCTOR in machine design. Opening in Eastern Institution for M. E. graduate with two or three years' experience on machine design. Give full record. 0379-G.

INSPECTOR OF MECHANICAL AND ELECTRICAL EQUIPMENT. Technical graduate preferred. Salary, $110 to $120. 0381-G.

DRAFTSMEN on power-house layout, and piping. Salary depends on man. Location, New York. 0382-G.

TECHNICAL GRADUATE, man over 30 years of age for estimating and engineering work in general sales department of concern manufacturing large power plant equipment. Salary depends on man. Location, New York City. 0383-G.

DRAFTSMAN on marine-engine work in factory having large Government contract. Permanent employment for right man. One having oil-engine experience preferred. Location, New York State. 0384-G.

DESIGNER, mechanical engineer for work in connection with development of new chemical plant. Knowledge of chemical industry valuable. Location, Philadelphia. 0385-G.

SHIPBUILDING DRAFTSMEN. Salary, $35 to $40. Location, Brooklyn, N. Y. 0386-G.

SALES ENGINEER, 24 to 25 years old, exempt or class 4. Good appearance and personality; energetic and willing to work. Must have initiative and be a thinker. College degree and one year shop work on telephone or electrical equipment; or high school education and two or three years shop work as above. Location, New York to travel. Salary about $1,500 to $1,800. 0389-G.

ENGINEERING EDITOR, with mechanical engineering education, some appreciation of the economic side of engineering and some insight into shop management, a liking for writing; good address, and if possible, so-called mixing qualities. Age preferably between 30 and 40 years. Salary depends on his measuring up to these specifications, his experience, and the time needed to make him a producer. He is wanted for one of the most important positions on Engineering Journal of enviable reputation, and his progress will be dependent solely on his ability to make good. 0390-G.

ESTIMATOR wanted by firm doing high grade of work and which offers possibilities of developing to assistant in charge of the department where all estimating work is done. Requires knowledge of general building construction. Location, New York. 0391-G.

MASTER MECHANIC OR PLANT ENGINEER, technical graduate with engineering ability, who has had practical experience along these lines. Location, New Jersey. Salary, $2,500 to $3,000. 0392-G.

DRAFTSMEN on power plants. Location, New York. Salary, $140. 0394-G.

TOPOGRAPHICAL DRAFTSMAN wanted by New York City firm. 0395-G.

MAINTENANCE ENGINEER to take care of all piping and pipe line in plant. 0396-G.

INSPECTOR PIPE COVERING. Salary about $200. 0397-G.

MASTER MECHANIC, with experience in handling men and in repair maintenance and up-keep of mechanical equipment used in chemical plants. 0399-G.

PRODUCTION ENGINEERS for staff of firm located in New York City. 0401-G.

CHIEF ELECTRICAL ENGINEER, experienced in repair and maintenance of electrical equipment. Salary $3,000 to $3,600. Headquarters, Alabama. 0404-G.

TWO MECHANICAL ENGINEERS, with civil-engineering experience if possible, in maintenance of cement, fertilizing and chemical plants, including roads, sewer, water-gas, steam and air lines all sizes and pressures. 0405-G.

FOUR ASSISTANT MASTER MECHANICS, experienced in repair work, maintenance, operation and equipment, as used in cement, fertilizing and chemical plants. Location, Alabama. 0406-G.

TEN FOREMEN familiar with mechanical piping, electrical work, blacksmithing, welding, structural steel, sheet metal, etc., having experience in charge of shops. 0407-G.

COMBUSTION ENGINEER, man familiar with fuel problems, sampling coal, able to make researches, determinations of product, and to handle sampling force of five men. Salary depends upon man. 0409-G.

FOREMAN for sampling department. 0408-G.

COST CLERK to estimate on costs of equipment, appraisal work, etc. Location, Alabama. Salary, $130 to $160. 0410-G.

OFFICE EXECUTIVE for office-cost department, having charge of crane and other machine costs, preparing these for use of sales department in making their estimates and proposals. Man must be steady, reliable, and preferably married. Good accountant and must possess sufficient executive ability to direct four or five others under him and get out the work assigned to him; will be expected to work himself and get into the details of this department. Location, Michigan. 0411-G.

TURBINE MAINTENANCE ENGINEER, man for inspection of turbine and auxiliary equipment and taking charge of the major repairs to apparatus for large power company operating several stations. One with experience with Westinghouse turbine preferred. Location Pennsylvania. 0413-G.

BOILER MAINTENANCE ENGINEER, man for inspection of boilers and boiler-room apparatus. One with construction experience in large boilers preferred. Location, Pennsylvania. 0413-G.

MASTER MECHANIC for large power plant; experienced in repairs and maintenance of large turbo-generators and boilers. Location, Pennsylvania. 0414-G.

ENGINEER to take charge of large generating station, consisting of three 10-kw. General Electric turbo-generators with 8 Stirling boilers equipped with Coxe traveling stokers for burning small sizes of anthracite fuel. Plant has three shifts of 8 hr. each and employs about 100 men. Man to take charge of this station should have considerable executive ability as well as general operating knowledge. Location Pennsylvania. Salary $3500 to $4000. 0415-G.

SUPERINTENDENT for growing concern having machine shop, foundry, pattern shop and blacksmith shop, just starting on attractive specialty, requiring capable superintendent experienced in above lines, and a good systematizer. Excellent opportunity for a young man. Location Michigan. 0417-G.

ASSISTANT ESTIMATOR, man able to take off accurate quantities for mechanical equipment from engineers' drawings, and have fair idea of cost of various machine-shop operations, pattern making, and the installation of steam lines, shafting and general mill equipment. Position will probably last from 1½ to 2 years with good opening later on for capable man. For first few weeks he would be required to help on the quantities for reinforced-concrete buildings, etc. Location Ontario, Canada. Salary $130 to $150 to start. 0418-G.

FIELD INSPECTORS wanted on electrical, plumbing and drainage work. 0419-G.

ENGINEER-DESIGNER on reinforced concrete, light steel construction. Salary $250 up. 0420-G.

DRAFTSMAN of conveying machinery. Salary depends on man. Location New York. 0421-G.

YOUNG TECHNICAL MEN with a few years of practical experience, preferably along executive lines; men with good common sense and tact. Opportunities are innumerable and a good man has chance to advance rapidly. Location Virginia. Salary $150 to $200. 0422-G.

MARINE DRAFTSMEN in connection with piping layouts and machinery arrangements. Location Pennsylvania. Salary according to qualifications. 0423-G.

LABORATORY ASSISTANT in instrument and standardizing laboratory for men of technical ability to carry out research work. Location Massachusetts. 0424-G.

CONSTRUCTION, ARCHITECTURAL and MECHANICAL DRAFTSMEN wanted for Government work connected with the ship-construction program at Philadelphia. Also SQUAD CHIEFS and SPECIFICATION WRITERS. 0425-G.

TECHNICAL GRADUATE with considerable practical training and experience. Man abreast of the times, with respect to the developments in the design and application of machinery; capable of supervising the design and manufacture of special tools and equipment; up-to-date in modern machine-shop practices and who possesses executive ability of a high order. Age 35 to 38 years. Location New York State. 0428-G.

POWER PLANT ENGINEER, must be familiar with modern boiler-room practice. Location Pennsylvania. 0429-G.

MECHANICAL DRAFTSMEN on Government Shipyard work near Philadelphia.

CONSTRUCTION ARCHITECTURAL DRAFTSMEN on heavy steel and concrete work. State salary expected, age, experience, and when available. 0430-G.

PRODUCTION ENGINEER for concern manufacturing gages, fixtures and cutters to speed up deliveries of shop doing war work. Give past experience and salary expected. 0431-G.

INSTRUCTOR in mechanical engineering, to teach descriptive geometry, machine drawing, some laboratory work, and elementary steam engineering. Salary $1500 per year. Location Ohio. 0433-G.

YOUNG MAN not subject to draft in very near future. Mechanical training not necessary, but must have a fair knowledge of drafting. Immediate chance of advancement. Salary $75 to $100 per month to start. 0436-G.

CIVIL ENGINEER with knowledge of mechanics; good instrument man experienced in the execution of plans, laying out buildings, following out plan work, concrete work, construction, steel work, trestles, etc. Should be able to follow construction of bridges, sewers, roads and mill machinery. Location Canada. 0437-G.

ENGINEER IN CHARGE OF DIVISION OF CONSTRUCTION AND DESIGN for New York office of chemical plant. 0438-G.

ASSISTANT PURCHASING AGENT for chemical plant in New York City. Some travelling. 0439-G.

PRODUCTION MANAGER familiar with, and experienced in factory production. Location Alabama. 0440-G.

EXECUTIVE REPRESENTATIVE. Man to attend to affairs in Washington and report back to head office. 0441-G.

GENERAL CONSTRUCTION ENGINEER AND EXECUTIVE wanted as general assistant to the resident manager. Salary $7500. Location Alabama. 0446-G.

OFFICE MANAGER for resident manager in the field. Salary $3000. Location Alabama. 0447-G.

GENERAL CONSTRUCTION AND EQUIPMENT ENGINEERS on staff of resident manager. Works or equipment engineer, no chemistry necessary. Salary $2400 to $3600. 0448-G.

ASSISTANT SUPERINTENDENT of construction of coal, lime and coke plant. Salary $225. Location Alabama. 0449-G.

ASSISTANT SUPERINTENDENT of construction of carbide and lime-nitrogen plants. Salary $225. Location Alabama. 0450-G.

ASSISTANT SUPERINTENDENT of construction on liquid-air plant. Man familiar with erecting air compressors, high-pressure piping, etc. No technical knowledge of liquid-air works required. Salary $225. Location Alabama. 0451-G.

ASSISTANT SUPERINTENDENT of construction of nitrate plant. Some knowledge of nitrate plants and equipment desirable, but not essential. Salary $225 Location Alabama. 0452-G.

ASSISTANT SUPERINTENDENT of construction of nitric-acid plant. A comprehensive knowledge of nitric-acid work highly desirable, and a fair working acquaintance essential. Salary $225. Location Alabama. 0453-G.

ELECTRICAL AND MECHANICAL ENGINEERS for plant-layout work. Temporary employment. Location New Jersey. 0454-G.

TESTS ENGINEER, man experienced in the operation of boilers, engines, etc. Work covers testing and investigations in steel mills in western Pennsylvania, Ohio, West Virginia, and Indiana. 0455-G.

PRODUCTION ENGINEER for large established New England manufacturer of mechanics' hand tools; high-grade man with executive qualifications. Must be technical graduate with successful factory and labor experience, possess initiative and be familiar with modern methods of producing mechanics' hand tools and kindred products under favorable and profitable conditions, and generally competent to meet with diplomacy all wage and product problems. Man of 35 to 40 years of age preferred State age, experience, salary expected, and when available. 0456-G.

DRAFTSMAN, 19 to 30 years of age; man who can think as well as work; the more education the better. A few years' training, preferably in shop and drawing room on medium or heavy machinery. No instrument makers or electricians wanted Location, Newark, N. J. Salary about $100. 0388-G.

DETAIL EQUIPMENT SUPERINTENDENT for carbolite furnaces and electrode shop. Maximum salary $250. 0398-G.

TESTS ENGINEER, 25 to 38 years old, aggressive, analytical mind, worker Complete technical foundation, college graduate. Must be trained in responsible engineering work, preferably along testing and research lines, either mechanical or electrical. Location Newark, N. J. Salary about $200. 0387-G.

MECHANICAL-LABORATORY ASSISTANTS and DRAFTSMEN required for important war work in development of parts for sheet metal, fabric and rubber. Graduates from manual-training schools with one or two years' shop experience or one or two years in an engineering school. Enclose photograph, state age, give references, position in draft and willingness to enlist or be induced in the army for work of this nature. 0459-G.

[illegible] AVAILABLE

[illegible] society are listed in [illegible] the [illegible] band by the 12th of [illegible] should be [illegible] cards indicate the [illegible] not repeated in [illegible]

MECHANICAL ENGINEER, age 34, married, college graduate, 15 years experience, employed [illegible] seeking for greater possibilities than present position offers. Will be glad to consider one requiring initiative and organization ability along executive lines. Correspondence with firms desiring to be represented in Washington especially invited. G-177.

EXECUTIVE ENGINEER SALES OR DISTRICT MANAGER. Eastern territory preferred account of large acquaintance here. 12 years experience handling power-plant equipment and power-transmission machinery. Graduate mechanical engineer, can show record as to results and ability to get business; ten years in last position with concern of national reputation. G-178.

MECHANICAL ENGINEER, Member, technical graduate, age 39, desires position as engineer or chief draftsman. Expert in design of high-power hydraulic turbines, governors, etc., also shop practice, layout of power plants and design of general machinery. One year's experience in a testing laboratory for machinery and material. G-179.

ASSISTANT TO PRESIDENT OR GENERAL MANAGER of a manufacturing company desired by a resourceful and successful executive mechanical engineer with broad industrial experience in factory layouts, equipment and management. Complete record on request. G-180.

PRODUCTION OR PRODUCTION EQUIPMENT ENGINEER, mechanical superintendent or assistant or other responsible position on either designing or manufacturing end or both. Must be war work. Salary about $4000. Would like to correspond with party needing self-starting man for above positions. Have successfully held them and am also practical mechanic and designer. Experience covers originating, designing, building and operating numerous special and standard automatic and semi-automatic machines for producing a wide variety of articles from wire, sheet metals, paper, wood, etc., for assembling, labor saving, processing, conveying, cost reducing, etc. Punches and dies, jigs, fixtures and tools and general engineering. Also routing, cost accounting, bookkeeping, time study and production. Will finish contract on non-essential work and be available shortly. Prefer place where the position is big and difficult and with after-the-war prospects. Am an American, 28 years old, married with family, draft exempted. Will go anywhere. G-181.

EXECUTIVE ENGINEER; American; 35 years of age, married; University graduate; general engineering experience; four years electrical and mechanical consulting office, one year construction draftsman, four years chief designing engineer for large public utility holding corporation in charge of design, materials and construction. At present employed as assistant works engineer [illegible]. Easily adaptable to con[illegible] and ambitious. Will con[illegible] reliable [illegible] in [illegible] organization. Central location preferred. G-182.

MECHANICAL [illegible], Junior Member, age 28, [illegible] draft. Technical graduate with [illegible] experience along mechanical and [illegible] lines in manufacturing and [illegible] a large manufacturing plant. [illegible] position offering good opportunities [illegible] preferably located in Chicago or the Middle West. G-183.

A COMPETENT FOUNDRY MAN will be available June 1. Capable of handling any foundry position; has had vast experience in handling complicated foundry work and can give satisfactory reasons for wanting to change position. G-184.

EXPERT INDUSTRIAL EDUCATION AND SAFETY ENGINEER. Graduate Massachusetts Institute of Technology, mechanical engineering, 1911, 29 years of age, married, in Class IV of the draft. Have three and a half years' experience as factory inspector, fire protection and safety engineer. For last four years have had charge of all day and evening industrial education for men and boys in largest manufacturing state in the country. Can furnish highest credentials. Desire position of greater responsibility. Salary $3500 or over. Location in New England preferred. G-185.

ASSOCIATE MEMBER, with 20 years' experience in designing, constructing and operating power plants, sub-stations, pumping plants, factories, gas-producer plants, etc., also extensive experience designing and constructing electric railway and floating equipment, will be open for engagement about June 15. Competent to assume full charge and to produce results. No objections to office or drafting work. G-186.

SALES AGENT, mechanical engineer, technical graduate, 13 years' experience in selling, designing and estimating, desires to represent high-class manufacturer in New England territory with headquarters in Boston. Best of references. G-187.

EXECUTIVE OR PURCHASING ENGINEER in touch with largest manufacturers of mechanical, electrical equipment and sources of engineering materials; presently engaged along these lines. Wishes connection with opportunities for greater activity. G-188.

MECHANICAL ADVISER AND DEVELOPMENT ENGINEER. Special machine designer, policy investigator, practical and technical education, good organizer and systematizer. Specialist on mechanical efficiency operation. Expert on substituting mechanical devices for hand labor. Past 15 years specializing on designing, developing and manufacturing up-to-date cost-cutting appliances, special equipment, tools and labor-saving devices for manufacturing special product efficiently. Age 35. Associate member. Salary $4800. Desire new connections with large corporation contemplating improving or redesigning its present manufacturing methods where above experience is essential. Location vicinity Newark or New York City. G-189.

MECHANICAL, ELECTRICAL ENGINEER. American, 14 years' practical and theoretical experience in manufacture of engineering specialties, machine tools, shop equipment, power, machinery and shop maintenance, oxy-acetylene, drafting, physical and experimental testing, shop welfare and power-house work. An executive with initiative and aggressiveness. At present employed. Location immaterial. Salary $2800 and expenses. G-190.

EXECUTIVE MANAGER, Member, with experience in designing, manufacturing, installing, estimating and selling of electric, pneumatic and mechanical apparatus. Experienced in the investigation of unsatisfactory methods and conditions and capable of devising and executing efficient remedies. New York or vicinity preferred. G-191.

GRADUATE ENGINEER, with ten years' active and consistent experience in the practice of principles of industrial management; is not an efficiency engineer or cost clerk. Will associate himself with a bank as industrial expert or with large manufacturing enterprise as confidential assistant to president or manager, or will take charge of an executive department but not below works manager. Available July 1. G-192.

EXECUTIVE, MECHANICAL, and ELECTRICAL ENGINEER. Strong technical man on power and power equipment. Has had 12 years' operating and construction experience with large public-utility and manufacturing companies. An exceptional man for a manufacturing or operating company. 35 years of age, and married. G-193.

SALES ENGINEER, mechanical engineering graduate, two years' experience, desires to get in touch with manufacturer in Middle West, having opening in office or in outside work. No continuous traveling desired. Experience in air-compressor work and heat-treatment of metals. Salary $200 jer month. G-194.

GENERAL MANAGER. Graduate mechanical engineer, 40 years old member, at present engaged, desires opening as general manager of manufacturing company in which he can obtain an interest. New England preferred. Twenty years' experience in manufacturing heavy and light machinery, selling and management. G-195.

MECHANICAL ENGINEER, now chief engineer of small concern, desires position with medium or large concern as chief draftsman, head of development work, or other executive position. Experience in general engineering, automatic machinery and machine tools, hydraulic machinery, rubber celluloid manufacture, electrical heating for industrial purposes, quantity manufacture, system and organization generally; some airplane experience. New York, Newark and vicinity preferred. Salary not under $3000. G-196.

MEMBER with broad business and engineering experience here and abroad, American, 45; fully conversant with the principal languages; knowledge of purchasing and selling; tactful in handling of men; at present employed as designer of special plant. Desires change by September 1, preferably to supervise work, inspect or represent, or act as assistant to executive where responsibility is required. To start, $4000. G-197.

EXECUTIVE MECHANICAL ENGINEER, member of leading professional societies, important war committees and commissions, degrees, author, American, employed on technical research and development work in non-essentials; special ability, mechanical invention, simplification of design, cheapening and elimination of manufacturing operations, industrial-plant operation, cost reduction, etc.; seeks more war-essential duties. Usefulness first, salary secondary consideration. G-198.

EXECUTIVE OR ASSISTANT. Cornell M. E., with nine years' practical experience in shipyard, machine shop, and general heavy and medium work. Capable of directing work and men with maximum production and minimum friction. Capable and thorough organizer, familiar with manufacturing details. Salary at least $2800. G-199.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

Evolution of the Aircraft Engine

THE War Department authorizes the following statement of evolution in aircraft engines prepared by the National Advisory Committee for Aeronautics:

The first man-carrying airplane flights were made in December 1903, with the Wright Bros.' engine, developing 12 hp. and weighing 152 lb., or 12.7 lb. per hp. In 1910, seven years later, the average horsepower of aeronautic engines had increased to 54 and the weight decreased to 5.7 lb. per. hp. In another seven years, 1917, the average power output had advanced to 243 hp. and the weight decreased to 2.8 lb. per hp. In March 1918 the Liberty 12 developed 432 hp. for a weight of 808 lb., or 1.86 lb. per hp. At the present time (May 1918) the Liberty 12 is yielding a maximum of 450 hp. for a weight of 825 lb., or 1.83 lb. per hp.

Advance in Ratio. The accompanying table shows the advance in the average power-weight ratio by years for the engines in actual flying use. It is to be especially noted that the Langley-Manly engine, built in 1901, was 9 years ahead of its time in the matter of power output, and 16 years ahead in its weight per horsepower.

In 1917 the Liberty 12 was 65 per cent more powerful and 28 per cent lighter per horsepower than the average in service for that year. So far this year these figures are probably changed to 50 per cent and 25 per cent, respectively, which indicate the advance of the Liberty over the average engine in service at the present time.

AIRCRAFT-ENGINE EVOLUTION

	Year	Horse-power	Weight, lb.	Weight per horse-power, lb.
Langley-Manly engine	1901	52	151	2.9
Original Wright Bros.	1903	12	152	12.7
Improved Wright Bros	1904	16	180	11.4
Improved Wright Bros.	1905	19	180	9.5
Redesigned Wright Bros.	1908	35	182	5.5
Average on market	1910	54	309	5.7
Wolseley engine	1913	147	720	4.9
Average on market	1914	112	437	3.9
Average on market	1915	133	512	3.8
Average on market	1916	185	570	3.1
Average on market	1917	243	693	2.8
Liberty 12-cylinder	1917	400	801	2.0
Liberty 12-cylinder (March)	1918	432	808	1.9
Liberty 12-cylinder (May)	1918	450	825	1.8

Consumption of Fuel. The average consumption of fuel decreased from about 0.8 lb. per hp-hr. in 1903 to about 0.65 lb. in 1914, since which it has slowly dropped to 0.55 lb. in 1918, and for the Liberty to 0.50 lb. The present Liberty consumption is approximately 0.46 lb. per hp-hr.

Illustrating the advance made, the Wolseley Co. in 1913 could only obtain 147 hp. at 1400 r.p.m. from eight cylinders, 5 in. bore by 7 in. stroke, or 18.375 hp. per cylinder. This is the same size cylinder as used in the Liberty, which now gives 450 hp., at 1800 revolutions, from 12 cylinders, or 37.5 hp. per cylinder, which is double the power per cylinder obtained in the Wolseley. Even if we reduce the Liberty results to the same speed as the Wolseley—that is, 1400 revolutions—the Liberty still represents a great advance, for at that speed 350 hp. are developed, or 29.2 hp. per cylinder. Moreover, the Wolseley weighed 4.9 lb. per hp. as compared with 2.3 for the Liberty at the same speed, or 1400 r.p.m. (*The Official Bulletin*, June 12, 1918, p. 16.)

International Aircraft Standards

As has been previously stated in THE JOURNAL, an American commission has recently been sent to Europe, where it spent several weeks in conference with engineering representatives of the Allies on the formulation of specifications of materials, mounting and dimensions of parts for aircraft and automotive apparatus generally.

The general feeling is that these conferences have constituted a real advance and facilitated ultimate international standardization. A formal international conference was held in London with representatives of France, Italy, Great Britain and the United States being present. A number of less formal sessions and conferences were held in various places, and many factories, repair stations, laboratories, etc., were visited.

The prime objects of the conferences were to facilitate the sending of most usable supplies to England, France and Italy from the United States, and also to arrange so as to have parts, fittings and instruments made interchangeable on aircraft produced in the different countries.

Progress was made at the conference abroad in the formulation of Allied standard specifications for aircraft steels, using the current American, British, French and Italian specifications as a basis, covering both the general procedure for testing and the chemical and physical requirements of wrought steels.

In the metric sizes the S.A.E. and the British ball-bearing series are identical, except that six S.A.E. sizes have not been included in the British list. A revision of tolerances and limits recommended by the British and the American delegates is under consideration. Limits of eccentricity in radial bearings and outside dimensions of thrust bearings were other subjects of study.

The 18-mm. spark plug, incorporating the best features of the British and the S.A.E. plugs, has been recommended for use on American and British stationary-cylinder and rotary engines. Practically the same plugs are used in France and Italy.

The dimension specifications for British and for American magnetos are substantially the same, with the exception of one dimension of magneto space. The American specification of the taper as one in five is the same as the British specification of the taper as one in ten, owing to the fact that the British refer to the slope of the conical surface to the axis.

The plan, provisionally adopted by the subcommittee of the International Commission on Pipe Threads, which met in Paris, July 1914, for a standard method of designating units of construction, was discussed, with reference particularly to screw threads and gear-wheel teeth, the idea being to seek

a unit which could be used with either the inch or the metric system is employed. Taking screw threads as an illustration, a system of notation was outlined by which each screw would bear a distinctive number based on the diameter in eighths of an inch, and the pitch in the number of threads per inch or per 127 mm. (= 5 in.), without reference to the unit in which the measurement might be made. For example, a $\frac{3}{4}$-in. U. S. standard bolt having 10 threads per inch would be designated a "6 x 50" bolt in countries using the metric system. The selection 127 mm. as the length over which the number of threads should be stated in countries using the metric system is based on the fact that this gives *whole* number of turns, these being five times the number of threads per inch.

The very difficult problem of bringing together the advocates of the metric and of the inch bases is in abeyance, but it is felt by some that the plan outlined above may afford the first step.

The practices in the preparation and use of glue are much the same in the United States and Great Britain. Mechanical methods of application and electrical method of heating are used largely here, but neither of these methods is common in England. Comparative tests of British and American methods of testing glue are being made.

The question of spruce supply was naturally discussed. Kiln procedure has been simplified, the results being satisfactory almost invariably. It is appreciated by all that the splicing of wood is an important subject. Additional approved designs of laminated and box spars will be recommended.

Propeller-hub and fittings practice will be further unified so far as shall prove advisable and possible.

Coördination of water and fuel piping standards is largely dependent on thread practice. The use of outside dimension only for nominal diameters of metal tubing has been recommended by the British and the American committees.

The British and American practice in wheels and tires are substantially in accord. Discussion is being had as to the advisability of extending the list of wheel sizes which has been adopted here.

The number of tire sizes will be kept to the lowest possible minimum.

The British and the American steel wire cables are sufficiently alike to be practically interchangeable. The same thing is true of high-tension steel wire.

It is felt that similarity of design is not necessary in turnbuckles, satisfactory interchangeability being securable if the fork-end and pin dimensions are standardized

The single aim in considering the various matters is to ascertain to what extent we can, without interfering with our productive capacity, adopt European standards with advantage; to what extent we can assist more effectively in cases of European conformity with our practices; following the course that will bring the best results. That which does not contribute to the winning of the war is of quite secondary importance. Anything that does contribute to the winning of the war is obviously of prime importance. (Abstract of a paper presented by Coker F. Clarkson before the *Society of Automotive Engineers*).

Standard Heavy-Duty Motor Truck Adopted by War Department

The following statement is authorized by the War Department:

One of the questions of standardization of motor transportation for use of the Army has been settled by the Secretary of War, i.e., the quartermaster standard type B truck has been officially adopted as the standard heavy-duty cargo truck for use of the Army in all its departments requiring this capacity truck. A large number of these trucks are now on order, and it is expected that the first 10,000 of these will be completed on or about August 1, 1918. (*Official Bulletin*, June 7, 1918, p. 8)

The Liberty Engine Described in Detail

The War Department authorizes the following statement:

The designs of the parts of the Liberty engine were based on the following:

Cylinders. The designers of the cylinders for the Liberty engine followed the practice used in the German Mercedes, English Rolls-Royce, French Lorraine-Dietrich, and Italian Isotta Fraschini before the war and during the war. The cylinders are made of steel inner shells surrounded by pressed-steel water jackets. The Packard Company by long experiment had developed a method of applying these steel water jackets.

The valve cages are drop forgings welded into the cylinder head. The principal departure from European practice is in the location of the holding-down flange, which is several inches above the mouth of the cylinder, and the unique method of manufacture evolved by the Ford Company. The output is now approximately 1,700 cylinder forgings per day.

Camshaft and Valve Mechanism Above Cylinder Heads. The design of the above is based on the Mercedes, but was improved for automatic lubrication without wasting oil by the Packard Motor Car Company.

Camshaft Drive. The camshaft drive was copied almost entirely from the Hall-Scott motor; in fact, several of the gears used in the first sample engines were supplied by the Hall-Scott Motor Car Company. This type of drive is used by Mercedes, Hispano-Suiza, and others.

Angle Between Cylinders. In the Liberty the included angle between the cylinders is 45 deg.; in all other existing 12-cylinder engines it is 60 deg. This feature is new with the Liberty engine, and was adopted for the purpose of bringing each row of cylinders nearer the vertical and closer together, so as to save width and head resistance. By the narrow angle greater strength is given to the crankcase and vibration is reduced.

Electric Generator and Ignition. A Delco ignition system is used. It was especially designed for the Liberty engine to save weight and to meet the special conditions due to firing 12 cylinders with an included angle of 45 deg.

Pistons. The pistons of the Liberty engine are of Hall-Scott design.

Connecting Rods. Forked or straddle-type connecting rods, first used on the French DeDion car and the Cadillac motor car in this country, are used.

Crankshaft. Crankshaft design followed the standard 12-cylinder practice, except as to oiling. Crankcase follows standard practice. The 45-deg. angle and the flange location on the cylinders made possible a very strong box section.

Lubrication. The first system of lubrication followed the German practice of using one pump to keep the crankcase empty, delivering into an outside reservoir, and another pump to force oil under pressure to the main crankshaft bearings. This lubrication system also followed the German practice in allowing the overflow in the main bearings to travel out the face of the crank cheeks to a scupper which collected this excess for crankpin lubrication. This is very economical in the use of oil and is still the German standard practice.

The present system is similar to the first practice, except that the oil, while under pressure, is not only fed to main bearings but through holes inside the crank cheeks to crankpins, instead of feeding these crankpins through scuppers. The difference between the two oiling systems consists of carrying oil for the crankpins through a hole inside the crank cheek instead of up the outside face of the crank cheek.

Propeller Hub. The Hall-Scott propeller-hub design was adapted to the power of the Liberty engine.

Water Pump. The Packard type of water pump was adapted to the Liberty.

Carburetor. A carburetor was developed by the Zenith Company for the Liberty engine.

Bore and Stroke. The bore and stroke of the Liberty engine is 5 by 7 in., the same as the Hall-Scott A-5 and A-7 engines, and as in the Hall-Scott 12-cylinder engine.

Remarks. The idea of developing Liberty engines of 4, 6, 8 and 12 cylinders with the above characteristics was first thought of about May 25, 1917. The idea was developed in conference with representatives of the British and French missions, May 28 to June 1, and was submitted in the form of sketches at a joint meeting of the Aircraft (Production) Board and the Joint Army and Navy Technical Board, June 4. The first sample was an 8-cylinder model, delivered to the Bureau of Standards, July 3, 1917. The 8-cylinder model, however, was never put into production, as advices from France indicated that demands for increased power should make the 8-cylinder model obsolete before it could be produced.

Work was then concentrated on the 12-cylinder engine, and one of the experimental engines passed the 50-hour test August 25, 1917.

After the preliminary drawings were made, engineers from the leading engine builders were brought to the Bureau of Standards, where they inspected the new designs and made suggestions, most of which were incorporated in the final design. At the same time expert production men were making suggestions that would facilitate production.

The Liberty 12-cylinder engine passed the 50-hour test, showing, as the official report of August 25, 1917, records, " that the fundamental construction is such that very satisfactory service with a long life and high order of efficiency will be given by this power plant, and that the design has passed from the experimental stage into the field of proven engines."

An engine committee was organized informally, consisting of engineers and production managers of the Packard, Ford, Cadillac, Lincoln, Marmon and Trego companies. This committee met at frequent intervals, and it is to this group of men that the final development of the Liberty engine is largely due. (*Official Bulletin*, May 16, 1918, p. 3)

New German Textile Substitute

There has been much discussion in the German press recently concerning a wood-pulp fiber named "cellulon," for which large claims are made as an efficient substitute for jute, cotton and other fibers. The Swiss spinners and weavers are keenly watching the developments of this textile substitute and already regard it as of considerable importance. A memorandum on the subject has been received by the Foreign Office from the British Consul General at Zurich, who has seen a sample of the cloth made from cellulon, and describes it as extremely strong, although made directly from wood pulp.

It is not easy to reconcile the various descriptions of the process of manufacturing cellulon from pulp, and it may be that more than one method is employed. It appears to be certain that the fiber is not made by spinning long strips of paper run off reels through water in the manner which German paper textile substitutes have made familiar. The accounts agree in describing the process, or processes, as a direct manufacture from wood pulp.

The British Consul General states that the method employed is on the same general principles as artificial-silk manufacture—that is, by squeezing pulp under high pressure through small holes in plates. He is familiar with the artificial-silk works at Crefeld and considers that the methods employed there are adaptable to making cellulon.

On the other hand, the *Münchener Neueste Nachrichten* gives some details of two processes: one, the invention of an engineer named Scherback, and the other the revival of the discovery made 25 years ago by Gustav Turk. In the Turk process, according to the Munich journal, the cellulose pulp is conducted over drums, the surface of which is divided into parallels corresponding to the number of the yarns to be produced. The roving, which consists of a solid mass of cellulose, is taken from the drum by means of a special apparatus and then twisted (i.e. finished or twined) on spinning machines.

In the Scherback process cellulose is added to cotton waste or wool in the ordinary mixed spinning process. The somewhat longer fibers of the cotton or wool bind together the shorter cellulose fibers, and thus a yarn is produced similar to cotton or woolen yarn. These processes materially differ from one another, and from the method of manufacture—similar to that of artificial silk—which is described by the Consul General at Zurich. They agree, however, in one respect: that cellulon is made from wood pulp which has not been previously converted into paper.

But however cellulon may be manufactured, there is no doubt that it is being exploited very actively in Germany, especially as a substitute for jute. The *Münchener Neueste Nachrichten*, which describes the extent of its adoption in Germany up to last month, states that many of the largest industrial concerns in the cellulose, paper and textile industries have already taken out licenses for the working of this invention. Some large factories are already at work exploiting it: other factories for such exploitation are being built or projected. The Cellulon Company has been formed by the existing license holders in conjunction with the proprietors of the patent (namely, The Turk Company, Ltd., Hamburg), with the object of establishing a research company, as well as a central point for all common interests of the cellulon industry.

The British Consul General writes that the Augsburger Spinnerei A. G. is largely interested in the Cellulon Company, and that a very powerful combination of spinners and weavers has been formed. (*Journal of Commerce*, May 31, 1918, p. 3)

Three Training Camps Open with 6,500 College Students

The following statement is authorized by the War Department:

Reports received in the Adjutant General's office indicate that the three training camps for college students opened with the full quotas present. The camps are located at Plattsburg, N. Y., where 3,000 students are enrolled; Fort Sheridan, Ill., where there are 2,500 students, and the Presidio, San Francisco, where there are 1,000. All three camps opened on Monday for a one-month course of training.

Only infantry instruction is given at these camps. Full equipment of the latest model has been furnished. The object of the camps is to prepare students with such additional training as may be prescribed for commissions in the Officers' Reserve Corps.

Those who qualified for the camps are members of Reserve Officers' Training Corps units which are located at about 120 different colleges and universities. Members of the camps receive mileage and subsistence. Most of them are under military age.

A similar camp for college students who are members of artillery units of the Reserve Officers' Training Corps at Yale University and the Virginia Military Institute, Lexington, Va., will be held at Camp Jackson, Columbia, S. C., from August 1 to September 1. These are the only schools where there are artillery units. About 350 students will be in attendance. (*The Official Bulletin*, June 13, 1918, p. 9)

The Oldest French Engineer

On May 18, 1918, Jules Gaudry, a member of the French Society of Civil Engineers, celebrated his one hundredth birthday. Notwithstanding his great age he has all his faculties and attended the meeting of the French Society of Civil Engineers at which a special medal was presented to him.

It is an interesting fact that Gaudry started his life as a law-

Jules Gaudry

yer, having even been admitted to the Paris bar, but in the 40's of the past century he entered the Cavé shops and studied steam-engine construction. In 1819 he entered the service of the state railroads, where he remained until 1870.

In 1876 he was appointed commissioner of accounts for the Trans-Atlantic Company, a position which he continued to occupy until 1906, or until he reached the age of 88 years.

In 1855 he was secretary of the Jury Commission in the general class of machinery at the famous Paris Exposition.

During the Franco-Prussian war of 1870-1871, Gaudry had the important task of acting as inspector of testing and construction of all kinds of artillery supplies, and by the time the siege of Paris by the Prussians ended he had succeeded in providing the complete material necessary for seventeen batteries.

The last paper read by Gaudry before the French Society of Civil Engineers, and bearing on the progress of engineering of water transportation, was at the age of 83 years.

British Parliamentary Commission on the Metric System

A final report has been presented to the British Parliament by the Committee on Commercial and Industrial policy after the War, which has been at work in the past two years. Chapter 10, dealing with Weights and Measures, presents the conclusions of the committee relative to the proposal for the compulsory adoption of the metric system. The 19 members were a unit in reporting adversely, and it is highly significant that this is taken to mean the dismissal of the metric-system proposal from consideration as a subject of legislation in Great Britain. Following are extracts from the report:

"Having given very full consideration to the subject, we are unable to recommend the compulsory adoption of the metric system in this country. In our opinion, it is absolutely certain that the anticipated uniformity could not be obtained for a very long period, if ever.

"There is, further, the serious objection that if we induced the above-mentioned countries to change over to the metric system, we should be surrendering to Germany the advantage which our manufacturers now enjoy over hers, both in their marks and our own.

"We are informed that even in France, which has made the metric system nominally compulsory for more than half a century, the 'pouce' (or inch) is used in textile manufacture, and numerous local measures still survive.

"In referring to these considerations, we have to point out that there is no unanimity even as to the theoretical merits of the metric system as compared with our own. The practical argument that its adoption is desirable in order to secure uniformity in the markets of the world has been shown to be unfounded. We are not satisfied by any evidence which has been brought before us that trade has actually been lost to this country owing to the fact that the use of the metric system is not compulsory.

"But to attempt to make the use of the system universal and obligatory in this country would cause loss and confusion at a particularly inopportune moment for the sake of distant and doubtful advantages. We are convinced that, so far from assisting in the reëstablishment of British trade after the war, such a measure would seriously hamper it.

"As regards the educational advantages claimed for the change, we have been referred to a statement quoted by the Select Committee of 1895 that no less than one year's school time would be saved if the metric system were taught in the place of that now in use. The information which we have received does not support that statement, and even if it were well founded, it must be remembered that for at least a generation children would have to learn both the new and the old measures and how to convert from one to the other.

"It is often popularly supposed that the introduction of the metric system would render possible the immediate sweeping away of many complicated and varying weights and measures. As we have already indicated, this belief is, in our opinion, wholly fallacious.

"We are not convinced that the metric system is, upon the whole, even theoretically superior to the British system, and we are satisfied that the practical objections to the proposed change are such as decisively to outweigh any advantages which are claimed for it." (*The Iron Age*, vol. 101, no. 21, May 23, 1918)

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Tools, Munitions, Varia

Aeronautics (See also Internal-Combustion Engineering)

STABILITY OF AEROPLANES, H. A. Webb. The writer considers the conditions of stability of an aeroplane, both in steady and disturbed flight, by the use of Newton's laws of motion and axes fixed in space. He does not discuss the practical consequences that follow from the loss of stability. It is of interest to note that the present writer does not use the usual mathematical convention, in which it is assumed that the aeroplane is travelling with a negative velocity.

The writer also gives two fundamental equations of longitudinal and lateral stability. The gyroscopic terms in the case of forward translation are claimed to be negligible, but it is stated that they may have an important effect on the stability of banked or spiral flights. (*Engineering*, vol. 105, no. 273, May 3, 1918, pp. 475-476)

EXHAUST-VALVE TROUBLES. As a result of reports of trouble on several occasions through the burning of exhaust valves or aero engines, the Rolls-Royce, Ltd., have carried out a series of experiments to determine the cause of this trouble and means for obviating it.

These tests have given some valuable results. Thus, it was found that the temperature of an exhaust valve in the hottest portion is 700 to 750 deg. cent. and the temperature of the exhaust gases in the exhaust port is approximately 700 deg. cent.

It was also found that the valve is hottest when the cylinder is working with the most efficient mixture, that is, when the maximum power is obtained with the minimum amount of fuel. Hence, the general impression that weak mixtures cause valves to get very hot was not borne out by these experiments. It was apparent that the effect the mixture had on the burning out of valves is controlled by the amount of free oxygen in the exhaust.

As regards the material used for valves, it appears that chromium steel has the advantage of not oxidizing at ordinary working temperatures. Tungsten-steel valves in ordinary conditions scale and gradually get thinner, but once the valve reaches the temperature at which burning commences the difference between the two kinds of steel is not appreciable.

The tappet clearance is of course directly affected by the elongation of the valve at normal working temperatures. Tests carried out showed that this elongation is 0.014 in. to 0.016 in. A set of valves were run with no clearance at all in the tappets when cold, so that at normal temperatures the exhaust valves did not seat by 0.015 in. The engine ran for 25 hours and the valves were in perfect condition when the test was finished. It was noticeable when the engine was running that the valves were the same heat all over, whereas in normal working conditions they all cooled on the seating where they come in contact with the cylinder. It was found that it was possible to run with the valves not seating by as much as 0.008 in. and still obtain a cooled ring round the outer ridge of the valves. It is assumed that in this case the valve is cooled by the thin volume of gas passing around the valve at a considerably reduced velocity and itself being cooled by contact with the seating of the cylinder. Investigation showed that with no tappet clearance in the exhaust valves when cold the power was reduced by 1.5 per cent, and, further, that it was possible to run with only 0.005 in. clearance with no loss of power. In carrying the tests still further, the tappets were adjusted so that the exhaust valves could never seat when cold by 0.01 in. As a result the power was reduced by as much as 15 per cent, and the exhaust valves became excessively hot. In these conditions it was distinctly noticeable that the valves were hottest on the outer ring and cooler towards the stem; thus, of course, being the converse of the results with correct tappet adjustment. This test also revealed another interesting point in that the valve was found to be much hotter on the sector towards the top center of the cylinder. This is of particular interest, because when burning occurs in an exhaust valve it has apparently never been appreciated why a bite is taken out of one portion, leaving the rest of the seating in fairly good condition. During these experiments it was noticed that this bite always occurs on the sector just mentioned towards the top center where the valve gets hottest. In conjunction with this it was also found that if a valve is turning round while the engine is running it takes a very much longer time to start to burn. Immediately burning commences the valve ceases to turn.

The effect of preignition was found to be of the greatest importance. It is stated that the spark plug which preignites under ordinary running conditions causes the exhaust valve to run at an incandescent heat. It was found that preignitions are greatly influenced by the amount of lubricating oil in the combustion chamber. In fact, it is claimed that no case of preignition has ever been known in an overlubricated cylinder and it was proved by actual experiments that if a spark plug commenced to preignite this could be redeemed by squirting a little oil into the air intake. It was also proved that it was possible to inject a certain amount of oil without affecting the horsepower of the engine and still secure a reduction of the temperature of the valve.

The Rolls-Royce Company affirms that with reasonable care

there should be no pregnition and the chief reason for its occurrence is, in their opinion, that the engine is run with the oil too cold.

It was also found in the course of tests that the water circulation has a very important effect on the overheating of exhaust valves. It was noticeable that if the water circulation is faulty the first part to be affected is the exhaust valve. If the failure of the water circulation causes the spark plug to preignite, which is natural, the valve is burned in a few minutes. They state that very encouraging results have been obtained by increasing the flow of water per minute through the cylinder jackets. (*The Auto-Motor Journal,* vol. 23, no. 19/805, May 10, 1918, pp. 338-339, *epA*)

A German "Mystery" Biplane—the H. W. Description of the so-called H. W. German biplane recently brought down on the French front.

The smash and subsequent fire did not leave much on which to base the reconstruction of the machine. Apparently, however, the biplane is a two-seater with staggered wings having a dihedral angle but no sweep back. The most characteristic element of construction is the tail, which is of the biplane form with the top plane considerably smaller than the bottom one.

The shape of the ailerons is not quite certain. One of the observers claimed that the tail planes are polygonal with the angles rounded off. It appears also that the fuselage is very deep and the top plane very close to it. This would give the rear gunner an opportunity to easily fire upwards. (*Flight,* no 487, no. 17, vol. 10, April 25, 1918, pp. 444-445)

The Story of the Liberty Motor. This article claims to give the true story of the Liberty motor. There are no facts which were not previously known in one way or another, but the whole article gives a very clear and consistent history of this interesting war development. Engineering Materials

Failure of Ductile Materials Unler Fluctuating Stresses, H. A. Webb and W. H. Barling. The paper starts with a brief introduction and a summary of previous work on fatigue of materials under fluctuating stresses. The writer believes that

$$\text{Equivalent static stress} = \frac{2\ (\text{maximum stress})}{1 + \frac{1}{2}\frac{(\text{minimum stress})}{(\text{maximum stress})}}$$

is well supported by experiment for ductile materials under fluctuating direct stresses, and by analogy with it suggests the following formula for ductile materials under more complicated conditions of loading.

Let s_1 and s_2 be the maximum and minimum shear stresses (s_2 may be negative) at a given point, in a given plane through that point; then the equivalent static shear stress at that point, and in that plane, is

$$s = \frac{2s_1}{1 + \frac{s_2}{2s_1}}$$

Taking as an example the crankshaft of an aero engine, the shaft is subjected, at any given section, to a fluctuating direct stress, p, due to bending and thrust, and a fluctuating shear stress, q, due to torque. Let p and q be represented on a polar diagram, as in Fig. 1.

Let p_1, q_1, and p_2, q_2, be two pairs of corresponding values of p and q, i. e., p_1 and q_1 occur simultaneously, and so do p_2 and q_2. We assume temporarily that p_1 and q_1 represent the limits of fluctuation, and on this assumption we shall find a formula for S. In theory, we ought then to apply the formula to read off from the polar diagram and choose the largest of all the values of S so obtained, as the "maximum maximorum." In practice, experience should enable us to guess from the diagram, as a rule, what values of p_1 and q_1, p_2 and q_2 are likely to give the largest value of S. Probably

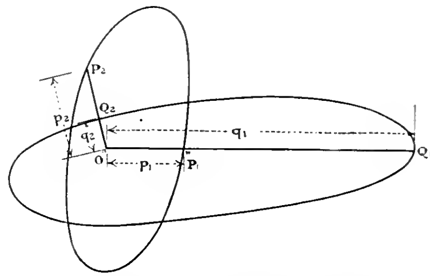

Fig. 1 Polar Diagram of Stresses on a Crankshaft of an Aeronautical Engine

we should not be far wrong, for a crankshaft, in taking the greatest and least values of q (the least value may be negative), together with the corresponding values of p, to determine the value of S.

We shall then prove that if

$$H = \frac{p_1q_2 - p_2q_1}{q_1^2 + \frac{1}{2}q_1q_2 + \frac{1}{4}p_1^2 + \frac{1}{8}p_1p_2} \quad \text{[4a]}$$

is numerically greater than 1.414, then

$$S = \frac{2(p_1q_2 - p_2q_1)}{\sqrt{(q_1+q_2)^2 + \frac{1}{4}(p_1+p_2)^2}} \quad \text{[5]}$$

But if

$$H = \frac{p_1q_2 - p_2q_1}{q_1^2 + \frac{1}{2}q_1q_2 + \frac{1}{4}p_1^2 + \frac{1}{8}p_1p_2} \quad \text{[4b]}$$

is numerically less than 1.414, then S either has the value given in [5], or it is equal to

$$\frac{2(q_1^2 + \frac{1}{2}q_1q_2 + \frac{1}{4}p_1^2 + \frac{1}{8}p_1p_2)^2 + (0.3)(p_1q_1 - p_2q_1)^2}{\{(q_1 + \frac{1}{2}q_2)^2 + \frac{1}{4}(p_1 + \frac{1}{2}p_2)^2\}^{3/2}} \quad \text{[6]}$$

whichever is the greater numerically.

TABLE 1 DUCTILE MATERIALS UNDER FLUCTUATING STRESSES

p_1	q_1	p_2	q_2	S
23,000	4,600	12,300	0	20,200
3,600	12,000	0	4,800	20,300
12,500	10,000	7,500	5,000	19,500
12,000	5,000	6,000	−5,000	20,000
2,000	5,000	1,000	−5,000	20,400
2,500	7,500	0	−3,700	20,100
9,000	7,500	3,000	−3,000	20,100
12,000	6,000	−9,000	4,500	20,400

These formulæ are proven mathematically. This part of the paper is not suitable for abstracting.

The writer gives the following numerical illustrations: As a special case if $q_1 = q_2 = 0$, we find from [6] that

$$s = \frac{p_1}{1 + \frac{p_2}{2p_1}}$$

which agrees with [2] (as we should expect), since under a simple tension the maximum shear stress is half the tensile stress.

In the eight cases given in Table 1 the value of the equivalent static shear stress is about 20,000 lb. per sq. in., so that they are all, on this theory, about equally wrong. All the stresses are in pounds per square inch. (*Aeronautics*, vol. 14, no. 235, April 17, 1918, pp. 331-333, 3 figs., *tm*)

PRINCIPAL PROPERTIES OF ACIERAL. A new aluminum alloy under the name of acieral was placed on the market last year (for details of its composition see *The Iron Age*, April 5, 1917). Some tests of this metal have recently been made by the Bureau of Construction and Repair of the United States Navy, with results shown in Table 2.

These tests represent metal varying from 0.064 in. and up in thickness. (*The Iron Age*, vol. 101, no. 23, June 6, 1918, p. 1467, *e*)

TABLE 2 RESULTS OF TENSILE TESTS OF ACIERAL

Grade of alloy	Original area, sq. in.	Proportional limit, lb. per sq. in.	Ultimate strength, lb. per sq. in.	Elongation in 2 in., per cent	Reduction of area, per cent	Modulus of elasticity, lb. per sq. in.

ANNEALING AND RECRYSTALLIZATION OF COLD-ROLLED ALUMINUM SHEETS, Robert J. Anderson. The present article gives the results of a series of tests made on the effects of heat at different temperatures on the softening of cold-rolled sheet aluminum.

The main results of these tests have been reported in an abstract of another article by the same author in THE JOURNAL for June 1918, p. 506.

The present investigation, on the whole, shows that the existing general practice of annealing aluminum is faulty. The effect of long-time annealings, such as are common in present practice where sheets are exposed for, say, 24 hours at 375 deg. cent., is to cause an undue coarsening and weakening of the metal, evidenced by the coarse domes in the Erichsen test used in the present investigation.

Fabricating blanks which have been so annealed and which have undergone deep draws in the draw press also show the same coarse appearance at the edges of drawn shapes and this can be traced only to the long annealing period. (*Metallurgical and Chemical Engineering*, vol. 18, no. 10, May 15, 1918, pp. 523-527, 6 figs., *ep*)

THE ANNEALING OF CARBON STEELS AS AFFECTED BY VARIOUS TEMPERATURES AND MAGNETIC FLUX, R. B. Fehr, Mem.Am.Soc.M.E. The primary object of the investigation was to make a study of the range of temperature in which the various steel heat-treating operations should be carried out. For this purpose the critical range of temperatures was investigated through *small* intervals with the object of finding out what improvements would be brought about by better temperature control.

This research made it also possible to investigate whether there was any unusual effect on the physical properties of steel that was subjected to heat treatment and the action of magnetic flux simultaneously.

The main data of this investigation have already been reported from an advance publication of the paper in THE JOURNAL for January 1917, pp. 82-84. (*Pennsylvania State College Bulletin*, vol. 11, no. 11, October 1, 1917, *e*)

OCCLUDED GASES IN FERROUS ALLOYS, Gellert Alleman and Charles J. Darlington. Interest in occluded gases was aroused in the writers during an investigation conducted by one of them which had to deal with the bubbles formed around wire in wire glass. At first, it was assumed that these bubbles were composed of carbon dioxide and emanated from the glass itself, but subsequent work indicated the possibility of the gases coming from the metal of the wire.

A series of extensive tests was undertaken which gave some interesting data, summed up by the writers in the following manner:

1 We have constructed a gas-tight vacuum furnace, capable of continuous service at temperatures of approximately 1900 deg. cent.

2 By means of this apparatus, all the gases occluded in ferrous alloys may be removed and collected.

3 It appears that the gases are evolved in the following order: hydrogen is most readily set free, carbon monoxide comes next, and nitrogen seems to be held most tenaciously.

4 Whether oxygen is the result of the decomposition of various oxides of iron or the dissociation of carbon monoxide or carbon dioxide has not been determined.

5 We have shown that ferrous alloys may occlude relatively large volumes of gases—in some cases equal to about 200 times the volume of the metal.

6 We suggest that in addition to the ordinary functions of metals like aluminum, tungsten, chromium, menganese, titanium, silicon, etc., when placed in ferrous alloys these elements may act as catalytic agents and either prevent the occlusion of large quantities of gases or aid in the elimination of such gases at lower temperatures than would ordinarily take place.

7 We have shown that the removal of gases from ferrous alloys markedly changes the microstructure and increases the density of the alloy. (*Journal of The Franklin Institute*, vol. 185, no. 4, April 1918, pp. 461-480, 4 figs)

THE INFLUENCE OF SURFACE TENSION, F. C. Thompson. *The Iron Trade Review*, vol. 62, no. 12, May 23, 1918, pp. 1299-1304, 9 figs. Reprint of a paper presented at a recent meeting of the British Iron and Steel Institute. The hypothesis is offered for surface tension and bears an important influence on the structure of iron and steel.

THE DEFINITION OF HARDNESS, W. Cawthorne Unwin. The writer points out the interesting fact of the identity of the hardness numbers of Martel and Brinell. In view of the fact that Martel's work is comparatively little known, the following passage from the article is of particular interest:

In 1895 to 1900 Lieutenant-Colonel Martel communicated two very interesting and valuable papers to the Paris Congress on testing materials. He used the falling-monkey

method with various forms of indenting points and various heights of fall. He established conclusively that the work expended in indentation, notwithstanding these variations of the conditions, is proportional to the volume of the indentation.

If V is the volume of the indentation, P the weight of the monkey and F the height of fall, $D = PF/V$ is constant for any given ductile material. Then D in kilogram-millimeter units is Martel's hardness number.

It is easy to see that D is the amount of work necessary to cause a cubic unit of indentation and is independent so far as the tests go of the form of the indenting body.

Further, a few tests were made with a gradually applied load and the same law was satisfied, except that D was about

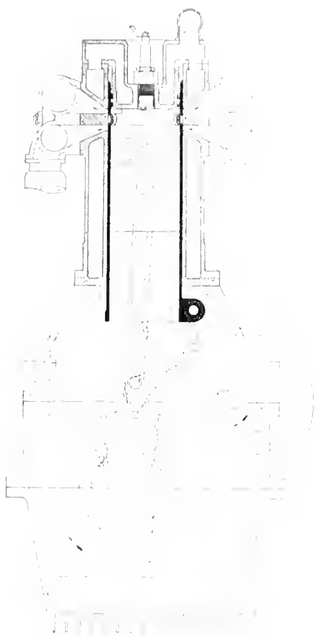

FIG. 2 SINGLE-SLEEVE-VALVE MOTOR

20 per cent less in the case of a gradually applied load. Probably this was due either to there being some loss of work in vibrations, etc., in the impact test; or to inexactness in determining the work expended in tests by a gradually applied load. ALCOHOL AS A MOTOR FUEL. Report by the Commonwealth Advisory Committee on Science and Industry presented to the Australian government on alcohol fuels and engines. The report considers in very favorable light the possibility of using alcohol as a fuel. For denaturants it recommends tar-oil distillates as being cheap, effective and having no corrosive effect on valves or cylinders. For Australian conditions the use of mixtures of alcohol with benzol or ether are not recommended. As regards the source of raw materials the report recommends the use of molasses, sorghum stalks, cassava and sorghum grain. SINGLE-SLEEVE-VALVE MOTOR. A new sleeve-valve engine is being developed by the S. S. V. Motor Company, of Pittsburgh, Pa., the design being due to Charles B. and James M. Gearing. A cross-sectional view of the engine is shown in Fig. 2.

The engine has four cylinders of $3\frac{1}{2}$ in. bore by 5 in. stroke, and a single sleeve is interposed between each piston and its cylinder wall. The sleeve, of course, reciprocates at one-half the speed of the piston, making one reciprocation during each complete engine cycle. Its travel is equal to 13-16 in. This makes a total travel of $1\frac{5}{8}$ in. during a complete cycle, as compared with 20 in. of piston travel. The sleeve is said to have a dwell corresponding to 275 deg., during which period the compression and power strokes take place. The ports in the cylinder wall and in the inner head are so arranged that the port in the sleeve is between the inlet and exhaust ports during this particular period.

When the crankshaft is 45 deg. from the bottom dead center on the power stroke, the sleeve moves up and begins to open the exhaust port. The latter closes at the top dead center. The inlet port is opened by a quick motion of the sleeve valve.

There are two inlet and two exhaust ports to each cylinder. The sleeve is positively operated by a double toggle combination, one link of which is driven by an eccentric shaft rotating at one-half crankshaft speed and the other half by an eccentric which is placed above the crankshaft and operated by means of the connecting rod so that it has an irregular angular motion. The upper end of the two links is connected by a third link to a lug on the sleeve.

The whole cylinder block is an aluminum casting, without special lining, as all of the wear comes on the inside of the sleeve. An experimental engine that has been built developed

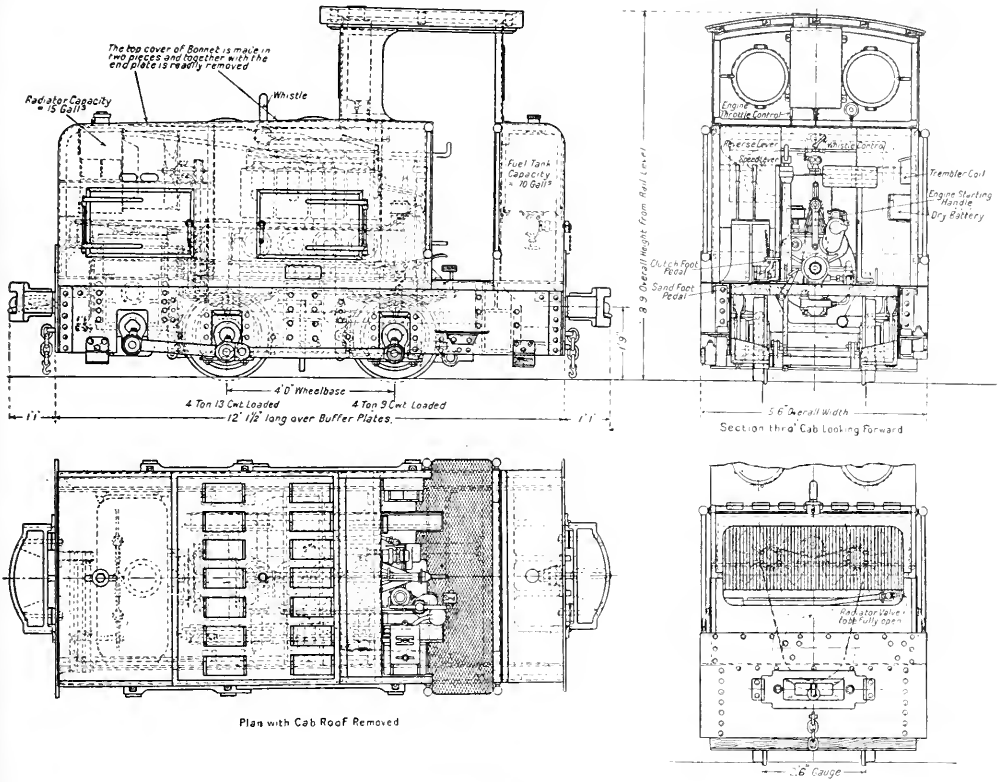

Fig. 3 British Narrow-Gage Internal-Combustion Locomotive

a torque of 110 lb. (length of brake arm not given) at 1400 r.p.m. The spark plugs are located centrally in the cylinder heads. This engine will run up to 2700 r.p.m., it has been definitely stated.

The exhaust ports have their top edge on a line with the bottom of the inner head and are 2 7-18 in. wide, measured circumferentially. They afford a very direct passage for the exhaust gases from the cylinder and this is believed to have a tendency to keep the cylinders free from carbon.

Lubrication is by the force-feed system, oil being fed under a pressure of 5 to 10 lb. per sq. in. to the three main bearings and through drill holes in the crankshaft to the crankpin bearings. Oil thrown off from the crankpin bearings lubricates all the other internal parts. The sleeve-operating shaft, as will be seen, is chain-driven. (*Automotive Industries*, vol. 38, no. 20, May 16, 1918, p. 953, *d*)

Small Locomotives of Special Types. The first of a series of articles describing small locomotives such as are used by contractors or for special purposes. The locomotives described are both steam and internal-combustion, the steam locomotives being of the fireless type.

As regards fireless locomotives, the one described is built by Hawthorn, Leslie and Company. A particular feature of the engine is a special superheater and steam drier which is claimed to effect a gain in efficiency ranging from 10 to 15 per cent, according to the charging pressure available and the pressure at which the reducing valve is set. It is said that it has been found that in order to obtain a perfectly satisfactory operation of reducing valves, it is necessary to provide an adequate volume of steam between the valve and the cylinders so as to act as a cushion on the reducing valve and prevent violent fluctuations in the pressure of steam in the delivery pipe. The superheater referred to here does it, and, in addition, also provides a reservoir of low-pressure steam, which is drawn upon for supplying the cylinders and, at the same time, allows the steam to become thoroughly dried before entering the cylinders for a period when the reservoir is at or about at its maximum pressure and corresponding temperature. The amount of superheat gradually decreases until the point is reached when the pressure in the reservoir corresponds with that at which the reducing valve is set. During the ensuing period of working, the reducing valve ceases to be operated and passes the steam directly from the reservoir to the cylinders at a gradually falling pressure.

The same firm builds an internal-combustion locomotive driven by a 4-cylinder marine-type engine designed to develop 55 b.hp. at 600 r.p.m. The power is transmitted through a friction clutch to a change-speed gearbox, arranged to give traveling speeds of 4, 8 and 15 miles per hour, both forward and backward.

The unit has a weight in full running order of 8.75 tons and runs on a gage of 2 ft. 6 in.

Another type described in the article is the narrow-gage internal-combustion locomotive built by the Avonside Engine

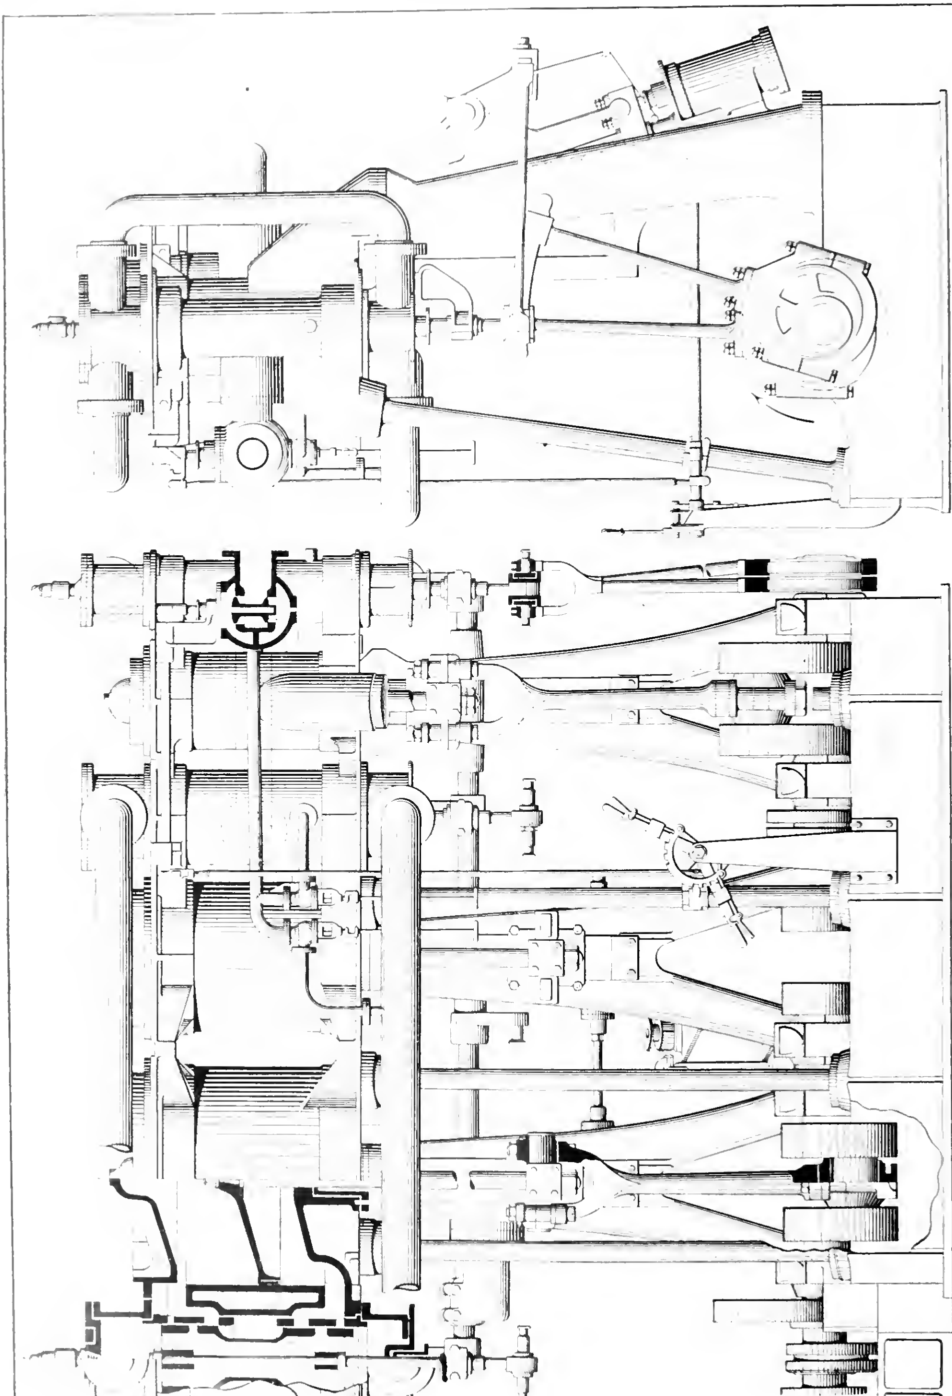

FIG. 4 GENERAL ARRANGEMENT OF THE EMERGENCY FLEET FORE-AND-AFT TRIPLE-EXPANSION ENGINES

Company at Bristol (Fig. 3). This locomotive is of the M. L. M. type; that is to say, it is from 55 to 60 hp., and is suitable for gages varying from 1 ft. $11\frac{5}{8}$ in. to 5 ft. 6 in., the drawing here showing a 2 ft. 6 in.-gage locomotive.

There are four wheels 2 ft. in diameter and coupled, the wheelbase being 4 ft. The total weight loaded is 9 tons and 2 cwt., 4 tons 13 cwt. being on the front axle and 4 tons 9 cwt. on the rear axle.

The motor is of the four-cylinder ($6\frac{1}{2}$ in. by 8 in.) vertical type, designed to run normally at 550 r.p.m. The power is transmitted through a clutch and change-speed gearbox, no chains being used. The engine is designed to work on any ordinary kerosene having a flash point up to about 150 deg. fahr. It is started from cold by running on gasoline for a few minutes and changing over to kerosene. (*The Engineer*, vol. 125, no. 3255, May 17, 1918, pp. 419-421, 5 figs., *d*)

Machine Tools

Bullard Maxi-Mill Boring Mill. Description of a boring mill embodying in its construction some features which are stated to have never before been applied to a machine of this type.

In the new mill such standards and complete units as the drive, feed works, spindle construction, rail construction have been embodied with only minor changes, but new features also appear.

In the bed the gears and bearings are flooded with oil at all times.

A new form of centralized control has been introduced. The crank handles were eliminated on the hand wheels, these being of the hammer type, which is claimed to make possible very fine settings of the tools.

Graduated scales mounted on the face of the cross rail and on the tool slides give the coarser readings, while micrometer dials graduated to thousandths and equipped with Bullard observation stops give the final readings.

Another feature of construction claimed to be new permits the use of large and effective amounts of cutting lubricant on the tool. In fact, the machine was designed with this in mind from the start and it is claimed that the construction is such as to avoid the possibility of the cutting lubricant entering parts of the machine where it is not desired. (*American Machinist*, vol. 48, no. 23, June 6, 1918, pp. 973-974, 4 figs., *s*)

Emergency Fleet Engines. In view of the great interest naturally felt by American engineers in propelling machinery of the Emergency Fleet ships, there is reproduced on the opposite page from *Power* a cut showing the general arrangement of the fore-and-aft triple-expansion engine built for the Corporation by the Buckeye Engine Company.

It is of 700-hp. capacity and has a $15\frac{1}{2}$-in. diameter high-pressure cylinder, a 26-in. intermediate and a 44-in. low-pressure cylinder with a stroke of 26 in. Piston valves are to be used on all cylinders and are $7\frac{1}{16}$, $14\frac{1}{16}$ and 15 in. in diameter, respectively, and 3 ft. [illegible] in. long.

The columns on which the cylinders are secured are 7 ft. 1

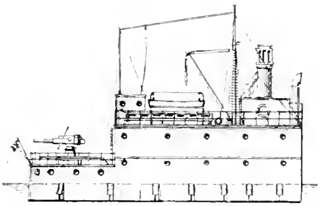

Fig. 5 Diagram of a Large Poop-Type Detachable Ship Electromobile When Not Attached to the Ship

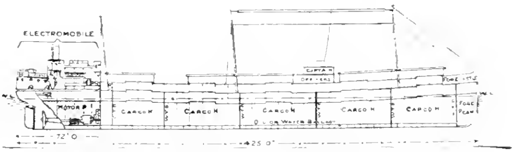

Fig. 6 Cargo Ship of 10,000 Tons Deadweight Carrying Capacity on the Snell Electromobile System

in. high and 7 ft. wide at the base. The frame consists of a front and back column. The front column is $4\frac{1}{2}$ in. in diameter and the back column is of A-shaped form when looked at from the forward end. These columns carry the guide bars.

The crankpins are $8\frac{1}{2}$ in. and the wristpins $4\frac{1}{2}$ in. in diameter. The shaft is $8\frac{3}{8}$ in. in diameter and the cranks are placed at 120 deg. apart. (*Power*, vol. 47, no. 23, June 4, 1918, pp. 794-795, 2 figs., *dA*)

Snell System of Electric Propulsion for Ships. The Snell system of electric propulsion is to be used in particular for ships operating under such conditions that the time of loading and unloading is considerably greater than the time during which the ship is under way. This applies in particular to cross-channel navigation.

Instead of a complete set of machinery in each ship, the Snell system provides one set of transferable power-producing machinery so constructed as to be attachable to several independent hulls. Only propellers and electric motors, which form a small proportion of the total cost of machinery, are fixed in the hulls themselves and are connected during the voyage to the power-producing machinery by electric cables.

The hulls of the ships may be similar to those of ordinary cargo steamers, the space usually occupied by engine and boiler being available for cargo. The power-producing plant will consist preferably of internal-combustion engines or high-speed steam turbines driving alternators, the whole enclosed in a detachable structure of special design carried on the stern or amidship of the hull and firmly attached thereto during the voyage.

Such a detachable "electromobile" with Diesel engines of 4500 b.hp. is shown in Fig. 5, while a cargo ship with the electromobile attached is shown in Fig. 6.

It is claimed that this system insures greater safety against torpedo attacks, as the hull is practically independent of the machinery. Even if it be seriously damaged, the ship, with its machinery intact, would have a good chance of making port. Further, as the electromobile is to be constructed so as to have flotation of its own when not engaged in propelling ships, the machinery portion may be saved even should the hull be so damaged as to cause it to sink.

It does not appear whether any ships on the Snell system have been actually built, the whole matter being quite new. (*Snell Economic Ship*, January 1918, 14 pp. and 2 plates, *d.*)

Measurements

VARIANCE OF MEASURING INSTRUMENTS AND ITS RELATION TO ACCURACY AND SENSITIVITY, Frederick J. Schlink, Mem.Am. Soc.M.E. Instrumental variance, which forms the major part of the discussion of this paper, is a factor whose effect in causing error in measuring instruments has hitherto been given but little consideration. In order to bring out the essential relations of the variance characteristic, the paper opens with a discussion of accuracy and sensitivity, showing how each of these terms can be given precise definition with definite numerical significance. Such values when determined have important use in establishing the figure of merit or value of a given instrument or type of instrument. A distinction is drawn between the commercial accuracy commonly called for in direct-reading instruments of the shop and plant, and the higher grade of accuracy required in the laboratory where instrumental indications are normally subject to the application of corrections for error of calibration.

A definition of sensitivity of an instrument is of real significance only when there are means for expressing it numerically. It is suggested that the unit of response for an instrument should be based upon a definite and inherent characteristic of that instrument rather than upon some accidental factor, such as the length of a pointer or an arbitrarily graduated scale.

The paper shows the necessity for distinguishing between insensitiveness and passiveness or sluggishness in an instrument, and consideration is given to the effect of friction in preventing response to certain small changes in the measured quantity. The paper gives the following definition of sensitivity:

Sensitivity in an instrument is the rate of change in the indicating of such instrument with respect to the change in the quantity being measured, it being necessarily assumed for the purpose of this definition that friction and lost motion in the mechanism have been eliminated or are negligible.

The amount of the least alteration in the value of the measured quantity, producing instrumental response, divided by the initial value of the measured quantity may be called the passivity of the instrument at that point. Passiveness is a special case of the phenomenon of variance, next discussed.

Variance is defined as the range, at any given value of the measured quantity, of variation in reading which may be exhibited by the instrument under repeated application of the same value of the quantity being measured, after a steady reading has been attained—the environment remaining unchanged.

The specific variance or variancy may be defined as the ratio of the range, at any given value of the measured quantity, of variation in reading which may be exhibited by the instrument under repeated application of the same value of the quantity being measured, divided by the measured quantity itself, the same assumptions applying as above as to the attainment of a steady state of indication and as to the maintenance of unchanged environment.

Determination of the variance is a most important part of the calibration of an instrument and appreciable error may arise from failure to recognize or express it.

The paper illustrates the derivation of the variance from a certain hysteresis loop and discusses in detail the phenomena occurring in the measuring instruments used therefor. It also analyzes in detail the possible sources of inaccuracy and shows, among other things, that the phenomena usually ascribed to the operation of friction of resistances only may be due to more complicated causes.

The frequency-curve method of delineation is applied to the expression of variance of an irregular nature, as found in instruments exhibiting bad workmanship or ill repair, and it is seen that the variance characteristic of such an instrument can be completely defined by reference to a family of frequency curves obtained in the following manner: One series of points will be plotted for readings taken at varying rates and amounts of increase of the measured quantity terminating in the value corresponding to the particular point of the scale under investigation, and another set for decreasing values terminating at the same point. Such a curve, in which frequency of occurrence of a particular reading or error is plotted against the true value of the measured quantity at that reading, gives the probability of occurrence of any amount of variation from, say, the mean instrumental reading.

Far from being a relatively unimportant source of inaccuracy in measuring instruments, it can be shown that the hysteresis or variance type of error demands consideration in practically every type of instrument, while in some (such as pointer-and-dial types of displacement indicators) it is a preponderating factor in design and actually limits the application or utility of the instrument and sets the limit of sensitivity and accuracy practicably to be obtained.

A few means of reducing instrumental variance are given, including the use of special types of bearings in which slack or clearance can be reduced to a minimum without impairing easy operation; and the use of flexible elastic connectors between elements of the linkwork instead of gears and racks or pin-and-link connectors. Such tape-like connectors which may wind on cam-shaped members to provide for correction of displacements to a linearly graduated scale, exhibit excellent properties in the matter of reversibility of calibration, and have important advantages over the more usual types of linkwork details.

The action of vibration in reducing instrumental variance is found in accord well with the principles previously set down, and it appears that, within limits, errors of result due to mechanical sources of variance can be considerably reduced by judiciously applied vibration treatment.

In designing and constructing an instrument, due consideration should be given to the effect of variance errors in

practically limiting the sensitivity to be sought in adjustment, as well as the interval between the graduations and the smallness of the units of graduation. It is suggested that in view of this condition, the mean interval of graduation of laboratory instruments should not be less than five times the mean variance, while for commercial or plant instruments the ratio of mean scale interval to mean variance may be of the order of two to one. Likewise the sensitivity may easily be disadvantageously high, inducing erroneous estimates of the precision of results and requiring special care in the calibration and use of the instrument.

The factors of maximum or mean inaccuracy (or accuracy), sensitivity, variancy and special set (the amount of which the variance loop may fail of closure, divided by the range of the deflection cycle) may be referred to the total range of graduation instead of to particular values of the measured quantity under observation, as a convenient means of arriving at single significant numbers to be composed into a "figure of merit" for an instrument whose characteristics are being determined. (Abstract of Scientific Paper now in press, U. S. Bureau of Standards.)

Milling-Machine Dynamometer. Description of a dynamometer specially designed for use on the milling machine, by R. Poliakoff, Mem.Am.Soc.M.E. The general design of the instrument is shown in the accompanying illustration, Fig. 7. It is adapted to measure the pressure exerted in milling cuts resolved into three components, each one at right angles to the other two. In this respect it goes much further than the usual machine-tool dynamometer.

Its operation is substantially as follows: The instrument is mounted on a foundation plate *A*, which rests upon the table of the milling machine and is attached thereto by bolts in the usual manner. The work to be milled is placed on the auxiliary table *B* and made fast thereto. The work and milling cutter are then brought together and the cut started.

The resulting pressures exerted on the work upon the table *B* may be resolved into three components.

Referring to Fig. 7, the horizontal arrow pointing in the right-hand direction indicates the direction of one of these components. The vertical arrow pointing downward toward the table indicates a second component. The direction of the third is parallel with the surface of the table at right angles to the other two. So the resultant pressure can be split up into three components and each is registered on a separate gage of the instrument. Two of these gages are shown in Fig. 7. The pressure is transmitted by causing a flow of liquid to register accurately upon the gages the amount of the pressure in each of the three directions.

The instrument is adapted to determine the pressure required for various milling operations, and thereby assist in determining the strength of the parts of milling machines or to analyze the action of various types of cutters or the degree of difficulty for cutting the various materials. Mechanics

Leaf Springs, Their Capacity for Dissipation of Energy, C. P. Schwarz. The writer discusses the potential dissipation of a spring, or its ability to dissipate energy when subject to shock. He gives expressions for this energy which depend entirely upon the structure of the spring and which would express the amount of heat dissipated by the spring as soon as the value of a certain coefficient is experimentally determined.

The analysis of the expressions derived by the writer discloses some interesting facts. The dissipation increases in the same ratio as the product of the thickness of the leaves and their number, not counting the master leaf. That is really the height of the spring. Locomotives which require springs with high dissipation have springs composed of numerous leaves of very substantial thickness.

The dissipation decreases with the length of the master leaf; if, however, all leaves are made of the same length ($= 2\ L$) the dissipation is doubled.

When a maximum of dissipation has to be accompanied by a minimum of weight the semi-elliptic spring is unexcelled. The three-quarter elliptic, platform, and full elliptic spring follow in the order enumerated. The cantilever spring is theoretically equal to semi-elliptic. However, it must be provided with a "dead" end for anchoring purposes, and then its weight efficiency is reduced.

To increase the dissipation until a practically satisfactory

periodicity is reached two main avenues of development are open to us, leading to:

1 Thin leaf spring

2 Spring with inserts.

$$W = 2/3Fn(R^2\text{sine}\,\alpha - R^2\text{sine}\,\alpha\cos\alpha)$$
$$= 2/3FR^2n(\text{sine}\,\alpha - \tfrac{1}{2}\text{sine}\,2\alpha)$$
$$\frac{W}{2/3FR^2n} = \text{sine}\,\alpha - \tfrac{1}{2}\,\text{sine}\,2\alpha \qquad (2)$$

FIG. 8 RESISTANCE TO ROLLING OF A HARD CYLINDRICAL BODY

$$\text{Mean unit pressure} = \frac{W}{FR\text{sine}\alpha}$$
$$= 2/3 \text{ maximum unit pressure.}$$
$$\therefore \text{Max. unit pressure} = 3/2\ \frac{W}{FR\text{sine}\alpha}$$

Which varies as depth from zero at the surface.

$\therefore$ Work per unit area $=$

$$d \times \tfrac{1}{2} \times 3/2\ \frac{W}{FR\text{sine}\alpha}$$

Work of depression over distance 1 with resistance P is $\frac{3}{4}\ \frac{W}{FR\text{sine}\alpha}\ dF1 = P1$

$$\therefore \frac{P}{W} = \tfrac{3}{4}\ \frac{d}{FR\text{sine}\alpha} = \tfrac{3}{4} \text{ slope of chord}$$
$$= \tfrac{3}{4}\tan\tfrac{1}{2}\alpha$$
$$\text{or } G = \frac{P}{W} = \tfrac{3}{4}\tan\tfrac{1}{2}\alpha \qquad (3)$$

FIG. 9 EQUATION FOR THE EFFECT OF DEPRESSION OF SOIL THROUGH A BODY ROLLING UPON IT

It can be shown that

$$\text{Cos}\alpha = \sqrt{\frac{2P}{FR^2n}} - 1$$
$$d = R - R\cos\alpha$$
$$d = \sqrt{\frac{2P}{Fn}} \qquad (5)$$
$$P = \tfrac{1}{2}d^2Fn \qquad (6)$$

Or resistance depends upon depth of depression, face of tire and soil factor, irrespective of diameter and weight.

Knowing the soil flow and bearing value, P could be determined from the track alone.

FIG. 10 FACTORS DETERMINING THE MAGNITUDE OF RESISTANCE TO ROLLING

RESISTANCE TO ROLLING OF TRACTOR WHEELS IN SOFT GROUND, Amos F. Moyer, Mem. Am.Soc.M.E. Preliminary report of a research conducted with financial assistance from the University of Minnesota Research Fund and from the Society of Automotive Engineers to determine the relation between rolling resistance, specific load, wheel diameter, speed, and other factors.

The mathematical derivations which it was proposed to verify by these experiments were based on the assumption that soft soil and probably other plastic materials bore up a unit pressure proportionate to the depth of depression. This is equivalent to saying that the total weight borne up is proportionate to the volume perpendicularly enclosed by the displacing surface in actual contact with the substance and below the surface from which the substance was displaced.

In the case of a hard cylindrical body rolling on a level plastic surface this volume consists of prismatic half-segments of the cylinder below the level surface and on the forward side, but, if the deforming body, instead of being a cylinder, were rounded upward in front and continued flat for some distance backward, as in the case of a sled runner or caterpillar tread, the supporting volume of displacement would include also the rectangular prism extending backward a distance equal to the flat supporting surface, which explains the greater carrying capacity of surfaces of this kind. The experiments thus far conducted were confined to plain, flat-tired wheels of varying weight, width and diameter.

In Fig. 8, Equation 1 expresses approximately the low outline for a cylindrical body for plain, flat-tired wheels, where n is the load supported by the soil per unit volume displaced. From this is deduced Equation 2, which expresses a similar law in terms of the wheel dimensions and the arc α which is in contact with the soil.

Fig. 9 gives equations derived through the application of the principle of conservation of energy, by virtue of which it must be true that the work done in rolling a wheel a given distance is equal to that expended in depressing the soil over the same distance.

In Fig. 10, P represents resistance, or pull required to roll the wheel, and this divided by the weight of the wheel is G, or Equivalent Grade, which is the percentage grade, such that if the wheel rolled upward without friction on a hard surface it would give the same resistance as P.

The value given here, or $\frac{3}{4}$ tan $\frac{1}{2}$ α, or three-quarters of the slope of the chord subtending the arc of contact, is a much smaller quantity than some of the data previously published on loss in rolling a round wheel would lead one to believe.

Referring again to Equation 2 in Fig. 8, it is evident that the factors in the denominator other than n are proportional to the cylindrical volume of the wheel, which may be called Q. In the calculations this has been expressed in cubic feet, so that W/Q, which is designated as S, or specific load, is written in pounds weight per cubic foot of wheel volume, and the writer proves mathematically that there is a fixed relation between S and G whenever n remains constant. He also shows that resistance depends upon the depth of depression, face of tire and soil factor, but is independent of diameter and weight. Hence, knowing the soil flow and bearing value, P can be determined from the track alone. In other words, if we know anything about the soil, that is, if we know n, we can tell the resistance of a wheel even if we never have seen anything but the track.

The writer proceeds then to describe the apparatus used in the tests and the method of carrying them out, which indicates the considerable amount of work spent in the present investigation.

This attaches considerable interest to the question whether the values of n found in the present investigation actually

represent weight borne per cubic inch of soil displaced, or merely a hypothetical something which will satisfy a complicated equation. On obtaining data on the actual displacement of soil there was no means at hand for ascertaining the "wave" action in front of the advancing wheel, and merely the volumes were calculated which were below the original soil surface. This "wave" action and the small bank of loose earth which always forms in immediate contact with the tire reduce the value of n, but this happens to be obtained also by the mathematical determination of n from S and G, which would indicate that the mathematical determination of n automatically takes into account several variables which apparently would be difficult to determine by measurement. When the laws of variation of n are once determined, the values thus established will give true values of resistance, since resistance is the quantity whence they are derived. (*Automotive Industries*, vol. 38, no. 20, May 16, 1918, pp. 949-953, *e*)

New Theory of Plate Springs, David Landau and Percy H. Parr. The paper starts with a survey of the previous work on the theory of plate springs and from this proceeds to the consideration of such theory, and description of experiments carried out by the writers.

The new theory is based on the consideration that any leaf of a spring, except a short plate, has a beam *encastré* at one end, loaded at the other, and having a flexible support somewhere between the point of encastrement and that of application of the load.

The writers derive an equation expressing the fundamental relation between the lengths of the leaves and their corresponding reactions of tip pressures. Among other things, this equation shows that the strength of a spring is not nearly in direct proportion to the number of plates, and also explains why the endurance at a given deflection decreases with the increase in the number of leaves.

The writers claim that the fundamental reason for the failure of the old theory is that it ignores the clamping of the leaves at the center of a semi-elliptical spring or at the end of a cantilever spring, this effect of the clamping being sufficient to vitiate the old theory to such an extent as to render it useless from both the theoretical and practical points of view.

The question of the permissible load that any spring may safely carry according to the new theory is discussed in detail. The writers claim that a two-leaf spring has 1.6 times the strength of a single-leaf spring.

The following two general laws are formulated with regard to non-tapered leaf springs:

1 In any leaf spring having leaves of equal cross-sections, and with equal steps, the reactions or pressures between the leaves continually decrease from the short leaf toward the master leaf, as do likewise the stresses.

2 In any leaf spring having leaves of equal cross-sections, and in which the reactions or pressures between the leaves are equal, the steps or overhangs continually decrease from the short leaf toward the master leaf. Grain-Dust Explosions, B. W. Dedrick and David J. Price. Investigation of conditions under which carbonaceous dusts became explosive carried out in the experimental attrition mill at the Pennsylvania State College.

Under the term "carbonaceous dusts," in this investigation, in addition to coal dust, are comprised other types of dusts now known to be inflammable and capable of propagating flame, such as dust in flour and feed mills, grain elevators, threshing separators, etc.

The investigation conducted was undertaken for the determination of possible causes of explosions and the testing of various preventive measures suggested. It was carried out along very broad lines, but only the features of interest to mechanical engineers are briefly abstracted here.

In the original article the results are presented in the form of tables and the experimental installation used and methods employed are described in detail.

As regards the explosibility of various grains, it was found that elevator dust flour, wheat scourings and malt sprouts seem to produce explosions the most consistently, while oat hulls do not appear to give very inflammable mixtures unless they contain a considerable amount of fine dust.

From the tests on the action of static electricity, it appears that, at least in the case of the attrition mill, any static electricity that may be generated is dissipated so rapidly by leakage, which is due to the relatively high atmospheric humidity (Pennsylvania) that no potential is built up in the frame of the machine. Further, it appears to be comparatively difficult to ignite inflammable dusts in an attrition mill by means of static electricity. Nevertheless, every precaution should be taken to eliminate static electricity in the operation of any kind of mill, one good method being the grounding of the machine.

The moisture content of the material appears to have an important bearing on its inflammability. The less moisture the dust contains the more inflammable it is likely to be, and it is probable that there is a maximum moisture content above which the dust cannot be ignited.

Revolving dampers and relief valves as a means of prevention for the propagation of explosions were tried. Both were found of some value. In particular, it was found that a double

re-sliding damper does not appear to serve the purpose of a ... better than a single damper. (*U. S. CAPITALIZATION VALUE OF STEAM LEAKS, R. Von Fabrice. *Power*, vol. 47, no. 19, May 7, 1918, pp. 656-658, 1 chart.

SOME NOTES ON TURBINE BEARINGS AND THEIR LUBRICATION, Charles H. Bromley. *Power*, vol. 47, no. 21, May 21, 1918, pp. 734-736. An interesting collection of data taken from the author's loose leaf notebook.

BOILER SETTINGS—CHAIN GRATE STOKERS, Chas. H. Bromley. One of several articles on boiler settings for various boilers and types of stokers most suitable for the different coals. The chief purpose of the articles is to assist those in the Middle West and Northwest who are confronted with combustion problems by reason of the zone system for the distribution of bituminous coal enforced by the Fuel Administration. Several excellent chain-grate settings are shown in this article. (*Power*, vol. 47, no. 23, June 4, 1918, pp. 788-792, 6 figs.)

BOILER SETTINGS, Chas. H. Bromley. Data on boiler settings for various stokers under different kinds of boilers adapted to high-volatile coal. The writer claims that secondary arches are sometimes superfluous. Thus, secondary arches on Stirling boilers of the usual class are far from the fire and cannot exert an appreciable performance upon the fuel bed. It is therefore of no help in coking the coal, unless the grate is run too fast. This may explain the gradual abandonment of the secondary arches on these boilers. In some settings, however, a secondary arch may be useful for mixing the air and gases, provided the bridge wall is continued high enough to form a narrow passage between the end of the bridge wall and the end of the secondary arch. (*Power*, vol. 47, no. 22, May 28, 1918, pp. 760-762, 3 figs., 2 tables)

CONCRETE BOILERS NEXT. Now, according to the San Francisco *Chronicle*, cement may be used in the construction of boilers in the near future, as it is understood that an experiment will be made at the Union Iron Works. The report says that considerable figuring has been done and numerous sketches have been made, and that a boiler will be constructed shortly. It is stated that it is expected that with the exception of the boiler shell there will be but little change, and instead of one thick boiler sheet the new construction of shell is to consist of two thin sheets of steel, probably 1/4-in. in thickness, and these will be fastened together, leaving between them 2 or 3 in. of space, which will be filled with a high-grade cement. (*Power*, vol. 47, no. 23, June 4, 1918, p. 808)

NOTE SUR LA CORROSION DES TUBES DES CONDENSEURS PAR SURFACE ALIMENTÉS À L'EAU DE MER, G. Costeseque. *Revue Générale de L'Electricité*, 2 annee, tome 3, no. 18, May 4, 1918, pp. 647-650. Discussion of the corrosion in surface-condenser tubes supplied with sea water as a cooling medium.

*TUBE FAILURE IN WATER-TUBE BOILERS. An editorial presenting in an interesting manner a survey of the general state of our knowledge on tube failure in water-tube boilers. The article properly emphasizes the fact that water-tube explosions generally result in more damage to human life and health than to property, and that every precautionary measure available should be applied to minimize these accidents. (*Power*, vol. 47, no. 21, May 21, 1918, pp. 739-740.)

DESIGN AND LAYOUT OF CONDENSERS, D. D. Pendleton. *The Iron Trade Review*, vol. 62, no. 22, May 30, 1918, pp. 1361-1365, 5 figs. Paper presented at the recent meeting of the Engineers' Society of Western Pennsylvania. A practical discussion on the subject of selection of condenser equipment under various conditions, and the importance of providing the installation with proper auxiliaries.

SUPPORTING EFFECT OF BOILER HEADS, Neil M. Macdonald. The writer discusses the question as to whether the strength of the unbraced head should be added to the strength of the stays to find the allowable pressure in a boiler, especially in one of large dimensions and operating under high pressure.

In particular, and by way of illustration, he examines the case of a 72-in. by 18-ft. horizontal tubular boiler having a distance of 26 in. between the top of the tubes and the shell plate.

The area to be braced in this case is the area of a segment enclosed by lines drawn 3 in. from the shell and 2 in. from the tubes, or an area of 936 sq. in.

For the strength of the unbraced flat head he uses the Nichols formula, which, while experimental, is sufficiently accurate for the purpose. For a boiler head 1/2-in. thick and a material having a tensile strength of 55,000 lb. per sq. in. this formula gives a safe working pressure of 37 lb. per sq. in., so that if the boiler was to be designed for a safe working pressure of 125 lb. per sq. in. and the strength of the unstayed head be added, the bracing would be sufficient if good for $125 - 37 = 88$ lb. In accordance with this theory, if the factor of safety on the unbraced head was 8 and on the braces 6, the bursting pressure on the braced head would be $(37 \times 8) + (88 \times 6) = 824$ lb. per sq. in. The writer shows that this is absolutely wrong and that the real bursting pressure of the head is only the value of the strongest portion, which, in this case, is the braces, and is $88 \times 6 = 528$ lb. per sq. in., which gives a safe working pressure of 88 lb. per sq. in.

The writer, in his discussion, compares what happens in the boiler to the case of two walls joined by a rope fastened so that it cannot slip and capable of withstanding any pull up to 528 lb. As soon as the pressure rises above 296 lb., which is more than the weaker wall can stand by itself, the only thing that holds the wall from collapsing is the staying power of the rope. But when the pressure reaches 528 lb. the rope breaks, allowing the full load of 528 lb. to come on the weaker wall, and, as the latter can stand only 296 lb., both the rope and the wall must let go. This explains the case of the boiler with unstayed head.

The same argument applies to the staybolted furnace sheet of a vertical tubular boiler with the slight difference when the furnace sheet proper is stronger than the staybolts. It also applies to the stay bolting of a cone top in a submerged vertical tubular boiler and to the flat firebox sides of a locomotive-type boiler. The writer sums up the subject by stating that a braced or staybolted portion of a boiler is no stronger than its strongest part, and on no account should the strength of the braces or staybolts be added to the strength of the plate and their sum considered the strength of that portion of the boiler. (*Power*, vol. 47, no. 21, May 21, 1918, pp. 733-734, *g*)

STRESSES IN TURBINE BLADING, Gerald Stoney. The blading in steam turbines is exposed not only to stress due to centrifugal force, but also to stress due to pressure of steam on the blades, and to vibratory stresses.

The stress due to centrifugal force is nearly a function of the weight of the blade and speed of rotation and is a steady stress. The writer gives formulæ for the centrifugal stress in brass and steel blades and asserts that due regard in considering it must be had to the fact that in some types of blade fixing the strength of the fixing is less than the tensile strength of the blade, and often the blade is cut away at the root to provide for the blade fixing. Furthermore, in some types of construction the yield point at which the blade begins to draw out of its fastening is reached considerably before the yield point of the material of the blade, which is especially liable to occur with blades of brass or other alloy which have a much higher coefficient of expansion than the steel of the turbine rotor. (In this connection, more data are given below.)

The next stress on the blades is that due to the pressure of the steam on the blades, which is also the force that drives the turbine. The writer indicates a method which has been found convenient in practice.

In designing a turbine the following quantities, among others, are generally known:

R = revolutions per minute

Q = maximum pounds steam per hour

$\alpha = u/c$ = velocity ratio or ratio of blade speed u to steam speed c in feet per second

η_1 = blade efficiency.

In his calculations the author introduces also the unit of blade width, w, that is, width of a row of blading measured axially in the turbine. In this way he shows that the force on each blade is:

$$t = \frac{Q\eta_1 Rbw}{168\alpha^2} \times 10^{-6} \ldots\ldots\ldots\ldots\ldots [3]$$

where b is a constant depending on the type of blading (in impulse blading b is generally between 0.5 and 0.6 and in reaction blading it is between 0.6 and 0.7).

If Z is the resistance modulus of the blade section when 1 in. wide and f_s is the stress on the blades due to steam pressure, then the moment is $f_s Z w^3$, and is equal to $\frac{th}{2}$ Putting this value for t into the above equation, we have:

$$\frac{h}{w^2} = 336 \times 10^6 \frac{\alpha^2 f_s Z}{Q\eta_1 Rb} \ldots\ldots\ldots\ldots\ldots [4]$$

Values of $\frac{\alpha^2}{\eta_1}$ for impulse blading for various values of α derived from Fig. 11 are given in Fig. 12. Strictly speaking, these should be corrected for leakage; but in neglecting this correction we are keeping on the safe side, and in a modern turbine the leakage is small. This seems a difficult equation to work with; but in practice it must be remembered that usually the velocity ratio and blade shape are constant throughout the whole or a large part of the turbine, and therefore α, η_1, b and Z are constant; so that

$$\frac{h}{w^2} = C\frac{f_s}{QR} \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

The total tensile stress on the blade is then given by $f = f_s + f_c$; and here a distinction must be made between the strength of the blade and the strength of the way in which it is fixed into the rotor; in other words, of the blade fixing.

The stress due to steam pressures in the blade, or f_s, causes bending of the blade, and this combined with the centrifugal force f_c gives the stress which must be allowed for at the weakest section of the root of the blade. On the other hand, so far as pulling the blade out of the rotor is concerned, only the centrifugal force f_c must be taken into account.

As regards the factors of safety, much higher factors must be allowed for the stresses due to bending where there is pressure admission on account of intermittent action of the steam. In the case of partial admission the value of h/w^2 must be multiplied by the proportion of the circle occupied by nozzles. Actually, the suitable blade widths can be seen at once when the blade heights are known.

The writer mentions another method applicable when partial admission is used and the velocity of the steam is above the critical velocity. This method is based on the formulæ of Rankine and Rateau, namely, that the flow of steam in pounds per second is approximately proportional to the absolute pressure in pounds per square inch.

The writer believes that the cutting away of the sides of the blades for fixing them into a dovetail curve in the rotor weakens the blade against bending stress much less than might be supposed. In fact, he claims that in some cases this cutting away even increases its theoretical stress, as the resistance modulus of the blade action $Z = I/\sigma$, where I is the moment of inertia of the blade and σ is the distance of the

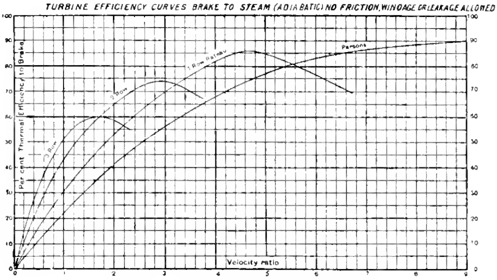

FIG. 11 TURBINE EFFICIENCY CURVES

edge of the blade through the center of gravity. Cutting away the edges reduces σ largely, and I only a little, as the edges are thin, so that a certain amount of cutting away actually increases the strength of the blade. In practice, however, the amount of cutting away is so large (in order to provide sufficient bearing surface to take a centrifugal force) as to weaken the blade.

In the preceding discussion which applied to impulse turbines, only the tangential force on the blades has been considered, while the axial force parallel to the axis of the turbine and due to drop of pressure in the moving blade has been neglected, since in impulse turbines it is generally small in amount.

But in reaction or Parsons blading the drop of pressure across the moving blades is considerable and the axial stress large, in fact, under ordinary conditions is equal to or rather more than the tangential.

With such blading where there is equal expansion of the steam in the fixed and moving blades we have the equation

$$t = \frac{Q\eta_1 Rbw}{84\alpha^2} \times 10^{-6} \ldots\ldots\ldots\ldots\ldots [7]$$

for the tangential force only. Here α is the true velocity ratio or the ratio of the blade speed to the steam speed in either the fixed or the moving rows. In some books the velocity ratio is taken as if the whole of the expansion were in the fixed row, as in the impulse turbine, this latter velocity being, therefore, $1/\sqrt{2}$ of the above value of α.

Let T be the tangential force on the blading and L the axial,

Δp being the drop of pressure across either moving or fixed row, and V the volume of steam in feet per second.

$$T = \frac{2 r_t V \Delta p}{u}$$

and

$$L = A \Delta p$$

A being the area of the annulus. Therefore:

$$\frac{T}{L} = \frac{2 V r_t}{u A} = \frac{2 r_t \sin\theta}{\alpha} \quad \ldots\ldots\ldots\ldots\ldots\ldots [8]$$

since V / A = axial velocity of the steam, or $c \sin\theta$, θ being the blade angle; and the forces on each blade have the same

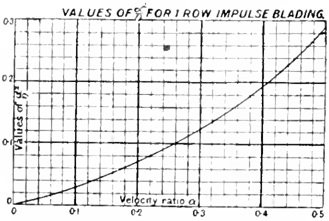

FIG. 12 $\frac{\alpha^2}{\eta}$ FOR IMPULSE-TURBINE BLADING

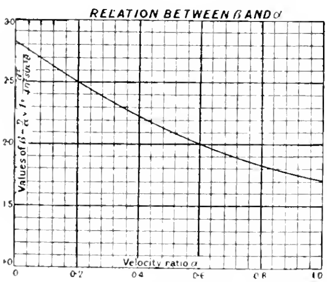

FIG. 13 $\frac{\beta}{\alpha}$ FOR REACTION-TURBINE BLADING

ratio. The resultant force on the blade, n, is then the resultant of these two forces, or:

$$n = t \sqrt{1 + \left(\frac{\alpha}{2 r_t \sin\theta}\right)^2}$$

$$= \frac{QRbwr_t}{84 \times 10^6 \alpha^2} \sqrt{1 + \left(\frac{\alpha}{2 r_t \sin\theta}\right)^2}$$

Calling

$$\frac{r_t}{\alpha} \sqrt{1 + \left(\frac{\alpha}{2 r_t \sin\theta}\right)^2} = \beta$$

$$n = \frac{QRbw}{84 \times 10^6 \alpha} \beta \quad \ldots\ldots\ldots\ldots\ldots\ldots [9]$$

From this it follows that:

$$\frac{h}{w^2} = 168 \times 10 \frac{tZ\alpha}{QRb\beta} \quad \ldots\ldots\ldots\ldots\ldots [10]$$

Fig. 13 gives the relation between β and α, derived from Fig. 11, θ being taken as 20 deg.; and since, of course, the minimum value of α in any section of the turbine must be taken, it is seen that between the values of $\alpha = 0.4$ and $\alpha = 0.6$, which are the usual minimum values in modern turbines, the value of β is 2.15, so that:

$$\frac{h}{w^2} = 78 \times 10 \frac{tZ\alpha}{QRb} \quad \ldots\ldots\ldots\ldots\ldots [11]$$

which gives the total stress on the blades due to the combined effect of pressure drop and reaction.

Hitherto no account has been taken of the stiffening effect of the shrouding or lacing of the blades. This is because shrouding riveted on to the top of the blades cannot be considered rigid for small movements. Shrouding would increase the strength of the blade if it could be rigidly fixed to the blades by silver soldering or bracing, but this is difficult to accomplish. (*Engineering*, vol. 105, no. 2730, April 26, 1918, pp. 447-448, 3 figs., *ta*)

Thermodynamics

LOSSES OF HEAT THROUGH ENGINEERING AND BUILDING MATERIALS, R. B. Fehr, Mem.Am.Soc.M.E. Report on the thermal testing plant at the Engineering Experiment Station of the Pennsylvania State College.

This plant was designed and built for the purpose of studying the loss of heat through various engineering and building materials. Thus far the plant has produced data on the total transmission in various materials and has emphasized the importance of studying the effect of velocity, humidity and surface resistance. The following program of experiments with the present apparatus was adopted:

1 Study of temperature gradients through glass
2 Calibration of corkboard test box (5 ft. cube)
3 Transmission of heat through glass
4 Transmission of heat through air spaces formed by building paper.

The writer gives brief résumé of the theory of heat transmission and a rather elaborate description of the apparatus, methods of testing and method of calibration of the corkboard box.

As regards the results themselves, it appears that in the case of glass, as well as other poor insulators, practically all high resistance is to be found in the so-called surface resistance. It appears also that in spite of their entirely opposite insulating properties corkboard and glass exhibited a rather remarkable agreement in their value of k_1 (radiation and convection effect of surface on warm side or surface transmission in B.t.u. per 24 hours per sq. ft. per degree difference), k_2 (surface transmission on cool side), and K (total surface transmission for both sides), the values at 70 deg. difference of temperature being respectively, 59, 43 and 25 for corkboard and 90, 46 and 30 for glass. The higher values for glass are probably due to its smooth surface and transparency to radiation from within the test box.

Rather interesting tests were carried out on air spaces formed by building paper. The curves in the lower half of Fig. 14 show that there is an appreciable increase in the value of u, which is transmission in B.t.u. per 24 hours per sq. ft. per deg. fahr. with increase of temperature difference, as was also found by the Bureau of Standards. The curves in the upper part of Fig. 14 were obtained by plotting the values of the lower half as percentages of the fall of u for one layer of paper at a particular temperature difference. These curves show that for the ordinary differences of temperature found in heating and refrigerating and for ½-in. dead air spaces, the total transmission varies inversely as the number of layers of paper; in fact, the transmission falls off more rapidly, the statement implies, and, therefore, the rule will give results on the safe side for insulation problems.

The gradual approach to the theoretical curve (derived from

the above rule) as the temperature difference increases, leads to the conclusion that for temperature differences higher than, say, 100 deg. fahr., the greatly increased effect of radiation would render this simple rule useless. This fact is in line with the one recently established by the Bureau of Standards that for high-temperature insulation air spaces are not as effective as solid walls, because of transparency of air to radiation. Nevertheless, the writer comes to the conclusion that properly arranged inexpensive air spaces can be made as effective as the same thickness of the best insulating material on the market.

Attention is also called to the following conclusions:

1 More attention should be given to the matter of surface resistances, which, in the cases of glass or other poor insulators, constitute practically the total resistance.

2 The velocity of the air on the warm side of the wall probably exerts as much influence on the total surface resistance as the velocity of the air on the cool side.

3 The total surface transmission (both sides) for corkboard, glass and building paper, in the usual ranges of temperature for conditions involving slight air movements, is not far from 25 to 30 B.t.u. per 24 hours per sq. ft. per deg. fahr., and in the case of poor insulators rises to about 50 for a moderate velocity on the warm side and a higher velocity (1000 ft. per min.) on the cool side. (Report on the Thermal Testing Plant for 1916-1917, *The Engineering Experiment Station Bulletin No. 24. The Pennsylvania State College Bulletin*, vol. 12, no. 4, February 15, 1918, 25 pp., 6 figs., *ep*)

Varia

Neville Island Gun and Projectile Plant. The proposed plant will be built and operated for the Government by the U. S. Steel Corporation and will be in charge of a new organization called the U. S. Steel Corporation Ordnance Department, with John Ries, chairman, and L. E. Thomas, chief engineer.

One of the great problems in connection with the building of the new plant is that of securing labor and of housing the many hundreds of men who will be engaged for two years or more on construction work. Tentatively, it is proposed to establish a model town at the lower end of Neville Island with houses for employees of the arsenal as well as for operating officials at the plant. It is not unlikely that one or two bridges will be built across the Ohio River to connect Neville Island with the tracks of the Pennsylvania Lines West, and it is possible that one or two bridges will be erected across the back channel of the Ohio River connecting the island with the Pittsburgh and Lake Erie tracks.

Nothing has been determined so far as to the number and size of the steel works or other units that will be built, there being one stack now with a capacity of 450 tons per day; neither has the number of electric and open-hearth furnaces been determined at yet. CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

BOOK NOTES

The Chemical Analysis of Iron. A Complete Account of All the Best Known Methods for the Analysis of Iron, Steel, Pig-Iron, Alloy Metals, Iron Ore, Limestone, Slag, Clay, Sand, Coal and Coke. By Samuel Alexander Blair. Eighth Edition. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 6x9 in., 318 pp., 102 illus., 2 tables. $5.

In this work the aim of the author has been to assemble in a single volume descriptions of the various methods and special apparatus which have been shown to be of real value to the iron analyst. Since the appearance of the seventh edition, in 1912, so many improvements have been developed in methods and the alloy metals have become so increasingly important that it has been found necessary practically to rewrite the book to bring it down to date. The table of atomic weights gives the values recommended by the Committee for 1918, and the table of factors has been revised to correspond with the new values.

Analysis of Financial Statements. By Richard P. Wilson and Harry J. Carpenter. La Salle Extension University, Chicago (copyright 1918). Paper, 6x9 in., 38 pp., 4 illus.

In this book the methods and principles of these analyses are described and illustrated by typical examples.

The Automobile Repairman's Helper. A Pocket Book for the Mechanic, Owner, Chauffeur and Student. By S. T. Williams. U. P. C. Book Co., Inc., New York (copyright 1918). Flexible cloth, 5x7 in., 438 pp., 322 illus. $2.50.

The object of the compiler has been to give the best method of doing each particular job of repairing and also to explain the proper sequence in which the various operations should be done. The methods described are thought to cover every trouble likely to be found in all the standard cars.

A Bibliography of Municipal Utility Regulation and Municipal Ownership. By Don Lorenzo Stevens. Harvard University Press, Cambridge, 1918. Cloth, 6x9 in., 410 pp. $4.

An extensive bibliography of material published in English, brought down to the end of 1916. Covers electric, gas, water and traction utilities, listing the material which the author considers of practical value, after an extensive study of the field. The entries are classified and annotated, and an index of subjects and authors is provided.

The Coal Catalog. Combined with Coal Field Directory for the Year 1918, Containing Explanatory Articles on Rank, Usage, Analysis, Geology, Storage and Preparation of Coals, together with a Typical Section of the Productive Formation of Each Coal Mining State in the Union, Maps Showing the Various Mining Districts or Fields, Descriptions of the Seams Mined . . . List of Seams Producing Coal Suitable for Each Industrial Purpose, etc., and a Directory of all the Coal Mines in the United States. . . . Keystone Consolidated Publishing Co., Inc., Pittsburgh (copyright 1918). Cloth, 9x12 in., 671 pp., 90 illus., 25 maps. $25.

A remarkably complete compendium of the coal industry of the United States and Canada, in which is collected the information needed by producers and users.

Digest of Publications of Bureau of Standards on Electrolysis of Underground Structures Caused by the Disintegrating Action of Stray Electric Currents from Electric Railways. Prepared by Samuel S. Wyer. Paper, 7x10 in., 96 pp.

Summarizes by verbatim quotations the essentials of the extensive laboratory and field investigations on this subject which the Bureau of Standards has published up to August 22, 1916. The quotations selected have been classified, and the compiler has added editorial notes. Copies may be procured from the Bureau of Standards, Washington, D. C.

Direct Costs of the Present War. By Ernest L. Bogart.

The Early Effects of the European War Upon the Finance, Commerce, and Industry of Chile. By L. S. Rowe. (Carnegie Endowment for International Peace, Division of Economics and History. Preliminary Economic Studies of the War.) Oxford University Press, New York, 1918. Paper, 7x10 in.

These two pamphlets, belonging to a series of economic studies of the effects of the European War, and undertaken by the Carnegie Endowment for International Peace, discuss separate phases of the question. Professor Bogart's summary of the cost of the war to each participant covers only the direct financial outlays of the governments, compiled from the best available reports. Dr. Rowe gives an account of the immediate effects of the war in the period of the fall of 1914 and the spring of 1915, based on a personal investigation during the latter year.

Dyke's Automobile and Gasoline Engine Encyclopedia. Treating on the Construction, Operation and Repairing of Automobiles, and Gasoline Engines. Also Trucks, Tractors, Airplanes and Motorcycles. By A. L. Dyke. Seventh edition, revised and enlarged, containing dictionary and supplements on the Ford, Packard and airplanes. Published by the author, St. Louis, Mo. (copyright 1918). Cloth, 7x10 in., 864 pp., 515 charts. $3.50.

Presents in clear, simple and concise form the principles upon which gasoline engines and automobiles are built and operated. Sections are included on repairing, adjusting and driving, together with much miscellaneous information of value to automobile engineers and drivers. Over three thousand illustrations accompany the text.

Elements of Machine Design. By Henry L. Nachman. First edition. John Wiley & Sons, Inc., New York, 1918. Cloth, 6x9 in., 244 pp., 275 illus., 22 tables. $2.

A classroom text on the subject of elementary machine design, for students in technical institutes.

Elements of Sanitary Engineering. By Mansfield Merriman. Fourth edition, revised with the assistance of Richard M. Merriman. John Wiley & Sons, Inc., New York, 1918. Cloth, 5x9 in., 250 pp., 47 illus., 17 tables. $2.

A textbook intended to present the subject clearly in the smallest possible space, and to give greater prominence to fundamental principles than to details of construction and operation. The present edition has been revised, and fourteen new pages of text have been added.

Employment Department and Employee Relations. By F. C. Henderschott and F. E. Weakly. La Salle Extension University, Chicago (copyright 1918). Paper, 6x9 in., 60 pp., 20 illus., 4 tables.

Suggestions based on methods in use by various corporations. Contents: Selection of the Employee, the Labor Supply, Promotions and Transfers, Progressive Scale of Promotion Based on General Intelligence Requirements, Employee Records as a Basis for Promotion, Annual Survey of Employees, the Principle of Transfer, the Vocational Laboratory, Job Analysis, Labor Turnover, Educational and Welfare Work.

A Handbook of Rocks.. For Use without the Microscope. With a Glossary of the Names of Rocks and of other Lithological Terms. By James Furman Kemp. Fifth edition, revised. D. Van Nostrand Co., New York, 1918. Cloth, 6x10 in., 272 pp., 41 illus., 75 tables. $1.50.

Professor Kemp has attempted to avoid the difficulties usually met by students, by mentioning and emphasizing only those characteristics which a beginner with preliminary training in mineralogy can observe and grasp. An extensive glossary is included in the work.

Eye Hazards in Industrial Occupations. A Report of Typical Cases and Conditions, with Recommendations for Safe Practice. By Gordon L. Berry. National Committee for the Prevention of Blindness, New York, 1917. Paper, 6x9 in., 145 pp., 51 illus. $0.50.

A survey of the hazards to the eyes in industrial occupations in the United States, with recommendations and suggestions for minimizing them.

General Lectures on Electrical Engineering. By Charles Proteus Steinmetz. Fifth edition, compiled and edited by Joseph LeRoy Haden. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6x9 in., 242 pp., 50 illus., 1 por., 1 table. $2.50.

A series of descriptive, non-mathematical lectures on the problems of the generation, control, transmission, distribution and utilization of electric energy. The present edition has been largely rewritten to include the changes that have taken place in the electrical industry during the last eight years.

How to Become a Wireless Operator. A Practical Presentation of the Theory of Electrical Waves, their Propagation, and their Adaptation to Wireless Communications, including Simple and Clear Instructions on how to operate Wireless Devices and how to comply with Government Requirements for Operators. By Charles B. Hayward. American Technical Society, Chicago, 1918. Cloth, 6x8 in., 298 pp., 196 illus., 1 pl., 9 tables.

This work does not discuss the history nor the mathematics of radiotelegraphy, but is intended for those wishing to become proficient operators. Designed for individual study.

An Introduction to Statistical Methods. A Textbook for College Students; a Manual for Statisticians and Business Executives. By Horace Secrist. The Macmillan Co., New York, 1917. Cloth, 5x8 in., 482 pp., 28 pl., 95 tables. $2.

A study of the principles governing the collection, analysis, and synthetic treatment of numerical data, intended to supply the need for a fundamental treatment of the methods of statistical investigation and interpretation. The methods discussed are of general application, and are accompanied by illustrations drawn chiefly from economic and business fields. The treatment is non-mathematical.

Machine Design. A Manual of Practical Instruction in Designing Machinery for Specific Purposes, Including Specifications for Belts, Screws, Pins, Gears, etc., and many Working Hints as to Operation and Care of Machines. By Ernest L. Wallace. American Technical Society, Chicago, 1918. Cloth, 6x8 in., 157 pp., 90 illus., 2 pl., 9 tables.

A simple treatment of the subject, adapted for home study and intended for use by machinists, draftsmen and apprentices.

Manual of Forestry for the Northeastern United States. Being Vol. 1 of Forestry in New England revised. By Ralph Chapman Hawley and Austin Foster Hawes. Second edition. John Wiley & Sons, Inc., New York, 1918. Cloth, 6x9 in., 281 pp., 64 illus., 50 tables. $2.

The first of the two volumes dealing with the specific forestry problems of New England, but applicable also to conditions in neighboring states. This volume presents, in the simplest and least technical form possible, a brief survey of the whole field of forestry, for the use of woodland owners.

Metal Statistics 1918. Eleventh annual edition. The American Metal Market Co., New York (copyright 1918). Cloth, 4x6 in., 427 pp. $0.50.

Tables showing production, prices, imports, exports, etc., of iron ore, coke, iron and steel products, copper, tin, lead, spelter, aluminum, antimony, silver and other metals. In most cases the statistics cover a number of years.

The Modern Gasoline Automobile. Its Design, Construction, Operation and Maintenance. A Practical, Comprehensive Treatise Explaining All Principles Pertaining to Gasoline Automobiles and Their Component Parts. By Victor W. Pagé. Revised and enlarged. The Norman W. Henley Publishing Co., New York, 1918. Cloth, 6x9 in., 1032 pp., 1000 illus., 11 charts. $3.

This edition has been brought up to date by careful revision and the introduction of supplementary matter on ignition, tractors, power transmission, carburetion, etc.

Sulphuric Acid Handbook. By Thomas J. Sullivan. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Flexible ..., 5x7 in., 239 pp., 35 illus., 57 tables. $2.50.

The author has collected in one volume of convenient size the chemical and mechanical data of practical value to makers and users of sulphuric acid in American industries.

Military Observation Balloons (Captive and Free). A Complete Treatise on Their Manufacture, Equipment, Inspection and Handling, with Special Instructions for the Training of a Field Balloon Company. By Emil J. Widmer. D. Van Nostrand Co., New York, 1918. Flexible cloth, 5x8 in., 171 pp., 38 illus., 3 pl. $3.

This manual is based on the balloon manual of the German army, and the equipment and drill in use by the Germans at the beginning of the war. It gives a complete survey of the field.

Patenting and Promoting Inventions. By Mois H. Avram. Robert M. McBride & Co., New York, 1918. Cloth, 5x8 in., 166 pp. $1.50.

Written for the inexperienced inventor, this book gives sound, practical advice on the proper method of securing, protecting and promoting commercial patents.

Principles of Mechanism. By Walter H. James and M. C. Mackenzie. First edition. John Wiley & Sons, Inc., New York, 1918. Cloth, 5x8 in., 241 pp., 246 illus. $1.50.

Presents the elementary principles of mechanism without the use of advanced mathematics. Intended especially for trade schools, etc.

Principles of Ocean Transportation. By Emory R. Johnson and Grover G. Huebner. D. Appleton & Co., New York, 1918. Cloth, 6x9 in., 513 pp., 68 illus., 3 folded pl., 9 maps (two folded), 2 folded charts, 18 tables. $2.50.

A systematic, comprehensive review of the whole subject, including ocean couriers and their services, ocean conferences, ocean rates and fares, and the principles and practices of Government aid and regulation of ocean shipping. The book does not attempt to treat the various questions exhaustively but seeks to present the essential facts for students and business men.

Radiometric Apparatus. For Use in Psychological and Physiological Optics. Including a Discussion of the Various Types of Instruments That Have Been Used for Measuring Light Intensities. By C. E. Ferree and Gertrude Rand. Published as Psychological Monographs, No. 103. Paper, 7x10 in., 65 pp., 6 illus. $0.75.

After a discussion of various types of instruments that have been used for measuring light intensities, and the advantages and disadvantages of each, the authors describe the apparatus which they have found most desirable.

A Text-Book of Laying Off. The Geometry of Shipbuilding. By Edward L. Attwood and I. C. G. Cooper. Second edition. Longmans, Green & Co., London, 1918. Cloth, 6x9 in., ... pp., ... illus., 2 plates. $2.

This work is intended to provide students of naval architecture and ship draftsmen with a description of the processes and methods used in various shipbuilding yards and centers. The second edition has been revised with a view to greater clearness and some additions have been made to the text.

A Treatise on Roads and Pavements. By Ira Osborn Baker. Third edition, rewritten and enlarged. John Wiley & Sons, Inc., New York, 1918. Cloth, 6x9 in., 666 pp., 235 illus., 83 tables. $4.50.

Dr. Baker's work is a discussion of the engineering principles involved in the construction of country roads and city pavements, intended for the designer and inspector rather than for the contractor. Attention has been given to materials and forms of construction that affect the quality and cost of roadway rather than to methods of doing the work. This third edition has been thoroughly revised and entirely rewritten. Five chapters of minor importance have been dropped to make room for an equal number of new ones, and the number of illustrations have been greatly increased.

THE ECONOMICAL USE OF FUEL

A Symposium Contributed to the Worcester Meeting of The American Society of Mechanical Engineers, June, 1918

TOPICAL INDEX

C. 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

THE ECONOMICAL USE OF FUEL

At the Spring Meeting of The American Society of Mechanical Engineers, held at Worcester, Mass., June 4-7, 1918, sessions were held for the discussion of the all-important subject of fuel economy. In preparation for this session the Committee on Meetings invited the Fuel Conservation Committee of the Engineering Council to formulate a set of questions which was sent out to a list of fuel engineers throughout the country, and over 60 of whom responded with contributions.

The country now faces a coal shortage of 80,000,000 tons this year. We need 100,000,000 tons more this year than last, or 220,000,000 tons more than ever before mined in one year. Military draft has taken about 35,000 miners and there is a serious shortage of open-top equipment to haul coal. Every fuel user must exert his greatest effort to effect fuel economy and every engineer owes it as a public duty to render his utmost assistance to this end. In no small measure the symposium which follows should help in the conservation movement.

CONTRIBUTED DISCUSSION

On this and the following pages are published selections from the discussions received in response to the questionnaire issued for the Fuel Session of the Spring Meeting. These are grouped under the several headings to which the subject matter applies. In preparing the material for publication duplicate matter was eliminated so far as possible, and the whole is printed in concise form, so that it may be used for reference purposes with the greatest possible facility.

The topics upon which discussion was solicited are as follows:

1 What Are the Economic Effects of Impurities in Coal?

2 To What Extent Is Fuel Oil Likely to be Used as a Substitute for Coal?

3 How Can Soft Coal Be Burned Without Smoke in Marine Boilers?

4 What Are the Possibilities in the Direction of the Utilization of Anthracite Wastes?

5 What Instruments Are Useful and Desirable in the Boiler Room as Aids in Saving Coal?

6 What Is Essential to the Economical Operation of Hand-Fired Boiler Furnaces When Using Soft Coal?

7 To What Kinds of Plants and Coals are the Different Types of Mechanical Stokers Respectively Adapted, and What Is the Limiting Factor to Their Use in the Small Plant?

8 What Experience Have You Had in the Use of Wood as Fuel? To What Extent Is Wood Available as a Fuel?

9 What Coal Economies Can Be Effected in Residence Heating?

10 What Coal Economies Can Be Effected in the Small Steam Plants?

11 What Experiences Have You Had With the Storage of Coal?

12 (*a*) To What Extent and Where Will the Gas Producer be Used to Produce Economies?

12 (*b*) To What Extent is Natural Gas Being Used as a Fuel for Power Purposes?

12 (*c*) What is the Relative Economy of the Locomotive of 1900 and Today?

12 (*d*) What Proportion of the Coke is Made in By-product Ovens?

12 (*e*) What are New and Important Developments in Methods of Burning Coal?

12 (*f*) What Economies have Resulted from Recent Practice in Making Brick Settings Leakless?

12 (*h*) Is Automatic Air Supply Correctly Proportioned to Coal Supply Possible?

12 (*l*) Miscellaneous—School Heating—Insulation—Smoke Prevention.

Preceding the contributions on the specific topics of the questionnaire, are three discussions of an introductory character which were presented at the meeting by their authors. The first, by David Moffat Myers, Advisory Engineer of the Fuel Administration, outlines the work of fuel conservation which is being undertaken by the Government: the second, by E. L. Cole, of the Fuel Administration of Pennsylvania, tells of the effective work in that state, the source of our anthracite supply, to secure clean coal; and the third discussion, by Alfred C. Bedford, President of the Standard Oil Company, deals with the supply of fuel oil.

In presenting his discussion, Mr. Cole interspersed his remarks with definite statements regarding operators and dealers who had been penalized for delivering inferior coal, and left the impression strongly in the minds of his audience that the Pennsylvania Fuel Administration had the question of a proper quality for the anthracite supply well under control. Following his remarks resolutions were passed, given on page 616, in which those present warmly pledged their support to the Pennsylvania Administrator and heartily approved his accomplishments.

THE GOVERNMENT'S PLAN FOR FUEL CONSERVATION

By David Moffat Myers[1]

As a member both of The American Society of Mechanical Engineers and of the United States Fuel Administration, it gives me pleasure to report the positive and progressive measures which have been taken by the Government for effecting fuel conservation in power plants and on railroads since the last annual meeting of this Society, in December, 1917. At that meeting, in my paper on Preventable Waste of Coal in the United States, a saving of 50 to 100 million tons per year was shown to be possible, together with suggestions as to measures for effecting this economy. I am not overstepping the mark when I state that the national program which I will outline to you, was planned, presented and organized by members and committees of the national engineering societies.

As a result, a Fuel Engineering Division was formed in the United States Fuel Administration in Washington, under its Bureau of Conservation. This division comprised two depart-

[1] Advisory Engineer of the U. S. Fuel Administration. Mem. Am. Soc. M. E.

ments—Railroads and Industries; the latter covering all power plants not belonging to railroads. The railway department was placed in charge of one of the highest authorities in the field in the country, Major Edward C. Schmidt, U. S. R., Mem.Am.Soc.M.E., who was transferred by Secretary Baker to the U. S. Fuel Administration. Major Schmidt devised and developed a plan of organization which was the work of a master mind. It was authorized by the Fuel Administration and endorsed by Mr. McAdoo's special representative. The Railway Administration determined to administer the program through its own organization, whereupon Major Schmidt was given over to the other administration, for the continuance of the work.

At present, therefore, the Fuel Engineering Division devotes itself exclusively to the work of conservation of fuel in stationary power plants, and in the efficient use of steam after its generation. The organization comprises the central office at Washington, with an administrative engineer appointed (or to be appointed) in each coal-using state, attached to the Federal Fuel Administration of that state. The Administrative Engineer has a consulting board of competent engineers, and a staff of technical and clerical assistants and inspectors.

The plan of organization involves centralization on essential fundamentals only. These are uniform for all states. All other features are localized and extremely elastic in their numerous ramifications. This adopted principle renders the plan workable and effective under widely varying local conditions and circumstances.

The fundamentals of the national program are as follows:

a Personal inspection of every power plant

b Rating and classification of every power plant in the country, in five classes, depending upon the thoroughness with which the owner conforms to the recommendations of the U. S. Fuel Administration

c At the discretion of the Federal Fuel Administration, the supply of coal to any needlessly wasteful plant may be curtailed or stopped.

The plan is now in operation in Pennsylvania, the largest coal-consuming state, and also in Connecticut. Other states which have come in but in which the Administrative Engineer is not yet appointed, are Massachusetts, New York, New Jersey, Illinois, Michigan, Wisconsin, Indiana and Missouri.

For the office of Administrative Engineer, men are required of great organizing and administrative ability. For New York State, Mr. Edward N. Trump, Mem.Am.Soc.M.E. and vice-president of the Solvay Process Company, has patriotically accepted the nomination. Mr. Thomas R. Brown, the first Administrative Engineer actually appointed, is in charge of the western district of Pennsylvania. The second appointment was that of Mr. W. R. C. Corson for Connecticut, an officer of the Hartford Steam Boiler Insurance Company.

The standard recommendations of the United States Fuel Administration are substantially as follows:

a Fuel. That means be provided for measuring and recording fuel used each shift or day

b Water. That boiler feedwater be heated by exhaust steam or waste heat, and measured

c Air Supply. That a correct amount of air be supplied to the fuel, and that proper means be provided for measuring and regulating the draft

d Clean Heating Surfaces. That boiler heating surfaces be kept clean inside and out

e Boiler and Furnace Settings. That the furnace and setting be kept in good repair, and free from air leakage

f Insulation. That exposed steam surfaces wasting heat by radiation be covered with suitable insulating material

g Engine-Room and Heating System. That wherever possible, exhaust steam be utilized to the exclusion of direct steam from the boilers. (The plant should be designed and operated to produce no more exhaust than can be efficiently utilized in heating and process work)

h Supervision. (1) That a competent employee or committee be detailed to supervise the work of fuel conservation in the boiler and engine plants; and (2) that a competent committee be appointed in charge of the work of fuel conservation in the buildings and shops outside of the power plants.

To assist in this work, the United States Fuel Administration has prepared a fifty-minute film of moving pictures, showing good and bad operation in the steam-boiler plant, methods of testing boilers, fuels, etc. These pictures will be available to each state, in connection with their publicity and educational propaganda.

The Fuel Administration is also preparing a series of official bulletins on engineering phases of steam and fuel economics. Some of these are now in press.

They will include: Boiler and Furnace Testing; Flue-Gas Analysis; Saving Steam in Heating Systems; Boiler-Room Accounting Systems; Saving Steam and Fuel in Industrial Plants; Burning Fine Sizes of Anthracite; Boiler-Water Treatment; Oil Burning; and Stoker Operation.

In addition to this service, a list of competent engineers has been prepared in Washington for each state, and is available for use of the local administration. As the work develops, still further constructive assistance is contemplated for helping owners to bring their plants up to a high plane of economy.

LIMITING COAL IMPURITIES IN PENNSYLVANIA

By E. L. Cole[1]

Prior to the world war the capacity of the bituminous and anthracite mines in the United States to produce fuel was so much in excess of the demand that competition was an ample and certain factor in assuring the marketing of coal containing only a minimum of impurities.

With the steadily increasing demand for fuel, caused by the rapid development of war industries, there was a noticeable increase of the amount of impurities in anthracite and bituminous during the winter months of 1917.

These facts were known to the Fuel Administration, but because of the clamor among consumers, domestic and industrial, which was accentuated by weather conditions, for any sort of coal, action was deferred at that time. However, friendly suggestions were made to operators in the hope that the quality of coal would show improvement.

It was a vain hope.

During the Arctic-like weather of the second half of last winter the demand for coal skyrocketed to a point never before reached in this country. At the same time, the quality decreased with amazing rapidity, aggravating the existing fuel famine to a degree not readily credible.

The tonnage of inferior coal that was delivered in January was so large as to cause the Fuel Administration to take action. Dr. Garfield, National Fuel Administrator, assigned Mr. James Neale, of his staff, to assist the Pennsylvania Administration in providing and applying remedial measures in the anthracite fields.

[1] Secretary Conservation Division, Federal Fuel Administration for Pennsylvania.

Mr. Neale conferred with Mr. William Potter, State Fuel Administrator for Pennsylvania. With the aid of three gentlemen, who are the Fuel Chairmen in Luzerne, Lackawanna and Schuylkill Counties (Messrs. Tudor R. Williams, A. C. Campbell and Baird Halberstadt), an investigation was carried on into the amount of impurities being shipped to market.

The Fuel Administration then formulated rulings limiting the percentage of slate, bone and under sizes that would be permitted by the Government in all sizes of anthracite. Inspectors were appointed in the three counties mentioned with authority to condemn all coal found below standard. The writer was directed to supervise the inspection of coal at destination points within the State.

Effectiveness of Inspection and Penalties Imposed

The effectiveness of the inspection at the mines and destination points may be indicated by the report for May. These show that less than one-half of one per cent of the daily anthracite production of more than a quarter million tons was condemned by the Federal Inspectors for the month of May. This coal was condemned at the mines, and reprepared for delivery. The vast improvement can be better visualized when it is recalled that more than 50 per cent of the marketed tonnage during January and February contained excessive amounts of impurities.

During the inspection at destination, a car of buckwheat, containing 45 per cent of impurities, was delivered at a textile mill in Philadelphia. The fireman was unable to keep steam above 55 lb., normal steam pressure being 80 lb. Production at the mill fell off 30 per cent and the cost of removing ashes increased 300 per cent. The coal company was compelled to rebate to the mill owner 50 per cent of the cost of the coal, together with an equal percentage of the freight and cartage costs.

Operators who deliver coal containing excessive amounts of impurities have been subjected to various penalties. Some cars were ordered hauled to the dumping grounds in Philadelphia; others were donated to hospitals and other non-profit-making institutions. A few cars were delivered to churches. Many cars enroute to market were diverted back to the mines. In all cases the producing companies were compelled to pay the freight and other charges, and donate the coal. This action by the State Fuel Administrator had a tremendous moral effect upon the producers, and strengthened the arms of the Federal Inspectors at the mines, because publicity was given each case.

Many bituminous as well as anthracite operations have been closed because of the inferior coal shipped from them.

It is the observation of the Fuel Administration that steam sizes of anthracite containing 40 per cent of impurities are so inefficient in generating steam that the cost of such fuel is commercially prohibitory.

Allowable Limits for Impurities

Steam size of anthracite containing not more than 20 per cent aggregate impurities enable firemen to maintain maximum steam under the most difficult conditions. When the amount of impurities exceeds 20 per cent, there is at once a noticeably increased amount of fuel required to maintain normal steam pressure. In addition to this, there is an increase of 10 per cent in the cost of fuel when the percentage of impurities is increased from 20 to 25 per cent, and a further increased cost in the removal of ashes.

However, expert firemen obtain fairly good results with anthracite steam sizes containing as high as 30 per cent of slate and bone, but the fuel costs show an increase of 25 to 37 per cent above the cost of the same size fuel containing only 15 per cent of impurities.

Any steam anthracite containing more than 30 per cent of slate or bone is too expensive for the manufacturer to purchase today, according to our observation. All steam coal containing more than 20 per cent of impurities is condemned when it comes under the observation of the Fuel Administration. This is so even when it is found at destination points in Pennsylvania.

Impurities in Domestic Sizes of Anthracite

The effect of increase in impurities in domestic sizes of anthracite is much more marked than in steam sizes. The domestic sizes include pea, nut, stove, egg and broken coal.

Excellent results are obtained with pea coal containing 8 to 10 per cent of slate and the same amount of bone. That is a total of 16 lb. of impurities in 100 lb. of coal.

When the amount is 11 to 12½ per cent of slate, satisfactory results are obtained but ashes must be removed at more frequent intervals, and more attention given to the fire. At the same time, there is an increase of at least 5 to 8 per cent in the cost of fuel. This applies equally to this size of coal in use of low-pressure and high-pressure service.

Pea coal containing 20 per cent of slate is worthless for low-pressure boilers. In high-pressure practice, fairly good service can be obtained, but ashes must be removed at more frequent intervals and more attention be given to the fire. At the same time, there is an increase of at least 5 to 8 per cent in the cost of fuel.

In high-pressure practice, fairly good service can be obtained with 25 per cent of slate, but the cost of such fuel is virtually prohibitory. The larger the size of anthracite, the lower must be the percentage of impurities to obtain maximum service. No shipments of pea coal with more than 12 per cent of slate are permissible.

Chestnut gives best results when impurities do not exceed 5 per cent of slate and an equal percentage of bone (bone contains 50 per cent of carbon). Any increase above this figure is marked by inferior service. At 15 per cent fires must be carefully attended, or it will be necessary to relight them twice within 24 hours. Chestnut coal containing 20 per cent of slate is so inferior that any price for such fuel is exorbitant. All nut coal containing 7 per cent of slate is condemned by the Fuel Administration.

Stove coal containing 5 per cent of slate and 6 per cent of bone gives maximum service. At 6 per cent of slate and 7 per cent of bone, the result is increase of 8 per cent in fuel costs. This size coal containing 8 per cent of slate and 9 per cent of bone shows the maximum possible amount of impurities that can be used by domestic consumers, discounting the high cost of such fuel. Any percentage above this renders the fuel worthless.

Egg coal should not be used when the amount of slate is more than 4 per cent and 5 per cent of bone. This size of coal is difficult to burn unless it is virtually free from slate. Our standard permits 2 per cent of slate and the same of bone, and because of the size of this coal (it is the size of an average fist) the slate can be readily removed by the consumer. It is much better to do so than to obtain inferior results by shoveling the dirty coal into the furnace. It may be stated that the amount of slate allowed in this coal is only equal to one piece of slate in 100 lb., and two pieces of bone in the same weight.

Broken anthracite must be virtually free from slate or bone. Even in foundry practice, as well as domestic service, it is necessary to remove all slate from this coal before it can be

use. It can be readily perceived that this is imperative when the present schedule only allows 1 per cent slate and 2 per cent bone. This is less than the weight of a piece of bone or [illegible] size of fuel. During January many cars of broken anthracite were shipped from the mines into Philadelphia containing from 12 to 25 per cent of slate.

Imperative Need of Schedules for Limiting Impurities

There is a serious lack of authoritative data on the subject of schedules for impurities. It can be stated without question that bituminous containing more than 2 per cent of sulphur should not be used for locomotive purposes. Two and one-half per cent is the maximum that most standard railroads accept. More than 8 per cent of slate and other impurities makes the coal dear at any price. It is expected that rulings standardizing the quality of bituminous will be issued at an early date.

The essential need of authoritative data on the subject of impurities is emphasized by the attitude of some producers. Last Monday, the president of one of the largest anthracite-producing companies urged that the percentage of impurities in anthracite be increased 2 per cent above the existing standard.

When told that this will result in delivering annually to consumers, at least 1,500,000 additional tons of slate and dirt, at the highest prices ever obtained in the markets, one will readily agree that it is imperative that incontrovertible data should be at hand to sustain and make permanent the present standards governing anthracite deliveries.

To haul the proposed 2 per cent increased allowance of impurities would require about 40,000 railroad cars for a period extending from two to ten weeks, in 50 trains of 80 cars, each pulled by an equal number of locomotives, employing the necessary train crews.

The benefit of delivering one and a half million tons of slate and dirt would result in adding to the profits of producers to the extent of at least six million dollars!

The plea for this proposed allowance was based entirely upon the decreasing labor supply and the increasing needs for anthracite, but, as shown, to permit additional impurities would really increase the volume of fuel production but decrease the value of fuel delivered to consumption points. The Fuel Administration for Pennsylvania is giving serious consideration to some other method of increasing production without increasing the amount of impurities permitted in coal.

Any honest suggestion for increasing anthracite production by lowering the standard of preparation should be accompanied with an offer to reduce the market price in exact ratio to the decreased fuel value of the product.

What the Society Can Do

At this point it may be well to offer the suggestion that this Society take up the task of obtaining data on the commercial cost of impurities of fuel. Recommendations should then be formulated by this Society to the Fuel Administration, that may crystallize into legislative enactment that will make it a crime for unscrupulous producers to unload on consumers inferior product, in much the same way as manufacturers of food are prohibited from delivering to our tables product unfit for human consumption.

The mining and transportation of coal requires a vast army of workers. The quality affects every person in this great country. Is it not a question worthy of the most serious consideration that men of science can give it?

To this end, the writer is authorized to say that William Potter, Federal Fuel Administrator for Pennsylvania, pledges himself and his Administration to aid any measure undertaken to insure to consumers, industrial and domestic, reasonably clean coal as a permanent institution in the United States.

Because the anthracite production is confined to Pennsylvania, the responsibility for overseeing the quality of production rests largely on the shoulders of State Administrator Potter. And it is his task to see that the vast tonnage, reaching almost to 80 million tons, from the Pennsylvania mines shall be of a quality that will enable our manufacturers to produce the essential commodities of life with a minimum amount of waste, at the prices fixed by the Government.

The Administrator invites the patriotic support of this Society in his task of keeping the quality of coal delivered to our hearthstones at a high standard, so that the home fires in the United States may be kept burning brightly while we wait the return of the "boys" who have crossed the sea to battle with the Hun that man may work out his destiny free from the shackles of despotism.

THE FUEL-OIL SITUATION

By ALFRED C. BEDFORD[1]

The opportunity presented to me as Chairman of the National Petroleum War Service Committee to appear before you is one which I welcome and appreciate most heartily. But if you have been looking to the Petroleum Committee for an easy and quick solution of your fuel problems by the proffer of all the fuel oil you want to take the place of coal and other fuels, I am afraid I am due to disappoint you. I am here rather to plead for special economy in the use of fuel oil and for its use only where, from the nature of the work, you cannot properly use coal.

Do not think me an alarmist. I am not trying to warn you of any petroleum or fuel oil famine. But we are all one in our wish to help win the war, and, with that end in view, we want to adjust our available resources and supplies as effectively as we possibly can to the needs of the war.

What are these needs in regard to fuel oil? First and foremost is the Navy, and in the Navy for the war purposes which we are now considering, I include oil-burning cargo ships and transports, as well as the battleships, destroyers and submarine chasers.

Fuel oil is hardly less important for our ocean-going steamships, where one of its great values lies in the saving of space and weight, making possible the carrying of much larger cargoes than where room otherwise is given up to bulky coal supplies.

Our shipyards are rapidly reaching the point where large numbers of vessels will be launched. Careful computation shows that three oil-burning ships of a given tonnage of, say, 6000 tons each, will yield the same efficiency as four ships burning coal of a like tonnage. The tremendous importance of this fact of efficiency is shown when one realizes that three hundred oil-burning ships will carry the same cargo as four hundred coal-burning ships of the same size.

Meantime, the needs of our Allies have to be met, and exports of fuel oil have been for many months, and may be expected still to continue, on an ascending scale. When you add to these the requirements of the essential war industries for tempering, annealing, and other processes, for which coal is less suitable, you will realize the tremendous volume of the demand which simply has to be met.

[1] President, Standard Oil Company.

In 1917 our consumption was in excess of our production and importations of crude oil from Mexico, and it is fair to assume an increased consumption in 1918. Our production does not at present measure up very well to these anticipated demands, but, realizing the situation, oil operators everywhere are keen to develop it with all possible dispatch.

While fully cognizant of the important needs of fuel oil as related to the manufacturing industries, the point must be emphasized that it is impossible to take oil for any one specific purpose without exerting a detrimental influence on some other branch of industry. A very large volume of oil is being used today in the manufacture of gas, and much gasoline is obtained from what would otherwise be fuel oil. The demands for gasoline, however, are such that I must again earnestly urge upon every consumer the imperative necessity of conservation. Indeed, it may become necessary to enact definite and drastic regulations to restrict its needless consumption.

The oil men have organized so as to render the most efficient service, first, in supplying the full needs of the Government and the Allies, and second, in taking care of the ordinary business condition of the country along the lines of priority as laid down by the Fuel Administration.

What then are the conditions governing the present supplies of fuel oil?

So far as the Atlantic Coast is concerned, transportation is at the root of all of our troubles. While hundreds of thousands of barrels of petroleum are available in Mexico, and thousands more might be shipped from the Gulf ports, there is no way of getting these supplies North in the quantities needed. There is a shortage of shipping and the Government has found it necessary to requisition a large percentage of all the tankers in service. The pipe lines are running to capacity, and railroad conditions make it impossible to obtain any material relief by the use of tank cars. We are therefore face to face then with the necessity of making the available supplies of fuel oil along the Atlantic Coast cover the present ever-increasing essential demands. Coal can be obtained. The output of coal can be increased. But the supplies of fuel oil here at present cannot.

The consequence is we must ask the factories here in the East to burn less fuel oil, or none at all where it is possible to burn coal without interfering with the efficiency of the processes involved. Particularly, fuel oil should not be used under steam boilers, either stationary or locomotive. For metallurgical work in small forges and in large forge furnaces, and those used for annealing, etc., oil has its legitimate and essential place, though even here I would urge all the economy possible. But the ordinary user of heat apparatus for the production of steam power will do well to consider coal as his best source of supply, and disregard for the time being the possible advantages of oil.

Considerable difficulties were experienced in many quarters last winter, owing to the limited oil storage provided by consumers and to the irregular running of tank cars. I would therefore urge oil users to plan at once to increase their storage capacity to at least 60 days' supply, and to see that this storage, when completed, is kept full.

1 What Are the Economic Effects of Impurities in Coal?

Incombustible in fuel has a detrimental effect upon furnace operation out of all proportion to the percentage of refuse contained. It has been claimed that when coal contains 40 per cent of refuse it becomes valueless as fuel. Recent conditions have afforded opportunities for interesting observations in this connection. What has been your experience?

W. S. Gould.[1] During the last two years, as prices have mounted higher, the quality of the fuel shipped to market has decreased until lately the lack of quality of the so-called coal available to the power plants of the country has become a decided menace not only to our economic development but to the safety of the nation. It is incumbent upon every one to become familiar with the dangers of the situation and to use whatever influence he may have to force an immediate change in this aspect of industrial activity.

It makes no difference how much our railroad equipment is increased, it makes no difference what prices are fixed by the Government for coal, nor how many rules and regulations are issued by the Fuel Administrator, so long as drastic and effective steps are not taken to insure the proper preparation of the coal mined and shipped.

Efficiency Loss from Ash

The Bureau of Mines estimated that the ash of coal mined in 1917 had increased 5 per cent for the whole country, and that this increase in the ash content meant a further loss of 7.5 per cent in the efficiency of the power plants. Some of the mining districts show a much higher increase in this one element in coal. However, taking the Bureau of Mines estimate, this means in figures of tonnage, that while we produced and shipped 544,000,000 tons of fuel in 1917, the tonnage was equal in effective power-producing qualities to only 476,000,000 tons of the 1916 quality. In other words, in 1917 we mined and shipped about 41,000,000 tons more of material than in 1916 to do 27,000,000 tons less work. Assuming that the work done by the 544,000,000 tons of poor coal was all we had to do, we mined and shipped some 70,000,000 tons simply to make up for the inferior quality. This is the real cause of our coal troubles.

Shipment of Weathered Coal

This, however, is not the whole story. While the increase in the ash content was fully equal to 5 per cent, the decrease in the heat was considerably greater than 5 per cent, this decrease being due to the fact that millions of tons of weathered coal were shipped—pillar and outcrop coal and refuse from mine dumps—all of which was considerably lower in heat in proportion to the ash content than would have been the case if the coal had been freshly mined from the seam. The Fuel Administration originally encouraged these "wagon mines," the number of which increased enormously, directly cutting down the available fuel.

Influence of Sulphur on Clinker

In addition to the well-established loss in efficiency and capacity of our power plants, due to the higher percentage of the ash impurity, we should not lose sight of the further loss in efficiency and capacity due to the increase in the sulphur

[1] President, Fuel Engineering Company of New York, New York. Assoc.Am.Soc.M.E.

content of coal. Sulphur in coal affects the economy of the stokers by forming clinkers, which hinder the proper distribution of air. This improper distribution may be excess or deficiency of air.

It has been found that while the drop in the combined efficiency of the boiler and furnace averaged about 0.5 per cent for each per cent of sulphur between 0.5 and 6 per cent, the general drop in boiler capacity is about 1.5 per cent for each per cent of sulphur. The increased amount of clinker, due to the higher sulphur percentages, is doubtless responsible for this drop in the capacity, reducing the rate of combustion and therefore capacity. This loss is in addition to the losses estimated for increase in the ash impurity and the relatively greater loss in heat due to weathered coal.

Before 1916 eastern coals that carried sulphur in excess of 3 per cent were not common. Since that time the cases of 5 and 6 per cent sulphur, and some almost incredibly high, have steadily increased, until during the last winter it has been quite the exception to find coals with less than 2 per cent.

Then there is the damage that sulphur causes to the tubes, plates and grates of the equipment—a damage that is usually difficult to measure, especially since it is generally unexpected by the plant engineer, or comes when he has no time to make exact calculations or cannot get information as to his coal.

Just two examples of the many cases that have come under our own observation may be given:

a A plant equipped with Model stokers had been using a certain coal which did not average high in sulphur—about 1.60 per cent, but of a character that often causes trouble under similar conditions. The plant had been running wild, with a low rate of efficiency, and there had been no special trouble with the grate bars, which had stood up for weeks. Better operating methods were inaugurated, and the grate bars began melting at an alarming rate, some in about a week. Ordinarily, the cause of this trouble would have been laid either to the operating methods, and therefore a necessary evil, or to the grate bars. We selected, through our Library of Coal Records, a coal of equal heating value but without the characteristics of the coal being used at the plant, and the trouble with the grates ceased.

b Another case was in a plant with flat grates, hand-fired, and running at a low rate of combustion. This plant had been using a coal which was excellent so far as ash and heat were concerned, but which averaged about 2 per cent sulphur. The boilers not being forced, there had been no appreciable damage from the sulphur in the coal. A new lot of coal arriving, showing about 3.50 per cent sulphur, but otherwise being about as usual, I suggested that, with their operating conditions, they would probably find little trouble from clinkering, incidentally remarking that the only probable damage would be to their equipment. The superintendent asked if that were not more or less imagination, so I suggested his making a simple test of the point. One boiler was carefully cleaned and practically new grates installed. It was arranged that the 3.50 per cent coal should be used exclusively under this boiler for one day, and then the fires pulled and an estimate made of any damage that could be observed. A few days later we received a letter from the superintendent stating that the test was run as directed, and that "after four hours the grates were entirely destroyed."

WALTER N. POLAKOV.[1] The value of coal as used for power production is chiefly determined by its steaming capacity. Generally, there are two reasons for the condemnation of steam coals:

a When the composition and peculiarities are unfit for *existing* equipment

b When impurities make it unfit for *any* equipment.

Coals that are unfit for existing equipment or requirements should not be purchased at all, as they may be used to advantage elsewhere. The opinions on the subject advanced by miners, dealers, purchasing agents and accountants should be submitted for final disposition to engineers who are guided by facts.

Coals with a high percentage of non-combustibles were used by the author last winter in both hand- and mechanically-stoked furnaces. For instance, a mixture of 1 part run of mine and 5 parts of anthracite screenings was observed to show never less than 60 per cent of boiler and furnace efficiency. This mixture contained:

Ice and water	15 per cent
Earthy matters	28 per cent
Oxygen	2 per cent
Total	45 per cent

RESULTS FROM IMPURITIES IN COAL

From a large number of observations with coals contaminated with non-combustible impurities that are thrown on the market by some dealers at the risk of the country's liberty and honor, several conclusions may be drawn:

a While the efficiency of steam generation with so-called war coals drops from 10 to 25 per cent, the improved boiler-room management based on task work with bonus invariably more than offsets this loss. (Fig. 1.)

b The steaming capacity of coal drops along a parabolic curve; i. e., with the increase of ash content the evaporation drops more rapidly in the beginning and more slowly when ash percentage is getting high. (Fig. 2.)

c From Fig. 2 it appears that the increase of ash content from 14 to 18 per cent reduces the evaporation per pound of coal from 9 lb. to 8 lb. of steam (11.1 per cent), whereas further drop of evaporation from 8 to 7 lb. per pound of coal (12.5 per cent) corresponds with the increase of ash content from 18 per cent to 28 per cent.

It should be noted that these data are obtained from a number of hand-fired plants using mixtures of hard and soft coal for a period of over 18 months. The means of recording the performances were in all cases most rigorous, specialists taking continuous checks on accuracy, firemen trained and methods of firing constantly adjusted to secure the best possible results. While the deviations of results with each kind of coal are sometimes large, due to difference in plant equipment and degree of training of firemen, the tendency of retarded drop of efficiency with higher percentage of ash remains noticeable throughout.

d While extra cost of haulage and extra expense for the labor of handling coal and furnace refuse are easily estimated, the more important, though less noticeable, loss is due to difficulties connected with the admission of the proper amount of air into the furnace. If this is judged by the rate of firing (lb. per hr.), excess of air is inevitable with coals high in ash. Similarly, if direction is given by draft indications, extra resistance of fuel bed is liable to mislead the fireman. Again, if adjustments are based on gas analyses, the improper velocity of gases

[1] Consulting Engineer, 31 Nassau St., New York. Mem. Am.Soc.M.E.

through the boiler may lower the efficiency of heating surface for the sake of high furnace efficiency, ultimately at the expense of combined efficiency. Also, losses are incurred by more frequent cleaning of fires.

e By far the greatest economic effect of impure coals is the misuse of rail and water facilities for transporting the harmful, or, at best, useless, ingredients. The National

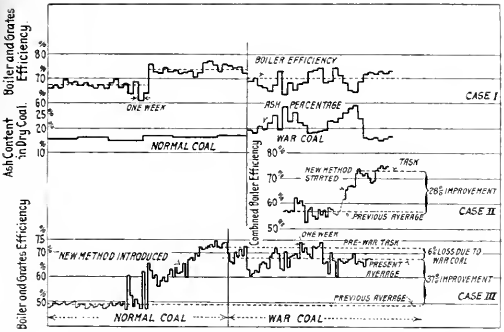

FIG. 1 EFFECT OF IMPURITIES IN COAL ON BOILER EFFICIENCY IN TYPICAL POWER PLANTS

Note: Task Work with Bonus more than offsets the harmful effect

Coal Association in a statement issued April 28, 1918, announces that "Interference with the war program is almost inevitable throughout the East, unless there is a readjustment soon of traffic over Eastern railroads." Decrease in production of coal because of car shortage is estimated by the same authority at about 20 per cent.

f Instead of thus harassing the Government in its task of operating railways and jeopardizing the country's pro-

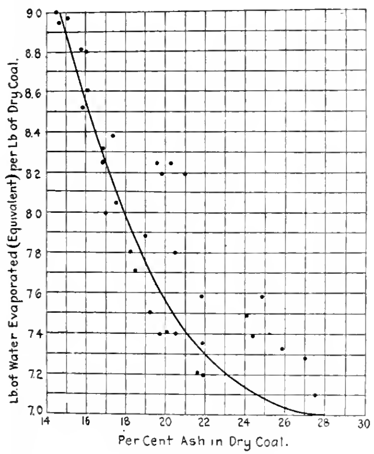

FIG. 2 RELATION BETWEEN ASH CONTENT AND EVAPORATION

duction at this grave moment, the coal producers could disprove the charge of disloyalty by more careful preparation of coal at the mines. Cleaner coal will, as we have seen, not only release large parts of the rolling stock engaged in transporting dirt and slate, but also reduce the tonnage required for steam generation.

g It is to be remembered, however, that half-measures toward preparation of cleaner coal at the mines will not go half way in ameliorating the present car shortage and furnace wastes. By reducing ash percentage from 28 to 21 per cent, only seven cars out of every 100 will be released, yet by removing also the other half of impurities from coal (*i. e.,* placing the quality of coal on pre-war standard) the need will be satisfied with 78 cars out of every 100 now tied up.

To sum up, the vicious economic effect of impurities in the war coal can be overcome as follows:

a A twenty per cent car shortage may be taken care of by releasing 22 per cent through reinstatement of previous quality of coal preparation.

b Further conservation of coal is possible by adopting more scientific methods of power generation and management of plants.

CARL J. FLETCHER.[1] During last winter much coal was wasted throughout Indiana due to the forced change in fuel. There are three very marked differences between the coal mined in Indiana and the coal mined in eastern Ohio, Pennsylvania and West Virginia: first, the amount and quality of the volatile matter; second, the liability to clinker; third, the form in which the impurities occur in the coal as delivered at the boiler room.

Regarding the volatile matter, the eastern coal is higher in hydrogen, making the volatile gases more easily combustible, also less in volume. The principal trouble in burning Indiana coal lies in lack of combustion space, which is necessary for the burning of very high-volatile coal, and a proper distance from the fuel bed to the comparatively cold boiler plates, which robs the furnace of heat and does not allow a sufficiently high temperature for the combustion of all the volatile matter.

Second, the clinkering of coal, when western coal has been substituted for eastern coal, is due primarily to the fact that there is more iron pyrites in Indiana coal. Iron pyrites can be successfully burned without objectionable clinkering under proper conditions. More draft is required to burn Indiana coal, both to keep the grates cool and to get a proper mixture of the volatile matter with oxygen. It often happens that in planning for a change to Indiana coal the grate surface is enlarged, reducing the available draft over the fire, when the proper procedure in this case would be to increase the force of draft.

Regarding the difference in the form of impurities in eastern and western coal, the impurities in Indiana coal appear mostly as shale, which cannot be burned; whereas, ash in the eastern coal is generally evenly distributed throughout the coal, and when eastern coal is burned it is a comparatively easy matter to free the fuel bed of ash. Shaking grates, such as are suitable for eastern coals, generally fail when applied to western coal. It does not do any particular harm to stir and mix some coals, while other fuel beds must not be disturbed. To burn Indiana coal it is necessary to have a type of grate with at least 50 per cent air space, and a grate which will crush the larger pieces of impurities and remove these impurities with a minimum disturbance of the burning fuel.

C. E. VAN BERGEN.[2] The value of coal producing 40 per cent ash depends, first, on the price of coal; second, on the expense of placing it on the grates; and third, upon the cost of removing the 40 per cent ash. We estimate that such a coal

[1] Fuel Engineer, Knox County Coal Operators' Association, Indianapolis, Ind.
[2] Vice-President and General Manager, Duluth (Minn.) Edison Electric Co.

will evaporate, under ordinary conditions, 3 lb. of water.

Our records show, that the coal we used from November 1, 1916, to March 1, 1917, evaporated 7.62 lb. water per lb. coal and contained 10 per cent ash. From November 1, 1917, to March 1, 1918, our coal contained 17 per cent ash and evaporated 6.69 lb. water per lb. coal. An increase of 7 per cent in ash content resulted in a loss in evaporation of 12.2 per cent.

W. L. Abbott.[1] In experiments made with a chain-grate stoker, using Illinois coal mixed with various percentages of ash, the capacity and efficiency of the unit dropped gradually with an increase of ash up to 35 per cent, after which they declined rapidly to zero efficiency and capacity with a fuel containing 40 per cent ash. The fuel would still burn, but the boiler would not generate steam. The fuel used in the test was made by mixing various amounts of ashes with a clean pea coal, the ash content of which was about 8 per cent. Thus, in the final test, the coal containing 8 per cent of ash was mixed with an additional 32 per cent of impurities. A different furnace or stoker might have given a somewhat different result, but it is questionable if any other form of stoker would have handled a fire containing that great amount of readily fusible ash.

Results obtained from this series of tests, which were made by mixing ash with the coal, correspond with results obtained by the Bureau of Mines in tests made in St. Louis using coals with an inherent ash content ranging up to 25 per cent, above which point the Bureau's tests did not go.

In a gas producer a fuel mixture of the kind first described would, no doubt, have given some useful results. A blast furnace always operates with a fuel mixture containing more than 40 per cent of non-combustible. If a coal contained as much as 40 per cent ash, it would not be marketable, and might rather be called a bituminous shale. Marketed coal contains between 2 per cent and 15 per cent ash, as extremes, but is usually below 10 per cent. If the fuel mixture carries more, it is due to impurities which are associated with the coal; for example, a coal seam analyzing 10 per cent in a seam sample may produce mine run containing 15 per cent ash.

With increasing ash content there is a decreasing boiler efficiency and an increasing cost of the steam produced, and while coal containing nearly 40 per cent of ash may produce some steam, it is rare indeed that it is economical to use coal containing as high as 20 per cent ash.

H. Kreisinger.[2] In the outline of this topic is a statement that when a fuel contains 40 per cent refuse the fuel becomes valueless. This statement cannot be applied generally as there are places where such fuel has economic value. In power plants located near the mines, washery refuse containing less than 50 per cent combustible can be used profitably, especially if the furnaces are designed for burning such fuel.

Some time ago the Bureau of Mines made a boiler test with washery refuse containing 41.8 per cent of ash, 10.8 per cent of moisture, 47.4 per cent of combustible. The test was made under a 200-hp. Heine boiler set up with ordinary hand-fired furnace with plain grate. About 75 per cent of the rated capacity of the boiler was developed with average over-all efficiency of 47.5 per cent. Of the 47.4 per cent of combustible in the fuel, 8.6 went with the ashes into the ashpit, an equivalent of 22.5 was absorbed by the boiler, an equivalent of 10.4 went up the stack with the gases, and the equivalent of 5.9 was lost by radiation, incomplete combustion, and moisture in fuel. The largest loss was up the stack due to large excess of air. The draft was 0.92 in. at the base of the stack, 0.06 in. in furnace, and 0.75 in. pressure in ashpit. The average thickness of fuel bed was 16 in. The fire was cleaned every hour. On account of the necessity of this frequent cleaning the average capacity fell below the rating of the boiler, although between the cleanings of fire the capacity developed was above the rating. It was also due to this frequent cleaning that the stack losses were high.

The essential requirement for the economical burning of high ash fuels is a continuous and automatic removal of ash from the furnace, so that the operation of the boiler need not be interfered with by frequent cleaning of fires.

A few weeks ago the Bureau of Mines received a letter from the president of a mining company, who was planning a furnace for burning washery refuse running about 40 per cent of combustible. This is a step in the right direction; the only place where it may be profitable to burn washery refuse or any other low-grade fuel is right at the source of such fuel so that the freight on the high ash is eliminated from the cost of the fuel. It would be wrong under the present railroad-car shortage to ship high-ash coal from the mines. At present the production of the coal mines is about 30 per cent below normal, and most of the deficiency (about 26 per cent) is caused by shortage of railroad cars. Therefore, the available railroad cars should be used only for hauling clean coal.

B. S. Murphy.[1] The following notes are based on data from the Hudson & Manhattan R. R. Co., and especially from its Jersey City power station, which is an anthracite-burning steam-electric plant for an electric railway

The boiler equipment consists of nine 900-hp. Babcock & Wilcox boilers, eight hand-fired and one equipped with a Coxe mechanical stoker.

The fuel is anthracite of the small sizes. Our practice is to use Nos. 3 and 4 buckwheat mixed with bituminous and some No. 1 buckwheat, this latter with no soft coal added. All fuel, 115,000 tons of anthracite in 1917, came from the same contractor, and approximately all of it originated from the same collieries, so that the combustible portion of the coal

TABLE 1 CALORIFIC VALUE OF COAL AS FIRED, B.T.U.

Year	Minimum	Average	Maximum
1911	11,230	11,523	11,750
1912	11,050	11,428	11,650
1913	11,450	11,741	12,000
1914	11,550	11,912	12,050
1915	11,550	11,712	11,900
1916	11,150	11,563	11,850
1917	10,850	11,170	11,350
1918 (3 mos.)	10,750	10,900	11,150

should be relatively the same. On the graph, Fig. 3, I have plotted the calorific value of the fuel by months in 1916 and 1917 with the first three months of 1918. In Table 1 are given the yearly averages and the maximum and minimum months during the year.

An ash analysis gives relative values for the ash content of coal, but the true test is the proportionate amount of furnace refuse as compared with coal fired. Such a figure, taking into account the unconsumed carbon as well as the ash and other incombustibles for the amount and kind of ash, has a great

[1] Chief Engineer, Commonwealth Edison Co., Chicago. Mem. Am. Soc. M.E.

[2] Engineer, United States Bureau of Mines, Pittsburgh, Pa. Mem. Am. Soc. M.E.

[1] Superintendent of Power, Hudson & Manhattan Railroad Company, Jersey City, N. J. Mem. Am.Soc.M.E.

bearing on the fuel in the ash, especially for hand firing. The average values of this for 1917 and 1918 are shown in Fig. 4.

From the foregoing it is evident that there has been a marked deterioration in our coal. The resultant economic effect I have shown in Fig. 4, which gives the average relation between the calorific value of the fuel as fired and the relative overall plant economy. This has been plotted by the relative percentages, that is, assuming that the best coal we could

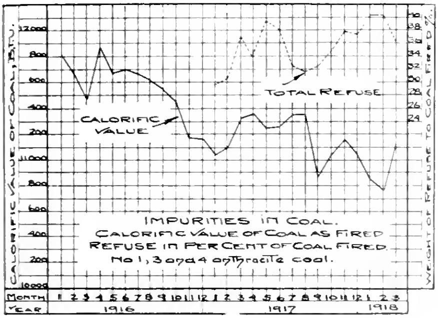

FIG. 3 SHOWING FLUCTUATION IN HEATING VALUE AND REFUSE CONTENT

expect would give a plant economy of 100 per cent, then a coal of 10,500 B.t.u. will give but 53 per cent of this value, and extending the curve it becomes zero at about 9,000 B.t.u., or the effective range is from 9,000 to 12,000 B.t.u. In figuring the effect of a decrease in calorific value of the coal under consideration, this range should be used and not the whole range down to zero B.t.u.

EFFECT OF HIGH ASH

Some of the poorer coals have ash by analysis as high as 24.45 per cent, with 10,294 B.t.u. calorific value of wet coal, while the better ones have only 9 per cent with 12,000 B.t.u., or a 15 per cent difference. On the calorific-value graph this is plotted, and though the curve is not extremely accurate, it would indicate that the limit for our coal was reached with about 30 per cent ash, this having a greater effect on the mechanical manipulation of the fires than on the lack of heat value.

The above is based on hand-fired operation where the impurities content and kind of ash has a much greater influence than with stokers. The railroad load having marked morning and evening peaks is subjected to this much more than a plant with an average all-day load. The presence of impurities builds up the fires so rapidly that at times it is difficult to get through the service period without cleaning and necessitates the carrying of high ashpit pressures, at times 7 in. water gage, to burn the fires. Another noticeable feature that we have found with the No. 1 buckwheat is the formation of a light, puffy ash that builds up the fires so rapidly that they last only about three-quarters of an hour between cleanings, while an analysis of this same fuel shows but 16 to 17 per cent (gravimetrically) of ash, or a normal ash content, again showing that too much dependence cannot be placed on laboratory analysis for the effect on the fuel of the ash. As a rule, with anthracite the ash does not fuse into large, hard clinkers found with many kinds of bituminous coals; but even this has been noticed during the past winter, some of the clinkers being so large and so hard as to necessitate their removal through the fire doors instead of through the ash hopper.

Unconsumed Carbon in Refuse. In our station it is necessary to force the boilers during the service hours to 140 to 150 per cent rating. To do this with good firemen and good coal is not difficult, but when the impurities increase and the quality of men falls off it is extremely hard, one affecting the other. It is necessary with the good grades of No. 3 buckwheat to level fires about every eight minutes, and with the high impurities and uneven spreading it should be done every three or four minutes. This is heavy, hot work; it is much easier to "bail" in coal, and the result is that the fire continues to build up because the ash and coked coal are covered with green coal until the fire becomes so heavy that it is impossible to get air through it. Cleaning then wastes a large amount of unconsumed carbon to the ashpit. The magnitude of this loss is shown in Table 2. With good fuel and well-trained, willing firemen this has been brought down to less than 20 per cent.

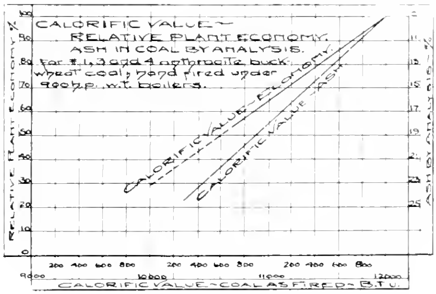

FIG. 4 INFLUENCE OF ASH CONTENT AND HEATING VALUE OF COAL ON PLANT ECONOMY

Summary. Summing up for the conditions as outlined for hand-fired boilers with the present grade of firemen available using Nos. 3 and 4 buckwheat coal with a relatively small percentage of bituminous, we find the following:

Calorific value, low limit, 10,200 B.t.u.; ash, high limit, 30 per cent, depending upon the behavior of the impurities.

Effect on Plant Economy: An increase in consumption per kw-hr. of 53 per cent from 12,000 B.t.u. to 10,500 B.t.u. coal. More coal is consumed, more coal is handled to the bunkers and to the fires and more refuse removed, increasing the unit cost of power.

Effect on Personnel: Much hard work for firemen with the result that the better men leave for easier work, poorer men hired who use proportionately more coal and consequently make more work for themselves.

Capacity: The capacity of a plant is limited by the small evaporation per pound of coal and the much shorter periods between cleanings.

Remedy. If the amount of impurities and the correspondingly low calorific value cannot be remedied at the mines, where some of this should be eliminated, then the remedy at the fire room is the increasing of the bituminous-coal content in the mixture, the introduction of mechanical stokers and the training of firemen, if the men can be induced to stay long enough to be trained.

R. H. KUSS. Close observation supports the following views:

It is feasible to arrive at accurate conclusions on the subject of comparative performances in well-conducted plants only, since ash-variation effect is obscured when accompanied by operation slovenliness.

The well conducted plant employs its available draft intensity to advantage, meaning by this that the unit rate of capacity tends to be such as to demand strict attention to tightness of settings, baffle repairs, cleanliness, etc., resulting in a comparatively high rate of combustion where slovenly methods are not permissible.

A marked increase of ash content in the coal compels a reduction in the usual unit capacity rate due to greater grate-refuse resistance.

A corollary effect is to carry thinner active fuel beds, attended with unevenness of air distribution through like grate zones in order partially to overcome the disadvantages of lower capacity rates.

With a surplus of draft the ill effects of ash increases can readily be overcome, though plant practice as to firing methods must be modified to suit.

Where extra draft intensity is employed to overcome increased fuel-bed resistance due to extra ash, the necessity for setting tightness is increased.

The usual condition is that available draft intensity is deficient, and there is no choice but to operate at lower capacities, thereby causing plant standby fuel losses due to radiation, banking, blow-downs, soot blowing, combustible in the refuse, etc., to increase.

The writer customarily attributes one-half of one per cent as a justifiable decrease in efficiency for every one per cent increase in ash content, but believes this to be a fair figure only when the increase does not exceed ten per cent of the total in ash content as revealed by a chemical analysis of the coal as fired.

A. S. VINCENT.[2] The building of which I have charge is the largest apartment house in the world, occupies a whole block, has 175 families and is thoroughly equipped with a high-class isolated plant. Our horsepower-hour outputs for 1916 and 1917 were almost identical, and yet for 1917 consumed nearly 1000 tons more than we did in 1916, due only to the inferior grade of coal. In other words, the coal consumption in 1916 was about 7000 tons and in 1917 it was 8000 tons. This plant is equipped with everything an engineer could desire to enable him to keep plant records.

Our cost per boiler horsepower-hour in 1916, including all overhead charges, was $0.0114 and for 1917 was $0.017, due almost entirely to the excess coal used and at a cost of more than double the 1916 cost.

ALBERT A. CARY.[3] In an investigation made in a number of the largest power houses in the East during the latter part of 1917 in the interest of fuel conservation and its bearing upon the transportation problem, I found that over 30 per cent of all transportation facilities carrying bituminous coal were burdened with unnecessary impurities. By unnecessary impurities I mean those above the normal ash which had been carried in the coal when the power houses were obtaining their coal under specifications defining the minimum B.t.u. per pound of coal and maximum ash content acceptable.

A. J. GERMAN[1] (Oral). Our experience with the impurities in coal has been interesting. We at first had trouble unloading the coal in that the foreign matter in the coal broke the crusher gears. More trouble is given when the coal comes into the automatic stokers. Then there is the further damage done to the furnace side walls and to the bridge walls. When about to unload coal we try to pick out the slate and rock on top of the car. We picked up pieces last winter as large as 4 ft. in length, 2 ft. in width and 5 in. in thickness. We picked out 9000 lb. of such material from three forty-five-ton carloads.

We use coal crushers with one set of rolls with bearings having spiral springs so that the rollers may give way and pass a too solid piece of material, such as rock and slate. Nevertheless, we had considerable trouble with the breaking of the crusher. To avoid this we put in relays with an automatic overload release. This stopped the trouble, which may be considered to have been rather severe inasmuch as we broke six gears, three shafts and a number of bearings last winter. We use a chain-grate stoker, and we have found that the great increase in the amount of dust in the coal allows a considerable quantity of the screenings to fall through the grate. We catch these in a hopper placed under the front of the stoker.

R. J. S. PIGOTT[2] (Oral). In connection with the points brought up with regard to the effect of the increase of non-combustible material in coal, it is quite true that both the efficiency and capacity are seriously affected in hand-fired plants. It is found, too, that with the proper operation only capacity is seriously affected. In two well-operated plants, the efficiency of the boiler room has not been seriously affected by bad coal; but the capacity and maintenance of the equipment are affected. The increase in ash cuts down the heat value, or B.t.u., that can be developed per sq. ft. of grate per hour. Of course, the increase of ash simply cuts down the B.t.u. that one can get into the furnace per sq. ft. of grate. The trouble is that many plants, due to the large increase in ash, have to run close to their safe margin of capacity, and, as it is difficult, at this time, to get additional apparatus, the trouble is a serious one. Therefore it is the hand-fired plant that suffers most seriously from this condition, and it is that plant to which the Fuel Administration will have to give the greatest amount of help.

P. W. THOMAS.[3] The incombustible portion of the coal limits the actual amount of heat contained in one pound of coal: its nature determines the percentage of contained heat which will be available for initial furnace temperature, and the components of ash have more bearing upon stoker design and furnace design than those of the combustible portion of the coal.

[1] Consulting Engineer, Chicago, Ill. Mem. Am.Soc.M.E.

[2] Superintendent and Mechanical Engineer, The Belnord Apartments, New York City. Assoc. Am.Soc.M.E.

[3] Consulting Engineer, New York. Mem.Am.Soc.M.E.

[1] Waterbury, Conn.

[2] Consulting Engineer, Bridgeport Brass Works, Bridgeport, Conn. Assoc. Mem.Am.Soc.M.E.

[3] Fuel Engineer, Central Coal & Coke Co., Kansas City, Mo.

The following functions of the stoker are affected by the quantity and nature of the ash:

a Weight of coal fed per unit of heating service per hour
b The character of the fuel bed
c The coking time of the combustible coal
d The nature of the coke residue
e The proper diffusion of air admitted
f The actual mechanical performance of both moving- and stationary-stoker metal.

The design of the furnace is greatly affected by the nature of the ash and should be such as to avoid the following defects:

1 Impregnation of firebrick with slag formation
2 The building up of the smaller particles of fusible ash in the furnace, by which the throat is restricted.

Another item of consideration with respect to the ash, especially in horizontally baffled boilers, is that the velocity of the gases through the first pass must either be slow enough to deposit the ash particles in the combustion chamber or sufficiently strong to carry them toward the last pass to a lower temperature. If deposited in the first pass in a high temperature, they will build on the tubes and bottle the furnace.

To our minds, then, the stoker should be selected after an investigation of the ash in the coal to be used. A typical analysis of fluxing ash is given below:

Silica as oxide	43.50
Alumina	17.10
Ferric oxide	28.10
Calcium oxide	5.30
MgO	0.75
Sulphur (sulphide occluded in CaO)	2.75
Carbon dioxide	trace
Carbon unburned	1.90
Alkali	trace
Moisture	trace
	99.40

Probable fluxing temperature, 2138 deg. fahr.

(Cosgrove states that silica melts at 3227 deg. fahr. A silicate formed by the combination of FeO and SiO fuses at 2318 deg. fahr., and if part of this silica is replaced by 16 per cent CaO, the resulting iron-lime silicate will fuse at 2138 deg. fahr. The above ash, if considered from the standpoint of these three metals, contains 57 per cent silica, 37 per cent iron, 16 per cent calcium.)

If the slag is allowed to accumulate in any receptacle such as a dump grate or ash pocket, its peculiar viscous nature will invariably cause trouble. Sooner or later the mechanism of the ash dump will clog, with a resultant shutdown for repairs to both ash pocket and grate.

If any of these coals is carried on a thick fire, an inversion or disturbance of the fuel bed will precipitate an ash run in the fuel bed proper. The slag is so heavy that I have known it to settle down into the tuyere boxes against a pressure of 5 in. of water, and within two hours close the entire air supply of the furnace.

Once the air is shut off, the condition becomes aggravated in the following manner: The pyrite FeS_2, instead of oxidizing to the relatively harmless ferrous oxide, reduces to ferrous sulphide, FeS, which has the same fluxing temperature as the ferrous lime silicate, 2138 deg. fahr., but when the FeS melts, it runs over the metal of the furnace and destroys it. Troughs and dead plates are warped and wasted. A run of molten iron sulphide through a grate of any type will in a few hours carry enough metal from the stoker to the ashpit to shut the boiler down.

2 To What Extent Is Fuel Oil Likely to be Used as a Substitute for Coal?

Information is desired as to present use, advantage found, probable available supply, etc.

Ernest H. Peabody.[1] At the end of 1914, the total aggregate world output of oil since 1857 had reached the enormous total of about 5,500,000,000 bbl. (of 42 U. S. gal. each), of which the United States had produced about 60 per cent. By the end of 1916 this had risen to 6,478,944,229 bbl. In 1916, it is estimated, there were produced 460,639,407 bbl., of which the United States produced 300,767,158 bbl., or 65 per cent.

The data in Table 3 are from the preliminary report of the U. S. Geological Survey, and show that in the year 1917 the production in the United States had increased some 14 per cent over 1916, reaching the record-breaking total of nearly 342 million barrels.

Forty Per Cent of Oil Available for Fuel Purposes

At least 40 per cent of all the crude oil produced will be available for fuel purposes. Notwithstanding the great amount required for war purposes, particularly in the Navy and the rapidly increasing merchant marine, it is well worth asking whether or not oil fuel can be obtained for steam production on shore.

No definite statement can be made as to the availability of oil in any particular locality, especially under the existing conditions. At all times, in fact, this is purely a local question. In California, until recently our largest oil-producing state, and where no coal of importance is mined, oil will doubtless continue to displace coal. In Pennsylvania, on the other hand, there are great coal deposits, while the oil produced is of a variety exceedingly valuable for refining purposes, so that coal as fuel holds decided superiority over oil except for special uses. In other portions of the country the balance may fall either way—as the production and the demand vary and as the transportation problem may determine. It would

TABLE 3 FUEL-OIL PRODUCTION BY DISTRICTS IN 1916 AND 1917

Field	1916	1917
	Barrels	Barrels
Appalachian	23,009,455	24,600,000
Lima—Indiana	3,905,003	3,500,000
Illinois	17,714,235	15,900,000
Oklahoma—Kansas	115,809,792	147,000,000
Central and Northern Texas	9,303,005	11,000,000
North Louisiana	11,821,642	8,700,000
Gulf Coast	21,768,096	24,900,000
Rocky Mountain	6,476,289	9,200,000
California	90,951,936	97,000,000
Other Fields	7,705	....
	300,767,158	341,800,000

[1] Consulting Engineer, Babcock & Wilcox Co., New York City.

seem as if the Middle West should be well supplied with oil, as Oklahoma now produces more than one-fifth of all the oil in the world. Oklahoma wrested the production laurels from California in 1915.

The Mexican production, while already very large (nearly forty million barrels in 1916), has been restricted on account of a deficient amount of tonnage to take the oil away. With adequate shipping facilities it is probable that the Mexican fields will constitute the natural source of oil-fuel supply for New England and the Atlantic states. There is one well alone in Mexico, the Cerro Azul, estimated to have flowed 263,000 bbl. a day, and it is interesting to speculate on what these fields may finally produce.

All indications point to the probability that there are enormous quantities of oil yet hidden in the earth's crust to be one day brought forth by the prospector.

Care Required to Prevent Waste of Oil

A coal fire in the hands of a lazy or incompetent fireman may indeed fall far below the desired standards of excellence; but it can only reach a certain minimum level of efficiency, and then it will go out. Coal is, in fact, of such a nature that it will quietly stand a certain definite loss in economic results, and then it will quit.

With oil there is no limit to the possible wastefulness that may exist. Give it poor burners, improper furnace conditions or not enough draft, and it will smoke and sputter and drip oil and waste itself away, but never give up. Give it too much air, a hundred times too much, and the fire will burn, the oil will disappear, the flame will be bright, there will be no smoke; but the waste may be so great that the boiler will not make enough steam to run the feed pump, even with the best furnace and burner arrangement.

It is approximately true that 1 lb. of oil equals $1\frac{1}{2}$ lb. of coal in actual steam-making results. Roughly, this is equivalent to saying that 200 U. S. gal. of oil equals one ton (2240 lb.) of coal, or one ton of coal equals about $4\frac{1}{2}$ bbl. of oil.

A very handy rule, but like the rest only approximately correct, is this:

> When the price of coal in dollars per ton (2240 lb.) is double the price of oil in cents per U. S. gallon, the cost of fuel for producing a certain boiler capacity will be the same for both fuels. Thus two-cent oil equals \$4 coal, or four-cent oil equals \$8 coal.

This rule takes into consideration the probable increased boiler efficiency obtainable with oil, but makes certain assumptions concerning the heat values of the two fuels and the weight of the oil per gallon which, while generally representative, may or may not be correct in any specific instance.

Generally speaking, one oil burner will be required for, say, 350 to 400 boiler hp., and one oil fireman can attend to about ten burners.

Reliable tests with oil fuel have shown that the boiler efficiency (i.e., the percentage of heat units in the oil which is actually absorbed by the steam leaving the boiler) may be as high as 83 to 84 per cent, although 78 to 80 per cent may be considered as good work, or even 75 per cent, in regular operating conditions. With coal fuel, while reports have been published by some pseudo authorities showing over 80 per cent, the writer believes that such high results with coal can only be obtained with very large boiler units and the most efficient mechanical stokers. Certain it is that in hand-fired plants, 75 per cent is about the maximum, while 65 per cent may be considered very good average work.

The advantage possessed by oil in respect to increased efficiency is due primarily to the small amount of air required for complete combustion in excess of the theoretical amount. This may be reduced to 10 per cent with oil, while the best tests with coal, hand-fired, show about 50 per cent, and good every-day working conditions run as high as 80 or 100 per cent.

Maintenance Less with Oil than with Coal

Maintenance charges are decidedly less than with coal. It is true that higher furnace temperatures with oil as a rule require a better quality of firebrick, and danger may result to boiler heating surface with improper furnace arrangements and burners. These points are easily cared for.

The theory of burning oil is different and radically distinct from that controlling the burning of solid fuel. Pulverized coal of course in some respects closely approaches the character of burning oil, but coal fired by hand or by stokers remains substantially at rest during combustion, and the air is brought to it. In the case of oil, the fuel is moving and the air moves with it.

In varying the rate of combustion of coal, the amount and velocity of the air through the fuel bed is altered—the intensity of the draft is increased or decreased. In the case of oil, the amount of fuel itself and the rate at which it enters the furnace must be varied, and the amount of air entering with it must be increased or decreased to preserve the proper ratio.

The lighting of an oil fire is a simple process. The oil pump is started to give the necessary oil pressure at the burners. The draft is opened to provide sufficient air for combustion. A lighted torch is then placed directly under the burner tip, and the oil is then turned on. If the oil is at the proper temperature and the atomizer is working properly, the spray at once bursts into flame. The spray must never be started without first lighting the torch; i.e., no oil must be injected into a "dark furnace," for if it is, an explosive mixture may be formed in the furnace which will cause damage if ignited.

There is little or no difference in the action of compressed air and steam in atomizing oil as far as boiler work is concerned, and if the air is compressed to over 30 lb. per sq. in. there is no special difference in the design of the burner itself.

So far as the steam-boiler furnace is concerned, however, the prospective user of oil may forget the air atomizer, the one instance in which its use might be considered being that in which the saving of fresh water (consumed by the steam atomizer) is a matter of importance. And in this case a mechanical atomizer will probably do the work effectively, and will be preferred.

Selection of Type of Burner

As between the claims of the steam atomizer vs. the mechanical atomizer, the issue is not as clear cut. On board ship, except in the case of harbor vessels or those making port every day, the steam atomizer has given way to the mechanical atomizer, where the saving in fresh water for the boiler makes the use of the latter type practically imperative.

There is practically nothing to choose between the two types in operating results under equivalent conditions. The steam atomizer is, however, more flexible, i.e., the individual burner has a greater range in capacity; it costs less to install, notwithstanding that it requires two lines of pipe (oil and steam), whereas the mechanical uses only one, and that for the

oil. It is more readily applied to a coal-burning furnace, and conversely the furnace is more quickly converted back again to coal. It requires a lower oil pressure and not so high a temperature for viscous oils. It will also, in general, require less draft to operate. Furthermore, where special arrangements of burners are required, as in the case of the so-called "back-shot" burner (placed at the rear of the furnace), the steam atomizer is susceptible of a wide range in design which has been found useful.

Oil Pressure and Temperature

For steam (or air) atomizing burners, oil pressures of 25 to 50 lb. at the pumps are adequate, and under certain conditions even less pressures. Overhead tanks a few feet above the burners, feeding the oil by gravity, have been employed, but this is inadvisable on account of danger of fire, and pumps are usually employed. Mechanical burners require pressures of 50 to 250 lb. at the burner tip, 200 lb. being a favorite pressure for the designer. The wide range of pressure is useful in adjusting the burner capacity. A steady oil pressure is a necessity for oil burners, a vital necessity for mechanical burners. Therefore large air chambers on the oil line are needed if the usual duplex reciprocating pump is used. Rotary pumps are being introduced in the Navy, and recently the screw pump has come into vogue. These pumps give a steady pressure of oil with little or no air cushioning, and the screw pump, particularly, seems to possess great possibilities for this work.

The matter of heating the oil is rather of a mechanical nature as its importance bears on the viscosity of the oil rather than on any thermal advantage. Steam atomizers will handle more viscous oil than the mechanical type, therefore steam heaters using exhaust steam from the pumps and capable of heating the oil to 100 deg. to 125 deg. fahr. are usually satisfactory. The mechanical burner requires that the viscosity of the oil be reduced to 8 to 10 deg. Engler to spray properly, and this means that the oil (according to its viscosity) must be heated to 120 deg. to 280 deg. fahr. The latter temperature is required for heavy viscous oils that are appearing on the market to a greater and greater extent. In a mechanical-burner installation it is evident that the oil heater is a most essential part of the equipment.

Importance of Air Regulation

To a certain extent the amount of air being delivered to an oil fire is indicated by the color of the flame, a very bright, intense white (so desirable with coal) usually indicating that too much air is being used, with a resulting loss in efficiency. Judging the fire by the flame, however, is only approximate; and it is better to resort to the simple device of diminishing the air supply until a light brown haze appears at the top of the chimney. This is preferable to a clear stack, as the latter gives no indication of excess air. The light haze is not at all objectionable but represents good conditions, provided—and this is a most important point—the smoke which produces the haze does not come from one or two burners only, while all the rest are working with oil. Complete combustion in the furnace (that is, combustion in which all the carbon is burned to CO_2 and no CO is present) will give an analysis with coal in which the CO_2 content, plus the free-oxygen content, will add up considerably higher in amount than an analysis of the products of similarly complete combustion of oil. The same percentage of CO_2 in the gas sample from coal indicates a much greater excess of air over that theoretically required than when oil is being burned. However, complete combustion of oil can be secured with a much lower amount of excess air than coal fuel; and it happens, therefore, that 14 per cent CO_2 in both cases represents the same satisfactory conditions in the furnace with both fuels.

The amount of air theoretically required for the complete combustion of fuel oil of course varies with the composition of the oil, but it may be considered that about 14 lb. or 18 cu. ft. at 60 deg. fahr. represents the average.

Boiler Furnace for Oil Fuel

In oil burning, "furnace volume" possesses a function similar to that of "grate area" in burning coal fuel. The rate of combustion of oil per cubic foot of furnace volume may be increased or decreased according to the intensity of the draft. A large furnace is necessary, therefore, if the draft is low, and the furnace can be made smaller if the draft is increased. This effect of furnace volume on the rate of oil combustion is often ignored or misunderstood; but it is of prime importance.

A high furnace temperature promotes the combustion of oil. Owing to the less quantity of excess air, oil furnaces are usually higher in temperature than those burning coal, so that good-quality firebrick with a fusing point at least 3000 deg. fahr. should be used. Notwithstanding the higher temperature, if the burners are set and operate properly so that no flame impinges on the wall and no hard carbon is deposited, the wear and tear should not be great.

W. N. Best.[1] The direct answer to this inquiry is: First, in whatever equipment oil as a fuel is found to be cheaper than coal; second, whenever by its use an increased output is secured; third, wherever a superior quality of metal is produced; fourth, to safeguard against shutdowns in power plants through shortage of other fuels; and fifth, to carry peak loads in power plants.

We will first consider oil in power plants. If the coal used has a calorific value of 14,000 B.t.u. per lb. (good bituminous coal) it requires 147 gal. of oil to represent a long ton of coal (2240 lb.), the oil having a calorific value of 19,000 B.t.u. and weighing 7.5 lb. per gal. With oil at 5 cents per gal., this would be equivalent to coal at \$7.35 per ton delivered in the coal bin. The larger the power plant, the more attractive is oil fuel, owing to the fact that one man can fire and water-tend twelve 300-hp. boilers. There are no ashes to handle and cart away. Of course the saving on all labor such as extra firemen and ash handling will vary in accordance with the number and size of boilers in the plant. I only mention this as a concrete illustration as to how an engineer can calculate the cost of the two fuels, so that anyone can definitely determine if oil is attractive or not. The data used has been compiled from hundreds of tests.

In the eastern part of the United States oil as a fuel is rarely found to be as cheap as coal when used exclusively as a fuel in boilers; but last winter's experiences fully demonstrate the necessity of having coal-fired power plants equipped with oil as an emergency fuel owing to the uncertainty of the coal supply, and also the delay in delivery occasioned by the shortage of coal cars. It is the writer's opinion that no power plant today is safe without apparatus for the use of oil as an emergency fuel. Also, oil may be used as an emergency fuel to carry peak loads on either hand-fired or stoker-fired boilers. The liquid-fuel-injecting apparatus may be placed in the side wall of the boiler, midway between the bridge wall and

[1] President, W. N. Best, Inc., New York, N. Y.

front-end setting or may be placed in the front-end setting and will not interfere with the fireman or stoker. A lever is used to operate the slide gate which admits the air to support combustion, independent of the air admitted through grates or stokers; thus, if it is desired to operate the oil burner at 15 per cent of its capacity, the gate is only opened sufficiently to admit just enough air for the perfect combustion of that amount of fuel in combination with the coal. It can be so operated that no superfluous air is admitted into the firebox by simply moving the lever to any position required. As soon as the supply of coal is entirely exhausted, the grates or stokers can be covered with cinders and oil burned exclusively. When a supply of coal is again secured, the cinders or ashes can be removed, the burner shut off and the air gate closed while only coal is again burned.

There are thousands of boilers in power plants and in gas works where to carry peak loads oil or tar is burned in combination with coal, breeze, etc. Also in power plants where bagasse is used as a fuel often oil is necessary to aid that fuel in obtaining the full rating of the boiler. Oil is an ideal fuel for this purpose, for by its use one can control and maintain the steam pressure as desired. It ordinarily requires three gallons of oil to each ton of bagasse burned.

I believe all marine boilers now burning coal should be equipped with oil as an emergency fuel, especially should this fuel be used in the time of war, for by its use in combination with coal the boilers can be operated at 200 per cent overload in a few minutes, thereby increasing the speed of the vessel to its maximum.

In forging plants oil should be used as fuel, for thereby the manufacturer secures the maximum output and a better quality of metal. In this practice 80 gal. of oil are equivalent to a ton of good coal.

In heat-treating furnaces (low temperatures) 72 gal. of oil are required to represent a ton of coal of the calorific value referred to. Since it is true that steel is only as valuable as it is heat-treated, oil is superior to coal, for by its use in modern furnaces any temperature required can be attained and maintained at the will of the operator, and an even distribution of heat obtained over the entire charging space of furnace.

In foundry practice oil is an incomparable fuel for core ovens, and in steel foundries for mold-drying ovens, etc.

In chemical plants where accuracy of temperatures is very important, especially in the manufacture of dyes, oil fuel is a necessity.

In welding flues 58 gal. of oil represent a ton of coal (all coal and oil referred to here have the same calorific value). This is due to the fact that it is necessary to coke a coal fire before welding two pieces of metal together, and in this process of coking the coal all the volatile gases are wasted.

In conclusion, I would say that owing to the superior qualities of oil, it belongs to that portion of the manufacturing world having forging and heat-treating shops, foundries melting various kinds of metals, and power plants for which an emergency fuel must be provided. I am confident that when the war is over the nation having control of the most oil wells will be the largest manufacturer in the world; and if Germany controls the oil fields of Roumania, and the Baku fields of Russia, our country's greatest competitor in the manufacturing world will be Germany, although we (the United States) now contribute 62 per cent of the world's production of crude oil. We must conserve this fuel and only use it where it can best serve the nation.

R. J. S. Pigott. One very important point militating against the substitution of fuel oil for coal, (even if a supply were obtainable, which it is not), is the relative price of fuel oil and coal per million B.t.u. In all but the most favored localities, coal is about one-half, or less, the cost of fuel oil per million B.t.u. For instance, at Bridgeport in 1915, coal was $4 a ton (14,250 B.t.u.) and oil 4 cents per gal. (19,000 B.t.u.); the relative cost was 12.65 cents per million B.t.u. for coal and 29 cents per million B.t.u. for oil. Any one contemplating the substitution of oil for coal would be faced with a doubled cost of steam production. The saving in labor due to elimination of coal- and ash-handling is insignificant. The difference in efficiency is now next to nothing, since the development of the underfeed stoker has put the coal-fired boiler practically on a par at all points with oil.

One very large source of waste, and an immense opportunity for saving, lies in our industrial heating processes. We have vast amounts of coal, oil and gas used in factory processes for heat-treating, annealing, pit fires, forge furnaces, etc., in nearly all of which cold work is introduced directly into an intensely hot chamber under direct flame, and no attempt whatsoever made to use the heat in the flue gases.

In connection with the writer's work at the Remington Company, we tested several types of oil-fired forge furnaces, as well as gas-fired brazing and other small-operation furnaces, finding the efficiency between 10 per cent and 15 per cent. In some cases, surface-combustion or semi-surface-combustion furnaces of our own design were substituted for Bunsen-flame types, cutting down gas to one-third, and in two cases, to one-fifth the former amounts. We should by all means employ preheating methods in our shop operations, making use of the familiar countercurrent principle so universally adopted in such heat-transfer apparatus as condensers, feed heaters and boilers. There is no question but that we could at least double the present poor efficiency of our usual primitive shop furnace.

Referring to the coal situation, the admirable work of Mr. Potter and Mr. Cole in Pennsylvania should have the hearty support of this Society, since it is a method of curing the cause, not the effect,—which eases the situation both from the coal burner's point of view and that of the transportation company. I therefore respectfully submit the following resolution:

Whereas, A large proportion of the shortage of fuel is due to the reduction of capacity and efficiency occasioned by the increase in non-combustible impurities in the coal as furnished from the mines, due chiefly to negligence on the part of the operators; and to the consequent increase in tonnage hauled for a given total heating-value.

Whereas, Mr. William Potter, Fuel Administrator of Pennsylvania, has taken effective steps to force the proper cleaning of coal by establishing inspection at the mines, standards of quality and punishment for infraction; be it

Resolved, That the members in attendance at the Spring Meeting of The American Society of Mechanical Engineers indorse and support the action of the above-mentioned Fuel Administrator of Pennsylvania.

C. H. Delany.[1] To engineers on the Pacific Coast where fuel oil has for many years been the only fuel available, the problem at present is, what fuel can be substituted for fuel oil, rather than to what extent can fuel oil be substituted for coal.

[1] Pacific Gas and Electric Co., San Francisco, Cal.

During the past two years the price of fuel oil on the Pacific Coast has almost trebled, and in the Northwest its use has practically ceased, other fuels being substituted for it.

In California, where there is practically no coal available, the use of fuel oil still continues, but as the consumption at present is considerably greater than the production, it is questionable how long its use can be continued without restrictions.

Oil-Fuel Shortage Will Grow More Acute

The situation will shortly grow worse on account of the immense quantities of fuel oil required for the Navy, especially for the large number of destroyers that are now being built. It seems, therefore, that unless there is a considerable increase in the production of fuel oil, it is useless to discuss the possibility of its being substituted for coal; however, there is always a possibility of new oil fields being opened up.

In Table 4 a comparison is given of fuel oil with coal of heating values varying from 10,000 to 15,000 B.t.u. per lb. The heating value of the oil is given as 18,500 B.t.u. per lb., which is a fair average value for California oil, the variations from this value being small. It is well known that with good grades of semi-bituminous coal better boiler efficiency can be obtained than with the low-grade western coals, and to make this comparison fairly correct for the different grades of coal, an efficiency of 60 per cent has been assumed for coal having 10,000 B.t.u. per lb., and 75 per cent for coal having 15,000 B.t.u. per lb., with intermediate values for the coals that lie between these extremes. As the heating value of coal is invariably given on the basis of dry coal, and as coal when purchased invariably contains a considerable proportion of moisture, it has been assumed that the coals considered in this comparison contain 6 per cent moisture. In the case of fuel oil the water content does not usually exceed 1 per cent and this value has, therefore, been used in the comparison.

TABLE 4 COMPARISON OF FUEL OIL WITH COAL OF VARIOUS HEATING VALUES

(Coal containing 6 per cent moisture)

	Coal						Oil
B.t.u. per lb. dry fuel	10,000	11,000	12,000	13,000	14,000	15,000	18,500
Boiler efficiency, per cent	60	63	66	69	72	75	78
Dry fuel per boiler hp., lb.	5.58	4.82	4.22	3.73	3.32	2.97	2.32
Fuel as fired per boiler hp., lb.	5.94	5.13	4.49	3.97	3.53	3.16	2.34
Coal equivalent to 1 bbl. oil (42 gal.), lb.	851	737	645	570	506	454	....
Price of 1 ton (2000 lb.) of coal equivalent to oil at $2 per bbl., dollars	4.70	5.43	6.20	7.03	7.92	8.82	
Price of 1 bbl. of oil equivalent to coal at $5 per ton, dollars	2.13	1.84	1.61	1.42	1.26	1.13	

The comparison given here considers only the actual value of the fuel itself. An oil-fired plant is considerably cheaper to build than a coal-fired plant, due to the lack of coal-handling apparatus, mechanical stokers, etc.; furthermore, the labor in the oil-fired plant is much less than in a coal-fired plant, consequently the actual comparison for any particular plant will be somewhat more favorable to oil than is shown in Table 4.

Fig. 5, which extends the information contained in the table to other prices of coal and oil, will serve as a rough guide for those who contemplate changing from one fuel to the other. The efficiency of 78 per cent for oil firing assumed in these calculations can be readily maintained in normal service provided proper attention is paid to the furnace design and the regulation of the fires.

Automatic Regulation of Fire

One of the greatest advantages of the use of oil as fuel is that it is possible to regulate the firing entirely automatically. It is well known that in the modern power plant the efficiency obtained depends very largely on the personal element in the fireroom. This personal element has been largely eliminated in the engine room by making automatic the regulation of modern prime movers. In the fireroom, however, it is customary to depend entirely on the judgment of the fireman to regulate the supply of air that will insure commercially perfect combustion and give the highest efficiency. By making this regulation automatic the method of operating the plant changes, for it is then only necessary to adjust the fires at the start, and if the automatic regulator is reliable, it will keep the fires in proper adjustment for all loads.

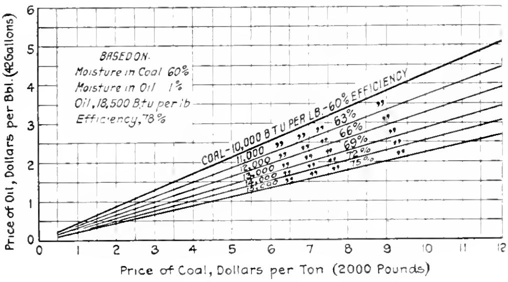

Fig. 5 Comparison of Fuel Oil with Coal of Various Heating Values

Automatic regulators are now on the market for oil burning which regulate the quantity of oil, the quantity of atomizing steam and the quantity of air required for combustion. While the main advantage of the automatic device is that it insures the boiler operating at maximum efficiency at all times, it also has the advantage of causing considerable saving in labor.

This advantage will be especially true in the case of small isolated plants where the firing is of poor quality and where the cost of labor is large in proportion to the quantity of fuel burned, and it is in these small plants scattered throughout the country that the greatest benefit would be derived if it were possible to substitute fuel oil for coal.

W. G. Williams.[1] Prior to 1915 fuel oil offered coal keen competition in many parts of the country, but war conditions have placed a different aspect on the situation, and it is safe to say that the present conditions are far more likely to prevail after peace is declared than that pre-war conditions will obtain.

The requirements for petroleum products of the lower end points necessarily keep pace with the growth of the internal-combustion engine; that the production of crude petroleum has not kept pace is evidenced by the reduction of crude in storage. In 1916 there were 162,000,000 bbl. of crude in storage, and

[1] Efficiency Engineer, Empire Gas & Fuel Co., Bartlesville, Okla.

at the present rate of reduction this reserve will be exhausted in 1919.

According to available information, slightly over 300,000,000 bbl. of crude oil were run through American refineries in 1917, and from this 102,000,000 bbl. of gasoline and kerosene, and about 150,000,000 bbl. of gas oil and fuel oil, were produced. This fuel oil (considering gas oil as fuel) corresponds to a coal production of $37\frac{1}{2}$ million tons, which is hardly to be considered in comparison with the actual and known potential production of coal.

Ships May Demand All Fuel Oil Produced

Certain localities and requirements make the use of other than liquid fuel practically out of the question. On the Pacific Coast oil will be used to the exclusion of coal until one of two things occurs—production of crude petroleum falls off, or a method is discovered of converting the output of crude into gasoline. In the marine industry oil is practically the ideal fuel, and with the enormous increase in shipbuilding in the United States it is not too conservative to say that our fuel-oil output is destined for almost exclusive use on shipboard.

It is true that the maximum output of the Mexican fields is still an unknown quantity, and that the known oil fields are only a small part of those yet to be discovered, but against this must be considered the proven life of the fields, and the efforts to convert crude petroleum into gasoline exclusively.

With the gigantic strides that are being made in the application of internal-combustion engines for motive power, the effort to produce a corresponding increase in the fuel for these engines is taking two forms, namely, an increase in production of crude, and of gasoline from the crude. How little these efforts are being rewarded is shown by the decrease in production in the Kansas, Oklahoma, and Texas fields of 82,000 bbl. per day since last October, and the practical failure of the "cracking" processes so far developed.

Any calculations based on the use of petroleum as fuel are, however, rendered valueless by the fact that any hour of any day may witness the development of a new oil field which will produce petroleum in such quantities that its use as fuel would largely supplant coal. The exhaustion of known fields is no bar to the discovery of new and larger producing areas, and I believe it is a wise engineer who keeps this possibility in mind, just as he would the ultimate development of a small steam plant into one of a size to eventually accommodate automatic coal-handling and firing equipment, and I believe this is particularly applicable to those of us doing business west of Pittsburgh.

C. W. Koiner.[1] No relief can be looked for in the East from the substitution of fuel oil for coal except for ocean-going vessels and, possibly, to a limited extent, for the reason that this oil would have to come from the southern and Mexican fields and the conditions in Mexico are so chaotic that the full supply of oil that these fields are capable of putting out cannot be depended upon.

Hydroelectric Plants Interconnected

Practically all hydroelectric plants in California have been linked together from the southern to the northern part, a distance of approximately 800 miles, with a view of eliminating oil-burning plants wherever possible. The oil reserve in California has, during the months of January, February and March, been drawn on to the extent of 1,655,000 bbl. The month of April, however, shows a little improvement. The production has been increased and the lack of shipping facilities for carrying the oil to its destination has prevented the reserve being depleted as much as during the past year.

Vast Deposits of Oil Shale
